Under the ordinary scheme of premiums payable by transfer from the insured's savings bank account the lives of persons of either sex between 14 and 65 years of age may be insured for any amount from £5 up to £100, the lives of children between 8 and 14 years of age may be insured for £5, but children under 8 years of age are not insured. If the amount of the insurance purchased is less than £100 further insurance may be purchased from time to time until the total sum assured is £100. Insurances not exceeding £25 can be effected with or without medical examination.

Meagre Results.—The extent to which advantage has been taken of the Post Office facilities for insurance is indicated by the following table:—

Year ending Dec. 31	No. of policies issued	Amount insured
		£
1911	426	20,040
1916	442	27,258
1921	285	16,153
1927	397	17,994

The total number of contracts in force at the end of 1927 was 10,171, representing sums assured amounting to £511,552.

These meagre results were in marked contrast with the success which since the inception of the scheme has attended the grant of immediate life annuities by the government, both through the National Debt office and through the savings banks. A substantial portion of the total amount of the life annuity business of the United Kingdom has invariably been transacted by the government.

In 1919 a departmental committee was appointed to enquire into the business carried on by Industrial Insurance Companies and Collecting Societies. The committee presented a unanimous report (1920) in which the Post Office system was criticized. Notwithstanding this criticism the scheme remained substantially unaltered.

The Select Committee on Estimates in a report presented to the House of Commons in July 1928, recommended that the Post Office life insurance business should be discontinued.

Subsequently the National Debt Commissioners announced that after December 31 of that year, no further policies would be issued because the volume of business transacted was infinitesimal when compared with that of the big companies, also the energies of the Post Office officials could be more usefully employed in other services. This ruling was put into force in the beginning of 1929.

The country in which Post Office insurance has attained its highest development is Japan, where the undertaking is in effect a national industrial insurance scheme. It is a government monopoly, but it is not compulsory. Postmen act as canvassers and collectors of premiums. The maximum sum assurable is 450 yen and the minimum 20 yen. The premiums are payable monthly either to a post office collector, or at a post office, or by transfer from a savings account. It was inaugurated in 1916, and within 11 years the number of policies in force was over 10 millions and the sums assured amount to about £130 millions. Surpluses have accrued which are being returned to the assured partly in the form of refunds to the policy-holders and partly in establishing and maintaining health and welfare services. (P. G. B.)

INTAGLIO, a term applied to any recessed carving, in which no part projects beyond the original face of the material. In some cases, as in gem cutting, the entire relief is reversed. In others, as in some Egyptian wall carvings, the outline is sufficiently incised so as to allow normal relief. This type is sometimes known as *cavo rilievo* or sunk relief.

INTEGER: see NUMBERS.

INTEGRAL CALCULUS: see CALCULUS.

INTEGRATION, a physiological term, designating the various processes by which the multifarious activities and functions of the organism are knit together to produce a unified individual. The nervous system (*q.v.*) is by far the most important integrative mechanism. By nerve impulses, organs or tissues in one part of the organism are able to exert a co-operative influence on other distant bodily parts. The nerve impulses, in turn, are themselves integrated into harmoniously functioning patterns by action of their common synapses in the central nervous system. Hormones (*q.v.* and see also ENDOCRINOLOGY) are also very important in correlating bodily activities. For integration in mathematics see QUADRATURE.

INTEGUMENT, the cell membrane enveloping the protoplasts of plants. It is composed of cellulose together with a number of other substances known as pectic compounds. In biology the term also implies the skin or external covering of an animal. See PLANTS.

INTELLECT, the general term for the mind in reference to its capacity for understanding (Lat. *intellectus*, from *intelligere*, to understand). See INTELLIGENCE; INTELLECTUALISM.

INTELLECTUAL CO-OPERATION, INTERNATIONAL INSTITUTE OF. In Sept. 1921 the League of Nations, on the proposal of M. Léon Bourgeois, added to its existing technical committees an International Committee on Intellectual Co-operation, made up of distinguished scholars chosen first from 12, afterwards from 14 different countries. Its membership included, among others, Mme. Curie, Prof. Einstein, Prof. Gilbert Murray, M. Jules Destrée and Dr. Millikan. M. Henri Bergson was elected its first chairman. Prof. Gilbert Murray became chairman in July 1928.

The task assigned the committee was that of studying the better organization, through united international effort, of literary, artistic and scientific work. The committee soon became convinced that if it were fully to accomplish its task it must have a permanent administrative organ to prepare its programme and carry out its plans. In 1924 the French Government offered to defray for the League the expenses of such an organ, asking only in return that Paris be its seat. The League accepted the offer; and in Nov. 1925 the International Institute of Intellectual Co-operation opened its offices in Paris, at the Palais Royal.

The Institute is divided into specialized sections which are as follows:

University Relations.—This section organizes annual meetings of the directors of national university offices and of representatives of international students' organizations. It acts as an international university information office and as a link between institutions of higher education in all parts of the world. It organizes vacation courses and other facilities for foreign students; provides for equivalence of degrees, exchange of university professors, national institutes abroad and institutes of foreign studies, and international co-ordination of courses in political science and

international affairs.

Two Sections for Scientific Relations.—A. Science; B. Humanities. These sections deal with specific problems of international scientific organization, such as the co-ordination of libraries, scientific bibliographies, reference books of scientific personalities, etc. Steps are being taken to organize an international special service for libraries attached to the institute. It keeps in touch with the important scientific institutions and learned bodies, and aids them to co-ordinate their efforts. It follows closely the activities of international scientific congresses, and publishes their resolutions and other relevant information about their meetings.

Legal.—This service is chiefly engaged on problems concerning intellectual rights (copyright and scientific property) and, moreover, the legal status of international associations not formed for profit, and in liaison with the International Labour Office the economic position of intellectual workers is being examined.

Literary Relations.—This section is specially interested in the question of translation and of authors' rights, and is actively engaged in preparations for establishing an international office of translation.

Artistic Relations.—This section studies the organization, from an international point of view, of the different aspects of artistic activity. It has established an International Museums' Office which organized the successive exhibitions of engravings from national chalcographies, which was held in different European capitals in 1927, and prepared the first International Congress of Popular Arts held in 1928, in Prague.

Information Section.—This section deals with problems concerning the circulation of books, gives communications to the press and to the public, collects intellectual statistics, publishes an annual list of notable books (since 1924) and, from Jan. 1929, a review *L'Information Intellectuelle*.

Year-Books.—A plan has been drawn up to edit a series of specialized year-books, beginning with an international *Who's Who*.

The Institute has extended hospitality in the Palais Royal to various important international associations which are working in close co-operation in the same field of activity, and has offered its reception-rooms and assistance to several large international congresses.

This organ of the League of Nations is strictly international in character. Its officials belong to about 20 different nations: the director is French, the deputy-director English, the head of the section for University Relations German, that of the Scientific Relations section Dutch, that of the Legal section French, that of the Literary Relations section Swiss and of the Artistic Relations Belgian, while an Italian is head of the Information section.

The Institute does not take the initiative, but attempts to encourage, co-ordinate and assist the countless but diffuse intellectual efforts in each country and to improve the conditions of intellectual work. It aspires to be the rallying-point for intellectuals all over the world who can meet and discuss problems of common interest. (J. L.)

INTELLECTUALISM, a term applied, sometimes in a derogatory sense, to the tendency to emphasize or over-emphasize the importance of thought at the expense of feeling or volition, or even of sensation and intuition. In *moral philosophy* intellectualism tends to identify virtue with knowledge, evil with ignorance. In the *theory of knowledge* intellectualism or rationalism attaches more importance to thought than to sensation or intuition. In *ontology* it conceives the ultimate nature of reality to be some kind of intelligence, or at least regards the universe as intelligible through and through. In *psychology* it treats cognition as the primary mental function, as more fundamental than feeling or volition. In *aesthetics* it stresses the importance of the ideas expressed in, or suggested by, the object of aesthetic appreciation. In the sphere of *religion* intellectualism tends to attach supreme importance to theological doctrine or to religious philosophy rather than to religious sentiment or intuition.

INTELLIGENCE or **UNDERSTANDING** is a term that is still used by psychologists with considerable latitude of meaning. Sometimes it is used as a synonym of "cognition,"

that is to say, it is applied to any of the numerous processes by which knowledge is built up. Sometimes it is restricted to the conceptual processes, as distinct from processes of sense-perception. And sometimes it is used in the still more restricted sense of the process or function of apprehending relations, or even special kinds of relation. In view of the extensive use of so-called "intelligence tests" (*q.v.*) for all sorts of practical purposes, it would seem to be a matter of some urgency to determine as precisely as possible what is meant by intelligence. But that is not the view of many of the investigators in this branch of applied psychology. Some of them frankly admit that they do not know and do not care what this "intelligence" may be which they are measuring, so long as these measurements can be made use of. Others regard it as denoting the average mental ability of an individual in so far as this can be determined by a series of sample tests. Yet others identify it with some "general" ability which the individual possesses, besides certain "special" or "specific" abilities (*see ABILITIES*), and correlate the former with the general stock of "mental energy," and the latter with various "engines," into which this mental energy may be directed alternatively—whatever these physical metaphors may mean. Others again identify intelligence with the apprehension of relations of all kinds, or only with the function of apprehending connections. Lastly, ordinary everyday usage perhaps tends, on the whole, to emphasize the practical character of intelligence as consisting in the ability to employ the right means in order to achieve the various ends pursued.

The view put forward by the present writer is that the terms "intelligence" and "understanding" should be restricted to the mental function of apprehending connections. Such a conception, it is here maintained, is not only most in accord with ordinary usage, but also helps to explain most of the other uses of these terms. In order to make these points clear, it is necessary, first of all, to explain what is meant by *connections*. This term is used in the sense of causal and rational (or logical) relations, or relations of causal and rational (or logical) interdependence. All connections are relations, but not all relations are connections. Such simple relationships between things as, *e.g.*, their similarity or difference are not connections, although they may afford some sort of evidence concerning their connections. Similarly, relations in space and in time are not connections, though these likewise may furnish evidence concerning their connections. The apprehension of these simpler relations seems to call for no other mental functions than those required for ordinary sense-perception. The same processes which render possible, say, the perception of two patches of colour, also render possible our apprehension of their similarity or difference, of their local contiguity or distance, and of their simultaneity or succession. On the other hand, *connections* cannot as a rule be *perceived*, but must be *conceived*. That will explain why most psychologists restrict "intelligence" and "understanding" to conceptual processes. An example or two of our use of these terms will help to elucidate the view here maintained, and will also show its agreement with ordinary usage. By looking at the several parts of a puzzle, or of a lock, one can see their similarities and differences, and their spatial relations, also certain time relations it may be. Everybody with normal sight can perceive that much. But not everybody can grasp, or grasp equally quickly or thoroughly, the *connections* between the various parts of the lock or the puzzle. And ordinary usage would associate the term "intelligence" or "understanding" with an insight into these connections, not with the mere perception of the parts as separate items, or even with the perceptions of relations of similarity or difference, of space and time. Similarly, one would not say that anyone *understands* a proposition in geometry when he has merely learned it by heart, or has just ascertained by measurement that certain properties co-exist in a geometrical figure of a certain kind, but does not apprehend the connection between them. Nor again would anybody be said to understand an historical period or a geographical area if he had merely committed to memory a string of facts without any insight into the causes which produced them. This conception of intelligence will explain

also the common association of the term with the practical application of the right means to achieve one's ends. For it is only when one has an idea of the connections between things, that one knows what methods will produce what results. Similarly with "learning from experience," which is frequently regarded as a test of intelligence. It is only when experience has taught one the connections between things that he has really learned from it; and it is only such learning through insight into connections that is the work of intelligence—the mere formation of habits, even the acquisition of skill through mere repetition need have nothing to do with intelligence.

The apprehension of connections is a distinctive conceptual activity marked by greater spontaneity and originality than are other kinds of cognitive processes, such as sensibility, retention, and even imagination. But it depends upon all these functions for the supply of its raw materials. Similarly, though the apprehension of connections is different from, and superior to, the apprehension of other relations, yet it is usually out of the perception of these other relations (of similarity and difference, of space and time) that there emerges the apprehension of connections. The transition may be illustrated, at the lower level of intelligence, from one of W. Köhler's experiments with a chimpanzee called Sultan (see *The Mentality of Apes*, Eng. trans. p. 8 *seq.*). A long string was tied to the handle of a small open basket containing bananas, and pulled through a ring in the wire roof of the animal's playground so that the basket was suspended about 2 metres above the ground; the free end of the string, tied into a wide, open loop, was laid over a tree-branch about 3 metres distant from the basket, and about the same height from the ground. Sultan was then let into the playground. The animal first looked at the basket, then made for the tree, and climbed up to the loop. Watching the basket, he pulled the string till the basket bumped against the ring in the roof, and repeated the action until the basket turned over and a banana fell out. Thereupon he got down and took the banana. It looks as if the monkey, perceiving the spatial continuity between the rope and the bananas, had some dim apprehension of their connection, and acted accordingly. But even at the highest level of human intelligence, it is the perception of the other simpler relations that affords the clues to the apprehension of connections. The so-called methods of induction and the other methods of science are mainly based upon such clues.

Intelligence varies enormously in two respects, namely, in degree and in range, or in intensity and in extensity. As regards degree or intensity there must be innumerable grades between the dawning intelligence of a chimpanzee and the ripe intelligence of a great thinker. In the former case the awareness of a connection between certain things is probably too dim and vague to be described as more than a feeling; in the latter case it is clear and explicit. Intimately connected with these differences, perhaps only another aspect of them, are differences in what may be called degrees of analysis or freedom, that is, differences analogous to those between "tied" and "free" images. At the lower levels of intelligence, the connections are not yet distinguished from the terms connected, but are fused with them in one concrete situation. At the higher levels of intelligence, the connections are distinguished from their terms, and different kinds of connection may be tentatively applied to certain objects or events in order to explain them—as happens in all cases of rival hypotheses. Then, again, there are differences in the range of facts which intelligence colligates. A chimpanzee may only be able to deal with a very few facts at a time, and with these only in so far as they constitute one concrete situation. The great thinkers have attempted to colligate the infinite variety of things in one system or cosmos. And there are obviously innumerable intermediate grades possible. Differences in respect of range of intelligence are no doubt intimately connected with differences in degree or intensity, for a higher degree of intelligence stimulates an interest in a wider range of facts.

In the History of Philosophy, as distinguished from psychology, quite a variety of speculations may be said to have originated in reflections connected with the subject of intelligence.

The discovery of orderliness in natural phenomena has often been regarded as evidence of the existence of some kind of pervasive intelligence in Nature. In one form or another, such a view was held by Anaxagoras, Heraclitus and the Stoics, among ancient philosophers, and by Maimon and Schelling in modern times. The whole idealistic movement in ancient and modern philosophy has, no doubt, been influenced to some extent by the thought that cosmic order presumes cosmic intelligence. In addition to these ontological speculations concerning the objective subsistence of intelligence in Nature, there are, of course, also speculations affecting the theory of knowledge. It has been argued that since connections are not *perceived*, but only conceived by the intellect or our intelligence, therefore there is no reason for assuming that there are any real connections among natural phenomena. Science should, therefore, confine itself to mere description, and say nothing about alleged connections. Connectedness or orderliness may be something which the human mind fancifully reads into the phenomena of Nature. Some, indeed, have gone so far as to maintain that the alleged discovery of connection or orderliness among natural phenomena is merely an artistic fancy, a veil of Maya, by means of which the human intellect at once decorates its environment and veils those brutal features which would make life unbearable. Others, again, would admit that the orderliness of Nature is indeed the work of intelligence, and that we consequently know nothing about things in themselves, though we may entertain certain beliefs about them in so far as the moral life of man seems to presume them. Perhaps the most reasonable philosophical conclusion one may draw from the development and survival of human intelligence is that there really are connections in Nature, otherwise our intelligence could hardly be an instrument of life, such as even the agnostics and the sceptics maintain that it is. It seems more reasonable to suppose that human intelligence discovers useful connections than that it invents useful delusions—however limited its powers may be.

BIBLIOGRAPHY.—See articles INTELLIGENCE TESTS; ABILITIES, GENERAL AND SPECIAL; PSYCHOLOGY; papers by H. W. Carr, A. Wolf, and C. Spearman on "The Nature of Intelligence," in *Philosophy and Metaphysics* (Aristotelian Society, suppl. vol. v., 1925); C. Spearman, *The Nature of Intelligence* (1924). (A. Wo.)

INTELLIGENCE, MILITARY. Under this designation may be considered the work of obtaining, collating, interpreting and distributing information, in peace and war, about foreign powers, the countering of foreign powers' efforts to obtain intelligence, and the organization which performs these duties. Information as to actual or potential enemies, allies and theatres of war, has always been required and obtained by governments and commanders in the field; the employment of spies, the questioning of prisoners, date from the earliest times in history, but never have the scope, and what might be termed the technique of military intelligence, reached such a high degree of development as in the World War.

I. INTELLIGENCE IN PEACE TIME

In time of peace, the relative military power of a nation with regard to other foreign Powers, and in particular to its immediate neighbours, necessarily affects its foreign policy. Every government therefore maintains an intelligence system, which generally forms a section of the headquarters staff of its military forces (known in most countries as the general staff), for the purpose of: (a) Providing its government with all necessary information regarding the military power of foreign nations; (b) Devising means whereby, in case of war, all essential information concerning the enemy, allies and theatre of war may be placed at the disposal of the commander and troops, and the supply of further information continued throughout the campaign; (c) Preventing the acquisition of information by the enemy.

Type of Information Required.—The fighting power of a nation can only be gauged when accurate and detailed information is available on certain factors, the most important of which are the organization, strength and power of expansion, armament, tactics and morale of its armed forces, the characteristics of its leaders, its defensive works and fortresses, its com-

munications, such as road, railway, waterway, aerodrome, cable, telegraph and wireless telegraphy systems, its physical and political geography, climatic conditions and economic and industrial resources in relation to military requirements. This information also enables the general staff to prepare, and keep up to date, plans for offensive and defensive operations, together with estimates of the forces required for their execution against any Power or combination of Powers, with which the particular Power, either alone or in co-operation with other Powers, might be brought into conflict.

Sources and Value of Information.—The main sources from which information is derived in peace time are statistics and economic data obtained from foreign government publications, from the Press and technical works, foreign training manuals, military and geographical publications and from information procured by the Secret Service. When war breaks out, this intelligence system provides the commander and troops about to take the field with maps and all available information regarding the theatre of war, the armed forces and military resources of allied and hostile Powers, with their special characteristics; this information forms the basis of the plan of campaign, but requires to be supplemented with information concerning the enemy's mobilization, concentration and order of battle in general. For this purpose preparations must be made beforehand and an intelligence organization provided for the troops in the field; the intelligence section therefore lays down the foundation of the intelligence organization required in war and makes arrangements for expansion by training the personnel required.

II. INTELLIGENCE IN WAR TIME

In war, the greatly increased activities of the home or headquarters intelligence service are mainly directed to areas outside the theatre, or theatres, of operations. In the latter, the armies in the field are provided with intelligence services of their own, who form an additional source of information for the home intelligence service, which is responsible for the further collation and distribution of the information thus received.

Field Organization.—In the field, the intelligence section of the general staff collects and collates all information regarding the enemy's forces and intentions and the theatre of war, supplies to the commander, staffs and fighting troops all information which will assist them in preparing and carrying out plans for the defeat of the enemy and endeavours to prevent the acquisition by the enemy of similar information. To be of practical value, the information supplied must be relevant, furnished in time to be of use and in such form as will admit of its immediate application by those concerned. These conditions require the closest co-operation and mutual understanding between the intelligence and operations sections of the general staff. The developments, technical and otherwise, of modern warfare have placed at the disposal of the intelligence section many resources for collecting information which were not available prior to the 1914-18 campaign. Intelligence in the field has become a large and intricate organization, the varied and complex nature of whose duties necessitates the employment, as assistants to the general staff proper, of a large number of highly trained specialists.

Knowledge of the enemy's intentions is of supreme value to a commander, and the intelligence section should therefore possess throughout the campaign early, accurate and continuous information regarding the enemy's "order of battle," his movements of men and war material, his tactical method, armament and equipment, the organization of his defences and rear services, the topography of the theatre of war. The relative value of these different classes of information varies with circumstances; the character of the operations may change at any moment from open warfare to stabilized warfare, or the reverse; an intelligence service must therefore be elastic both in method and organization. Method, accuracy and speed are essential for the collection, reception, transmission and collation of information, but this work is of no value unless timely deductions can be made from the evidence available. The making of deductions, appreciations and forecasts both as to the probable action of the enemy and the

prospect of successful operations undertaken by its own troops is the most important duty of an intelligence section. Its true function, in fact, is to represent the "operations" section of the enemy, for broadly speaking it provides all information concerning the enemy, the allies and the theatre of war, whilst the operations section provides similar information regarding the troops of its own army.

Scope and Nature of Information.—Information regarding the enemy's "order of battle" is of paramount importance. It includes the organization, composition and strength of hostile formations, the direction of their initial concentration and subsequent movements, their distribution, morale and fighting efficiency, the characters of their commanders, methods of recruiting and man-power available to replace wastage. The identification of units is the foundation of all "order of battle" intelligence. Movements of men, supplies and material on a large scale normally portend some important development or a change of the enemy's plans, but as they must take place along organized lines of communication they are difficult to conceal. Detailed knowledge of the enemy's communications system and means of transport is therefore essential; the capacity of railways, quality of roads, navigability of waterways at different seasons, system of aerodromes and auxiliary landing grounds must be carefully studied if reliable conclusions are to be arrived at regarding the size of any movement and the time required for its execution.

Full information regarding the tactics and armament of the enemy at the outbreak of war is usually available by the study of his peace training and organization; but his methods of employing troops and their weapons in the field must be followed very closely in order to discover new developments as early as possible. In the World War full knowledge of each other's pre-war tactics and armament was possessed by the opposing armies, but almost from the beginning of hostilities modifications and new ideas were introduced, which frequently provoked counter-measures. Instances were the employment of poisonous gases, flame and gas projectors, "storm troops," Stokes mortars and tanks. All the economic resources of a State may be required to meet the strain of a prolonged campaign, and accurate knowledge regarding these resources is one of the means of gauging the enemy's staying power.

Sources and Means of Collecting Information.—The main sources of information are prisoners, deserters, local inhabitants, captured documents and material, land reconnaissance and observation, hostile signalling communications, air reconnaissance and photography, the enemy and neutral Press and agents; the principal agencies for its collection are the fighting troops, the signal service, aircraft and secret service. The information, whether positive or negative, acquired by contact with the enemy is that on which every commander mainly relies in making his tactical plan. Hence, to keep the enemy under such close and continuous observation that he can make no movement without being detected is the primary object of all reconnaissance, whether on the ground or from the air.

Ground reconnaissance may be purely topographical, *e.g.*, the acquisition of unmapped information about the ground; it may be tactical, *e.g.*, to discover the enemy's positions, the strength and distribution of his defences, his tactics, movements and intentions; or for the purpose of obtaining "identifications"; *i.e.*, information about the hostile troops in line, their morale, armament and equipment, by the capture of prisoners or documents. These objects are achieved by sending out mobile troops, patrols or raiding parties, or by observation from fixed points. The latter may be visual or instrumental.

Visual observation for intelligence purposes is an organized system for the observation of all enemy activity within the range of vision of its observation posts by trained observers provided with a special equipment of maps, telescopes, periscopes, etc., its elements being generally so placed and co-ordinated that the exact location of the enemy activity recorded can be fixed by intersection, *e.g.*, "flash-spotting." Instrumental observation is mainly automatic, by instruments disposed to receive, transform and transmit impulses from outside; *e.g.*, sound-ranging instal-

lations, electrical listening posts, wireless interception and direction-finding apparatus.

Air Reconnaissance.—Information from the air is derived from balloon observation, aeroplane reconnaissance and air photography. The development of air reconnaissance and photography has to a great extent revolutionized the whole service of military intelligence in the field; not only are aircraft capable of assuming the duty of strategic reconnaissance, but the camera has made it possible to obtain, particularly in position warfare, a far more detailed and exact knowledge of the enemy's system of defence, communication and supply than has ever been possible before. The principal weakness of air reconnaissance and photography lies in their necessary dependence on the weather.

Balloon observation is used principally for the observation of movement by road, railways, and in back areas, of defence works, the location of hostile batteries and the observation of hostile artillery activity. Aeroplane reconnaissance is used at the beginning of a campaign to locate the direction of the enemy's main concentration, to report on the movements and activities of the enemy's troops; and subsequently to supply information on the latter's tactical dispositions, the construction or destruction of bridges, the construction of new defences, etc.

Strategical reconnaissance involves long-distance flights extending frequently to more than 1000 m.; they are usually carried out by single aeroplanes flying at such an altitude as to minimize the chance of hostile interference; at this height, movements of troops on the ground are unnoticeable, and the information gained is largely confined to reports of railway movements, activity at important junctions, formations of large camps, etc. It is often necessary to fly at medium altitudes and to employ formations of aircraft capable of dealing with air opposition, to obtain more detailed strategical information. Tactical information can only be obtained in sufficient detail by aircraft flying low (close reconnaissance) which can be expected to distinguish troops in the open and artillery in action, and can dive near enough to the ground to clear up a definite point, such as the existence of a machine-gun emplacement or whether a trench system is occupied or not.

Photography forms an essential part of all air reconnaissance. Even in the cases of reconnaissances at high altitudes photographs may be expected to show road movements, tracks, camps, new works, battery positions, dumps, hospitals, light railways, telegraph lines and other signs of military activity, while in the case of close reconnaissance carried out at lesser altitudes, photographs taken in favourable weather enable experts to discover the smallest details of the enemy's defences.

III. THE SECRET SERVICE

The secret service supplies information regarding matters behind the enemy's front and in his home territory, including strength and location of reserves, rear defences and lines of communication, internal conditions in the enemy's country and the state of his resources in man power and material.

Secret Service Methods.—The methods employed in this branch of intelligence work can only be referred to in general terms. Broadly speaking, its duties are:—(1) Offensive, in the acquisition of information by means other than those described in Sections I. and II. above; (2) Defensive, in the prevention of the acquisition by foreign Powers of information regarding the forces of its own country.

The duties of the offensive section, to which alone the name of secret service is popularly applied, are similar in peace and war, but war increases the importance, and with it the difficulties and dangers of the work of secret agents or spies.

Agents work *à poste fixe*, on definite missions or on general roving commissions; they penetrate into enemy territory through the ports, in the guise of peaceful neutrals armed with all the necessary papers, or get there by other means, which in war include penetrating the enemy lines, either in uniform or mufti, during the progress of an action; landing behind them from an aeroplane or free balloon or crossing a frontier guarded by sentries and electrified wire. False papers, disguises, secret ink and all the other tricks beloved of the spy novel may form part of their

equipment, but in practice, the most dangerous and efficient spy is the least sensational in his methods; when arrested he invariably has all his papers in order, and is the most plausible person alive. An espionage system in war involves the employment of many thousands of men, women and even children of all grades of society and of all professions: post-boxes, smugglers, guides, train watchers, pigeon men, couriers, runners, etc. All have their part to play, and that part, far from being ignoble, may be, if actuated by patriotism, as noble, as dangerous and as heroic as any played in the armies in the field.

Contre-espionnage.—The duties of the defensive section, popularly described as *contre-espionnage*, are also the same in peace or war, but the machinery and methods vary when carried out in home territory, in occupied enemy or allied territory. The *contre-espionnage* section in home territory commands in peace and war all the assistance of trained police, censorship, port control, hotel registration, the erection of arbitrary barriers such as prohibited areas and of all the preventive measures which are the outcome of years of experience in combating enemy espionage under all conditions. In occupied territory, intelligence in the field equally enjoys these powers, and, in addition, the arbitrary powers of an occupying army, but the whole population is potentially hostile. In allied territory the difficulties are greater, as it is the ally who controls in his own home territory all the real preventive machinery.

The object of *contre-espionnage* is, first and foremost, prevention. Information may be gained by the enemy's agents equally from one's own troops and from the civil population; the former may sell or convey information deliberately, but will more probably convey it to the enemy's agents through indiscretion. "Leakage" may occur in several ways; gossip about impending operations among the troops, especially when on leave and out of the line; indiscreet conversations, messages and misuse of code on field telephones and telegraph; marking of railway trucks, transport and billets, with inscriptions giving identifications of units; indiscretion in correspondence; careless handling of confidential papers and books; taking orders, codes, books, papers of any kind, even private letters into the front line; wearing of badges and numbers, which reveal identifications and in many other analogous ways.

The *contre-espionnage* section is also responsible for the control of the civil population. This involves the control of circulation, of the use of telegraph, telephone and other methods of communication, which might be utilized by enemy agents.

(T. G. G. H.)

INTELLIGENCE IN ANIMALS: *see* ANIMAL BEHAVIOUR; COMPARATIVE PSYCHOLOGY.

INTELLIGENCE TESTS. An intelligence test or intelligence examination is an instrument to measure the amount of intelligence shown by a human being or a lower animal. The instrument consists of a series of questions to be answered, or directions to be followed, or things to be learned, or intellectual tasks of any sort to be performed. Intelligence or intellect may be defined as the ability to perform intellectual tasks; and an intelligence test is a specially instructive sampling of such tasks.

Sample Tests.—The tasks shown below are representative of those used in standard intelligence tests.

"Show me your nose. Put your finger on your nose." Same with eyes, mouth and hair. Three responses out of four must be correct.

What is the difference between: (a) Laziness and idleness; (b) Evolution and revolution; (c) Poverty and misery; (d) Character and reputation.

Repeating three digits. After some explanation and practice, the person tested is asked to say 6-4-1, then to say 3-5-2, then to say 8-3-7. The test is passed if one series out of three is repeated without error, after a single hearing.

Repeating six digits reversed. The series used are 4-7-1-9-5-2, 5-8-3-2-9-4 and 7-5-2-6-3-8. The test is passed if one series out of three is repeated without error.

Tom runs faster than Jim. Jack runs slower than Jim. Which is the slowest of the three?

After some explanation and practice, the person tested is asked to "Finish what I say." At night you sleep in . . . Mary has a ring on her . . . You wear gloves on your . . . You wear a . . . on your head.

A person who has been tested in respect of an examination consisting of from 50 to 200 such tasks may be given a score, and so be put in comparison with all others who have been tested with the same collection of tasks.

Intelligence Quotient.—Subject to certain limitations, the score may be expressed in terms of a mental age, that is, the age at which the average child is able to attain it. Thus if John Doe, aged 12.0, scores 118 in the National Intelligence Examination, and if the average child of age 13.1 attains a score of 118 in this examination, John Doe has a mental age of 13.1 years. John Doe's intelligence quotient, or I.Q. is his mental age $\times 100$ divided by his chronological age, that is $\frac{13.1 \times 100}{12.0}$ or 109.

This form of statement is useful for individuals whose scores are not higher than those made by the average child of 14, and whose chronological ages are not over 18. For higher levels and later ages the method is of doubtful value.

The score may also be expressed in terms of the percentage of some defined group who would attain lower scores than it. Thus, if 71% of persons aged 12.0 score lower than 118, and 29% score higher, in the National Intelligence Examination, John Doe may be recorded as in the 71 percentile for his age. This method is especially useful in the case of the higher levels of intelligence and adult ages. A more refined measure of this type expresses any individual's score as a plus or minus deviation from the average for some defined group in terms of the variability of that group as a unit.

Systems in Use.—There are 30 or more such intelligence examinations now in use. Some, like the Pintner-Cunningham Primary Tests, are adapted to measure very young children aged two to five years. The National Intelligence Examination is designed to fit the intellects of the level of ordinary children from 9 to 15. The Terman Group Test is especially suited to measure young people from 14 to 20. Some, like the Thorndike Examination for High-School Graduates, are adapted to measure gifted adults. Some, like the Army Group Examination Alpha, require an ability to read and write; some, like the Binet, are given orally; some, like the Army Beta, are largely independent of language. Some, like the Otis Group Intelligence Scale, measure chiefly intellect as it operates with words and numbers and abstract relations; some are more concerned with information about things and persons. In some, the speed of response counts a great deal in determining the score made; in others, it counts very little, the time allowed being sufficient to permit almost everybody to do almost everything of which he is capable.

Historical Development.—Existing instruments for measuring intelligence developed from three roots: the tests of sensory acuity, memory, attention and the like devised in the early history of psychology; the interview, as of physician with patient or employer with candidate for employment; and the school examination. Galton, Cattell and Binet were pioneers in this field of psychology. Sir F. Galton's *Inquiries into Human Faculty* (1883) presented the general problem of the measurement of individual differences; and he soon thereafter set up in the South Kensington Museum in London a laboratory where any person could be measured in a series of physical and mental traits. Under the influence especially of Cattell, many short examinations or "tests" of special mental powers were devised and rather widely used in the United States from 1890 on. Important work was done by Kraepelin and Ebbinghaus in Germany. An eminent French psychologist, Alfred Binet, using the general form of an interview between physician and patient, enriched by suggestions from psychological tests proper, produced in 1905 what may be called a standardized interview, consisting of 30 questions and tasks, many of which were chosen from the tests of special powers now familiar to all psychologists. This "metric scale of intelligence" was further improved and divided into age levels in 1908, and finally revised in 1911. Many variations of it have been used in different countries.

While Binet was developing a scientific interview and record and score, various psychologists in America were testing children

in groups by means of printed collections of tests. The next step was the arrangement of such a collection in a standardized unitary examination, after the general plan of written examinations in school subjects. One of the earliest and by far the most influential of such arrangements was the group examination Alpha prepared in 1917 for measuring recruits in the U.S. Army. This examination was taken by nearly 2,000,000 men, large groups (sometimes over 1,000) being sometimes examined at one time and place.

Modes of Use.—Since then, intelligence examinations have increased rapidly in number, have become diversified in nature, and have been much improved in respect of convenience in giving and scoring. They are widely used, especially in the United States, as an aid in the proper grading and classifying and treatment of school children; and in studies of special groups such as defectives, delinquents and dependents. The methods used in conducting intelligence examinations are also being applied to examinations in school subjects, producing the so-called "new-type" examinations and educational achievement tests. At least 1,000,000 such examinations were made in the case of school children alone in the year 1925. Some of the leading American universities require an intelligence examination as a part of the general admission requirement.

In spite of notable improvements during the last 20 years, existing instruments for measuring intelligence suffer from serious deficiencies. An intelligence examination is still a more or less undefined collection of tasks, its score is still a somewhat arbitrary summation of credits, and the correspondence of the scores to the abilities which they purport to measure is still far from perfect. Psychologists are working to supply these deficiencies, seeking to replace the undefined collections of tasks by tasks rigorously defined in nature and graded by a true scale of intellectual difficulty, so that the score may mean the precise height of intellectual difficulty which the person in question can master (see EXAMINATIONS).

INTENDANT, in certain countries an official title having the same general sense as "superintendent" (from Lat. *intendere*, to apply the mind to, watch over). Thus in Germany it is applied to the head of public institutions, e.g., State theatres, and in both France and Germany to certain military offices connected with the *intendance militaire* and *Intendantur* respectively, i.e. the equivalents of the British quartermaster-general's and financial departments of the War Office.

In France the name was used in early times to designate a functionary invested by the king with an important and durable commission. The most famous of these functionaries, however, the intendants of provinces (*intendants des provinces*) date from the last thirty years of the 16th century. Originally used to restore order after the civil wars, their functions were at first extraordinary and temporary; but a few were retained as permanent state officials, and in time they came to be fairly generally distributed over the kingdom. The existing territorial divisions were kept, each *intendant* being placed over a *généralité*, save where slight modifications were necessary for administrative purposes. In the 13th and 14th centuries the monarchy had organized a species of inspection (*chevauchée*) over the provincial functionaries, which was performed by the *maîtres des requêtes*. In the 16th century this inspectorate was revived and passed to the *intendant*, who became the resident supervisor of the other functionaries in his district; its connection with the old *chevauchée*

is plainly shown by the fact that the intendants were almost always selected from the *maîtres des requêtes*. The early intendants had naturally been largely concerned with the troops; eventually special military intendants (the only ones that exist in modern French law) were created, but the *intendants des provinces* retained certain military duties.

The early intendants were called indifferently *intendants de justice* or *intendants de finances*. Their powers were fixed by the commission they received from the king, whose direct general representatives they became in each *généralité*, with authority over the other officials, whom they were empowered to censure, suspend, or sometimes even replace. They were in constant touch with the king's council, with which they were connected by their original rights as *maîtres des requêtes*. In the first half of the 17th century they met with some opposition from the governors of provinces, who had formerly been the direct political representatives of the crown, and also from the parlements, which traditionally intervened in the administration, especially by means of *arrêts de règlement* (decisions, from which there was no appeal, regulating questions of procedure, civil law, or custom). The intendants, however, were energetically supported, and so complete was their triumph that in the 18th century governors of provinces could not enter upon their duties without formal *lettres de résidence*.

The intendants had wide powers in the drawing by lot of the militia and in the royal *corvées* for the making and repair of the high roads, and were largely concerned with the administration of the *taille*, in which they effected useful reforms. They were the sole administrators of the principal direct and indirect imposts created in the second half of the 17th century and in the 18th century, and had full powers to settle disputes arising out of these taxes. Owing to the vast size of the districts allotted to the intendants (there were no more than 32 intendants in 1788), they were allowed to delegate their powers to *sub-délégués*, who were, however, not royal officials, but merely mandatories of the intendant. Decisions of the intendant could be carried to the king's council, and those of the *sub-délégué* to the intendant.

See Gabriel Hanotaux, *Origines de l'institution des intendants des provinces* (1884); D'Arbois de Jubainville, *L'Administration des intendants d'après les archives de l'Aube* (1880).

INTENT, in law, the purpose or object with which an act is done. The question of intent is important with reference both to civil and criminal responsibility. Briefly, it may be said that in criminal law the constituent element of an offence is the *mens rea* or the guilty intent. The commission of an act without the intent is not, as a general rule, sufficient to constitute a crime, nor, on the other hand, does the existence of a guilty intent without commission of the act amount to the legal conception of a crime (see CRIMINAL LAW). In the case of civil wrongs, in general, the opposite holds good. A wrongful act done to the person or property of another carries with it legal liability, irrespective of the motive with which the act was done (see TORT).

INTER-ALLIED CONTROL IN WAR: see WAR CONTROL; ALLIED MARITIME TRANSPORT COUNCIL.

INTER-ALLIED DEBTS. An examination of the methods by which the Allies financed the cost of the World War (that is to say, the difference between normal pre-war expenditure and actual expenditure for the period 1914-19 inclusive) can only give approximate results, but it is estimated that of the total war expenditure 6% was met by taxation, 77.2% by home borrowing, 14.5% by loans between the Allied Governments themselves and 2.3% by borrowing in other foreign countries. In general the funds placed by the Allies at each other's disposal were utilized, not for internal expenditure by the borrowing country, but for purchase in the lending country of military stores and supplies and, in certain cases, for exchange stabilization and interest payments on pre-war external loans. At one time or another during the war all the Allies employed this means of obtaining funds abroad, but only three of the Allied and Associated Powers acted to any appreciable extent as lenders, namely Great Britain, the United States of America and France, the advances made by Italy

being comparatively unimportant. It is extremely difficult to arrive at any accurate estimate of the total sum of these transactions, as the statements published by the various Governments are computed on different bases. In the cases, however, of Great Britain and the United States all the large debts have been funded, with the exception of those due from Russia, so that it is possible to attempt some survey of the whole question. It was only in 1927 that France began to collect the debts due to her and in many cases the amount of these debts is still in dispute.

I. STATEMENT OF LOANS AND FUNDING AGREEMENTS

Great Britain.—For Great Britain the figures in Table II. are taken from the Financial Statement of the Chancellor of the Exchequer, House of Commons report No. 84 of 1925, but the figures in most cases were altered on final adjustment and are only approximate. The Belgian pre-Armistice debt of £110,000,000 is not given, as, under the Treaty of Versailles, this is a charge on German reparations. The figures do not include loans made to the Dominions for war purposes, but do include advances made to certain new and ex-enemy states as well as to Allies, in the period immediately following the war.

Great Britain's only debt to another Allied Government was that of \$4,277,000,000 to the United States. As will be seen from the above, her advances to Allies greatly exceeded the amount borrowed from the United States.

United States.—The United States was a creditor only; and after her entry into the war in April 1917 incurred the main responsibility for financing the Allies, among whom Britain was the principal debtor. After the Armistice large sums were provided by the American Government for relief credits in Central Europe and for purchases of war stores. Table I. shows the total loans to the Allies and other Governments as given in the annual statement of the Secretary of the United States Treasury for 1927.

The majority of these loans have since been the subject of funding agreements, as the following official statement shows:—

TABLE I. *Funding Agreements of Certain Countries with the United States*

Country	Date of funding agreement	Total original indebtedness (principal)	Total debt as funded
		\$	\$
Armenia	11,959,917.49	16,627,153*
Austria	24,055,708.92	34,159,106†
Belgium	18 8 25	379,087,200.43	417,780,000
Cuba	10,000,000.00	Repaid
Czechoslovakia	13 10 25	91,879,671.03	115,000,000
Estonia	28 10 25	13,999,145.60	13,830,000
Finland	1 5 23	8,281,926.17	9,000,000
France	29 4 26	3,404,818,945.01	4,025,000,000
Great Britain	19 6 23	4,277,000,000.00	4,600,000,000
Greece	15,000,000.00	19,659,830*
Hungary	25 4 24	1,685,835.61	1,939,000
Italy	14 11 25	1,648,034,050.90	2,042,000,000
Latvia	24 9 25	5,132,287.14	5,775,000
Liberia	26,000.00	Repaid
Lithuania	22 9 24	4,981,628.03	6,030,000
Nicaragua	431,849.14	299,128*
Poland	14 11 24	159,666,972.39	178,560,000
Rumania	4 12 25	37,922,675.42	44,590,000
Russia	192,601,297.37	280,197,301*
Yugoslavia	3 5 26	51,758,486.55	62,850,000
Total	10,338,323,597.20	11,872,596,524

*Not funded: debt as on Nov. 15, 1927.

†Time of payment of principal and interest extended to June 1, 1943, by authority of Joint Resolution of Congress approved on April 6, 1922. Debt as on Nov. 15, 1927.

France.—The position of France, which, like Great Britain, was both a borrower and a lender, is more obscure. It was only in July 1929 that France ratified the funding agreements made with either Great Britain, from whom she borrowed £446,226,000, or the United States, from whom she received \$3,404,000,000. On the other hand, she advanced considerable sums to Russia and the smaller Allies; here, too, no refunding arrangements have been made, and in many cases the exact amount is in dispute.

INTER-ALLIED DEBTS

463

TABLE II. GREAT BRITAIN: I. War Debts

Country	Original Advances*	Debt as funded† (including interest added to capital)	
1. France	£ 446,266,000	£ 600,000,000	(Debt on March 31, 1927.)
2. Russia	483,321,000	783,000,000	
3. Italy	369,824,000	570,000,000	
4. Yugoslavia	22,383,000	25,591,000	
5. Rumania	16,401,000	18,448,000	
6. Portugal	15,611,000	20,154,000	
7. Greece	16,391,000	21,441,000	
8. Belgium: Pre-Armistice	90,084,000	99,133,000	(Pre-Armistice debt as on May 1, 1921, taken over by Germany.)
do. Post-Armistice	6,799,000	..	(Post-Armistice debt repaid in cash.)
	1,467,040,000	2,137,747,000	
2. Loans for Reconstruction and Relief			
1. Belgium	£ 9,000,000	£ 9,000,000	(£2,250,000 repaid in 1923: balance postponed until 1943.)
2. Belgian Congo	3,550,000	3,550,000	
3. Austria	11,578,000	12,727,000	
4. Rumania	1,892,000	2,200,000	
5. Yugoslavia	1,884,000	2,069,000	
6. Poland	3,682,000	4,770,000	
7. Czechoslovakia	461,000	474,000	
8. Estonia	241,000	251,000	(Repaid in cash.)
9. Hungary	109,000	109,000	
10. Armenia	88,000	125,000	
11. Lithuania	17,000	..	
12. Latvia	20,000	..	
	32,522,000	35,275,000	
3. Loans for Stores and Repatriation (Post-War)			
1. France	£ 8,226,000	£ 8,226,000	(£5,976,000 repaid by 1927) (Interest waived.)
2. Latvia	1,303,000	1,303,000	
3. Estonia	917,000	917,000	
4. Czechoslovakia	827,000	827,000	
5. Lithuania	348,000	150,000	
6. Poland	174,000	174,000	
7. Greece	108,000	108,000	
8. Rumania	36,000	36,000	
9. Armenia	747,000	1,001,000	
	12,686,000	12,940,000	
Total	1,512,248,000	2,185,764,000	

*See Hansard (House of Commons) July 23, 1925, Col. 2445-6. (The figures were in most cases altered on final adjustment and must be regarded as approximate.)

†See published Funding Agreements: the amounts of the gold deposits (viz., France £53,500,000, Russia £60,000,000 and Italy £22,200,000) are deducted.

The Budget Project for 1928 set forth the debts owing to France by various foreign countries, as of Dec. 31, 1926, as follows:—

(1) Debts in French Currency	Franks
Russia (Tsarist Government)	7,008,928,000
Russia (various local Governments)	416,233,000
Yugoslavia	1,946,042,000
Rumania	1,050,000,000
Greece	812,457,000
Poland	1,047,120,000
Czechoslovakia	474,124,000
Italy	1,145,737,000
Portugal	9,050,000
Lithuania	8,800,000
Hungary	319,000
Austria	379,000
Georgia	200,000
Albania	1,800,000
	fcs. 13,921,189,000

(2) Debts in Foreign Currencies		
Russia (various local Governments)	gold roubles	10,533,145
Czechoslovakia	dollars	1,149,000
Italy	lire	16,983,000
do.	£ sterling	18,826
Austria	dollars	16,000,000
do.	lire	35,000,000

Except in the case of the franc debt of Tsarist Russia the figures apparently exclude interest. No account is here taken of counter-claims which are of considerable importance in certain cases.

Italy.—Italy was in the main a borrower, although to some extent she made advances to other Allies. After her entry into the war in May 1915 she borrowed from Britain £369,824,000 and from the United States \$1,648,054,050. According to official figures her loans to other Allies were as follows, but certain of the items in the French account are in dispute. Foreign currencies are converted at the rates ruling on April 23, 1926:—

	In thousand lire
Rumania	189,936
France	292,380
Russia	63,000
Yugoslavia	56,000
Greece	5,000
Austria	1,730,000
	2,336,316

Russia.—Russia, on the other hand, was entirely a borrower. Her loans from Allied Governments up to the time of the revolution in 1917 were as follows:—

Great Britain	£483,321,000
United States	\$187,729,750
France	fr. 6,023,300,000
Italy	lire 36,045,000

Other Allies.—Belgium was also a borrower, and received considerable sums from the United States, Great Britain and France. As a recognition, however, of the damage done consequent on the violation of the treaty of 1839, Germany undertook in Article 232 of the Treaty of Versailles "to make reimbursement of all sums which Belgium has borrowed from the Allied and Associated Governments up to Nov. 11, 1918, together with interest at the rate of 5% per annum on such sums." At the time of the Peace Conference the representatives of Great Britain, France and the United States agreed, subject to ratification by their Governments, to accept German bonds to the value of the Allied pre-Armistice loans to Belgium thus freeing Belgium from the responsibility of these debts. This was eventually carried out by Great Britain and France. The United States Congress, however, refused to ratify the agreement, and the pre-Armistice debt was the subject of a special arrangement in the subsequent Belgian Debt Funding agreement. For the sake of convenience, the following table gives the advances made by each of the Allies during both periods:—

	<i>Pre-Armistice</i>	<i>Post-Armistice</i>
Great Britain	£110,000,000*	£18,500,000
United States of America	\$171,780,000	\$207,307,200
France	fr. 3,219,474,742*	fr. 241,472,300

*Including interest at 5%.

Of the other Allies, Rumania, Yugoslavia, Greece, Portugal, Armenia, Nicaragua and Liberia were all borrowers, while after the Armistice the new states of Poland, Czechoslovakia, Finland, Lithuania, Latvia and Estonia received advances for various purposes, and Austria and Hungary, of the ex-enemy states, received relief credits. The actual amounts lent can be seen from the preceding tables.

II. HISTORY OF THE LOANS

Any attempt to trace in detail the development of Inter-Allied borrowings, of which the above official figures represent the present position, must be one of great difficulty. For a considerable part no authoritative information has been made available as to the dates at which these various obligations were incurred, and the figures given in the following survey must be taken as mere estimates. For the sake of convenience the history of these loans may be divided into three periods:—

First Period: 1914-17.—Up to the end of 1914 the various Allies were able in the main to finance their own foreign purchases. Russia, however, soon found herself in difficulties. Unlike Great Britain and France, her Government was unable to command large funds abroad, while her incapacity to manufacture munitions on a sufficiently large scale necessitated heavy purchases from her Allies. In addition, considerable sums were required for the payment of interest on the existing external debt. As early as Oct. 1914 she had been forced to apply to the British Government for assistance, and a credit of some £11,500,000 was opened on her account at the Bank of England against a shipment of gold to the value of £8,000,000. At the end of the year a further credit was granted, and in Feb. 1915 at a meeting in Paris the British, French and Russian Finance Ministers agreed to unite their financial resources, to share the advances made to Allied Governments, to issue a joint loan and to co-operate in the purchase of supplies abroad. Actually the second proposal was never carried out, but as a result of this and subsequent conferences large funds were raised for Russia in both France and England by the sale of Russian Treasury Bills on the open market and by the extension of governmental credits against a small proportion of gold from the Russian reserve. It is estimated that Russia, during the period 1914-Sept. 1917, borrowed £483,000,000 from the British Government, against a deposit of gold in London of £60,000,000, and 6,000,000,000 fr. from the French Government. She also obtained advances from the United States Government between the months of April and Sept. 1917. In the United States and Japan, more-

over, considerable sums were placed at her disposal by the British Government.

The next country to find difficulty in financing its war requirements abroad was France. In Oct. 1914 she had found it advisable to arrange for the issue of Treasury Bills on the London market. By May 1915 some £10,000,000 worth of these bills had been placed, and by the end of that year the figure of open market borrowings had risen to £33,000,000 and to £80,000,000 in 1917. In May 1915 it was agreed that the British Government should grant France substantial credits against shipments of gold in the proportion of three to one. This system lasted until the end of 1916, when the shipment of gold ceased. During the same period France raised considerable sums on the American market, of which the most important was the joint Anglo-French loan for \$500,000,000 in Oct. 1915, repaid in 1920. France, during this period, borrowed altogether nearly £200,000,000 from the British Government and dispatched to London some £53,500,000 in gold. To the other Allies the French Government lent approximately 6,500,000,000 francs.

Great Britain during this period loaned to her Allies over £900,000,000. In addition to the above-mentioned advances to France and Russia, £60,000,000 were advanced to Belgium and £27,000,000 to Rumania, Serbia, Greece and Portugal. Up to Oct. 1915 Great Britain had not had occasion to borrow in the United States, but it was found impossible to maintain the American exchange unless funds were available to cover the greatly increased purchases there of war materials. The joint Anglo-French loan was raised on the market without other security than the credit of the two governments, but all moneys subsequently raised in America during this period took the form of credits or secured notes, collateral being deposited in each case. For this purpose the British and French Governments encouraged their nationals either to sell or lend to the Government their holdings of American securities, which were either sold for dollars or employed as collateral.

Italy did not enter the war until May 1915, and from then until the end of this period confined her borrowing to the United Kingdom (with the exception of a small amount raised in Canada). Credits to the extent of some £153,000,000 were granted to her by the British Government, gold to the value of £22,200,000 being deposited in London as security. On the other hand, she herself advanced about 63,000,000 lire to Russia. Her advances to France during this period are in dispute.

The Second Period.—This dates from April 1917, when the United States entered the war, till the Armistice in Nov. 1918. Towards the end of the previous period the Allies were beginning to grow anxious as to their ability to continue the purchase of supplies in America on the then existing scale for an indefinite period. Accordingly, one of the first acts of the United States Government after the declaration of war was to obtain the consent of Congress to a law (Liberty Loan Act) authorizing the extension of credits to Allied Governments up to a total of \$3,000,000,000. This limit was subsequently raised three times up to a total of ten thousand million dollars in July 1918. Such credits were granted without any collateral and they were to bear the same rate of interest and be subject to the same conditions as the corresponding bonds to be issued on the United States market in order to raise the sums required. From that time the American Government assumed the responsibility for Allied purchases in the United States. Market borrowings by the Allies ceased with the exception of certain small amounts required for the purpose of refunding existing market loans, some of which, however, were also paid off with the funds obtained from the new credits.

The total advances by the United States Government to the governments of the Allies amounted during this period to some \$7,077,000,000, of which Great Britain received approximately \$3,696,000,000, France \$1,970,000,000, Italy \$1,030,000,000 and Belgium \$171,780,000. The Provisional Government of Russia (successors to the Tsarist Government) received \$188,000,000 between April and Nov. 1917. Smaller Allies account for the remainder. During the same period the British Government continued to finance the requirements of the Allies in the United Kingdom, and also assisted them by the employment, to a certain

extent, of the credits extended to her in America. These credits were principally employed for the purchase there of raw materials required for the manufacture in the United Kingdom of war supplies for the Allies. For, as the needs of the United States army increased, her ability to meet all the Allied requirements decreased to some extent, and Great Britain endeavoured to take her place. In Aug. 1918, however, it was arranged that each Ally should be debited by America with the cost of the necessary raw materials. In addition, during the early part of 1917 Great Britain advanced funds from her American credits to the Russian Government for interest payments due in America. Total loans by Great Britain to her Allies during these years amounted to over £550,000,000, of which France borrowed nearly £250,000,000, Italy £220,000,000 and Belgium £50,000,000. France, on the other hand, in addition to the advances made by Great Britain, borrowed nearly \$2,000,000,000 from the United States, and loaned to her other Allies nearly 7,000,000,000 francs. Italy, Russia, Belgium, Serbia and Rumania were all borrowing nations.

Third Period: Nov. 1918–Sept. 1920.—Although the Armistice was signed on Nov. 11, 1918, nearly two years elapsed before it was possible for the lending Governments to cease making advances to the other Allies for the payment of goods already supplied or ordered. They were also required to enable the Allies to purchase war stores left by the lending Governments in their territories. In addition, the impoverished condition of Europe made it essential, if complete economic chaos were to be avoided, for relief credits for the purchase of foodstuffs and for reconstruction to be granted not only to the poorer Allies but also to certain of the new states created by the peace treaties, and even to some of the enemy countries.

In the United States there was some doubt after the Armistice as to the legality of granting further credits under the Liberty Loan Acts. These Acts limited credits to the period of the war, and Congress had refused to approve any prolongation. On the other hand, the presidential proclamation announcing the official termination of the war was not published until July 2, 1921, and the Administration felt themselves justified in continuing to make advances during the intervening period. The balance of \$2,500,000,000 authorized under the Acts was, in this way, advanced to the Allies and utilized by them partly to meet existing contracts in America and partly for the purchase of supplies for the relief of Europe. Moreover, special credits were granted with the approval of Congress to the extent of \$740,000,000, of which \$600,000,000 were utilized for the sale of war stores to Allied Governments, and \$140,000,000 for the sale of flour through the United States Grain Corporation. To this must be added a revolving credit of \$100,000,000 opened in favour of the American Relief Administration, of which \$84,000,000 was expended for relief supplies furnished on credit.

Relief and reconstruction loans by the British Government amounted during this period to £32,522,000, loans for the purchase of war stores to £12,205,200 and for the repatriation of prisoners to £1,450,000. Similar advances by France amounted to some 1,500,000,000 fr. and by Italy to approximately 600,000,000 lire.

III. THE DEBT SETTLEMENTS

Before even the last inter-Ally loans had been made, it was clear that the problem of repayment would assume an importance in international politics second only to the question of reparations. Soon after the Armistice it became known that the British Government favoured a general cancellation of inter-Ally debts, but the United States was not prepared to agree to such a course. In May 1920 the inter-Ally Conference on Reparations at Hythe declared that it was "important to arrive at a settlement which will embrace the whole body of the international liabilities which have been left as a legacy of the war, and which will at the same time ensure a parallel liquidation of the inter-Ally war debts and of the reparation debts of the Central Empires." This was followed, however, a few days later by a statement by the Chancellor of the Exchequer in the House of Commons to the effect that the question of the United Kingdom debt to the United States of America was being dealt with independently of any question of

the part of this country's share of indemnity from Germany. By 1922 the different points of view of the various Allied and Associated Powers on this subject became clearly defined. On Feb. 9 of that year the American Foreign Debt Funding Bill was signed, authorizing the refunding of Allied debts to the extent of \$11,000,000,000 into securities with a maximum currency of 25 years, carrying interest at a rate of not less than 4½%, the negotiations to be carried out by a commission of five members (subsequently increased to eight) under the chairmanship of the Secretary to the Treasury. It was, at the same time, made clear that the United States Government would not consider the remission of debts due to them from the Allies but would look for repayment, though it was recognized that immediate payments would not be possible in every case. This action had a determining effect on the attitude of the Powers concerned towards the whole problem of inter-Ally debts.

The Balfour Note.—Great Britain, which had hitherto made no final pronouncement of policy, was now faced with the necessity of funding her debt to America, and consequently compelled to lay down a principle for dealing with her own debtors. Accordingly, on Aug. 1, 1922, a Note was dispatched to the Governments concerned which has since formed the basis of British policy. In this communication, commonly known as the "Balfour Note," it was stated that, while Great Britain would have been willing to forego all claims for reparations and the repayment of inter-Ally debts if this had formed part of an universal settlement, she must now ask for some measure of repayment. She would, however, be content with a total sum from her Allies and Germany sufficient to cover her own payments to the United States, though this was equivalent to only one quarter of the amount due to her. The French reply in Sept. was inconclusive and unsatisfactory, and the policy of that country was definitely revealed in Oct. at a meeting of the Reparations Commission.

At this meeting certain proposals were submitted by the British delegate for the settlement of the reparations problem, provided that the question of inter-Ally debts was settled at the same time. The French delegate rejected this scheme and put forward a counter-proposal which definitely made the payment of inter-Ally debts dependent on receipts from reparations. At the inter-Allied Conference in London in Dec. 1922 Signor Mussolini, on behalf of Italy, proposed the cancellation of part of Germany's reparation liability if Great Britain would agree to the cancellation of the debts due to her from her Allies. Poincaré elaborated this scheme and offered to hand over forthwith part of the French claim on Germany in payment of her debt to Great Britain and to accept similar terms from her own Allied debtors. Both these proposals were rejected by Bonar Law. The discussion was continued at the Paris Conference on Reparations in Jan. 1923. At this conference the French Government reiterated the principle of the dependence of inter-Ally repayments on German reparations.

The British proposal, which was contingent on the acceptance of their plan for the solution of the reparations question, rested on the basis of the remission of all European Allied debts to the United Kingdom except a small percentage which was to be paid in German obligations, while all German payments over a fixed minimum were to be available for the repayment of European debts to the United States. The failure of the Paris Conference, which was followed by the French occupation of the Ruhr, marked the last attempt to reach any common basis of agreement on this question, although the question was dealt with in the British Note of Aug. 11, 1923 addressed to the French and Belgian Governments regarding the occupation of the Ruhr. In this document the British Government offered as part of a general settlement of the Reparation question to accept in full payment of both reparation and Allied debts a sum equivalent to the amount necessary to cover the funded British debt to the United States, which was estimated on a 5% basis at 14.2 milliards of gold marks. The proposals contained in this Note were not accepted by the Allied Governments concerned.

Anglo-American Funding Agreement.—Meanwhile, the constitution of the United States Funding Commission in Feb. 1922 was immediately followed by preliminary discussions between

the British and American Governments regarding the debt due from the United Kingdom. It was finally arranged that a British delegation, under Sir Robert Horne (the then Chancellor of the Exchequer), should leave for Washington in Oct. with the object of negotiating a settlement. Owing to the change of Government in Great Britain, its departure was postponed, but a payment of \$100,000,000 was made on account—the first Allied payment in respect of interest on war debts. The mission finally sailed early in Jan. 1923 under Mr. Baldwin (the new Chancellor of the Exchequer), and returned to England at the end of the month with a proposed settlement which was accepted by the Cabinet on Jan. 31. Under the terms of this agreement the whole principal sum, which after allowing for interest due to Dec. 15, 1922 at 4½% per annum and for payments already made, was agreed upon at \$4,600,000,000, is to be repaid over a period of 62 years in annual instalments increasing from \$23,000,000 in the first year to \$175,000,000 in the last. Interest is to be paid at the rate of 3% per annum on unpaid balances for the first 10 years and at 3½% for the remainder of the period. The total annual payments on account of interest and principal vary between \$160,000,000 and \$187,000,000. Britain may rightfully defer half the interest accruing during the first five years, to anticipate payments and to make payments in U.S. Government bonds issued subsequent to April 1917. As these terms were not in accordance with those which the United States Debt Funding Commission was authorized to accept, it became necessary for Congress to approve the agreement, which was done on Feb. 28. On June 15 the first payment under the scheme was made by Great Britain.

Other Funding Agreements.—While the British negotiations were in progress, the United States administration had made their wish to be repaid known to the other countries concerned. The first country to respond was France, which in July 1923 dispatched a mission under M. Parmentier to Washington. No basis of settlement, however, was reached, and negotiations with the Czechoslovak Government led to the same negative result. In Oct. the Administration, hearing that the Rumanian Government contemplated raising a foreign loan, protested against such action before the American Relief Debt was funded. A Rumanian mission subsequently visited the United States, but failed to come to terms. In May 1923 an agreement was reached with Finland for the funding of its debt of \$8,000,000 on the same terms as those accorded to Great Britain. No further settlements were reached until 1924, when an agreement was signed in April with Hungary for the refunding of the Relief credits to the extent of \$1,939,000 on similar terms to those accorded to Great Britain and Finland. This was followed by settlements with Lithuania and Poland.

In Dec. 1924 the authority of the Debt Funding Commission was extended for another two years and in the following May a *démarche* was made by the United States Government to induce the governments whose debts were still unfunded to negotiate for repayment on the basis of the capacity to pay of the debtor. Consequently, in the latter part of 1925 the majority of the remaining Allies either came to terms or initiated discussions. Thus in Aug. a Belgian delegation arrived at Washington and an agreement was shortly reached by which the debt was divided into two parts. The pre-Armistice debt of \$171,780,000 was treated specially, as by the Treaty of Versailles Germany must pay the Belgian war debt as part of her reparations. Belgium undertakes to repay this sum in full over a period of 62 years, but no interest is payable. The post-Armistice debt of \$246,000,000 is also to be repaid in full over 62 years, and in addition interest is to be paid at a rate which rises from ⅔ of 1% in the first year to 1% in the tenth year and at the rate of 3½% thereafter.

In Oct. an agreement was reached with the Czechoslovak Government which fixed the debt due at June 1925 as \$115,000,000, repayable on terms similar to those reached with Great Britain. Latvia had already signed an agreement in September, and was followed by Estonia in October. In November an Italian delegation signed an agreement which fixed the principal sum due at \$2,042 million to be repaid over a period of 62 years. Interest, however, will not be paid during the first 5 years, and thereafter only at a rate rising by 10-year periods from one-eighth of 1% to 2% per

annum, or an average of just under 1% per annum for the whole time. This was followed in December by a settlement with Rumania, on the British model.

The French Debt.—Meanwhile, the French Government, which, since the failure of M. Parmentier's mission in 1922, had made no move with regard to the refunding of its debt to the United States Government, dispatched in Sept. 1925 a mission under M. Caillaux (the then Minister of Finance), but the proposals put forward at that time were unacceptable. Better fortune attended the next attempt. On April 29, 1926, an agreement was signed. France agreed to the total at \$4,025,000,000 and undertook to pay a total sum of \$6,847,674,104 over a period of 62 years, beginning at \$30,000,000 for 1926 and rising to \$125,000,000 for the seventeenth and subsequent years. No interest is payable until June 15, 1930, after which one per cent will be paid to June 15, 1940, 2% to June 15, 1950, 2½% to June 15, 1958, 3% to 1965 and 3½% thereafter. This agreement was not ratified by the French parliament until July 1929, but payments at the rate therein laid down had been regularly made in the interim.

All the remaining debtors, including Yugoslavia, Greece, Estonia and Latvia, have since concluded agreements on similar terms, with the exception of Russia, Armenia, Greece and Austria. For the last special arrangements for postponement have been made. If the settlements which have already been made are considered, it will be seen that the terms of the Debt Funding bill with regard to the repayment of capital in full have been carried out in each case, and that, where concessions have been made, they have taken the form of a reduction in the rate of interest. Thus, Great Britain is paying 76% of the 4½% per annum laid down by the law, while Belgium pays 48% and Italy 25½%. These agreements were ratified by Congress early in 1926.

Debts to Great Britain.—Up to the end of 1924 little or no progress had been made with regard to the repayment of debts due to Great Britain from her Allies. In December of that year the Chancellor of the Exchequer (Winston Churchill) made an official statement to the effect that Great Britain would expect any country making a funding agreement with the United States to come to terms, *pari passu*, with his country. As a result, the French Government took advantage of Churchill's presence in Paris in Jan. 1925, at a financial conference on the Ruhr and the Dawes scheme, to state their intention of opening negotiations and to ask for a definition of the British position. An official reply in February adhered to the principle of the Balfour Note, while no longer supporting the proposals contained in Lord Curzon's Note of Aug. 1923 on the ground that they were out of date. It further proposed that France should pay fixed annual amounts from her own resources, together with a further annuity based on the French share of the Dawes annuities. Direct negotiations were resumed in London in July, when Churchill proposed the payment by France for 62 years of an annuity of £20,000,000, subsequently reduced to £16,000,000 and only a small proportion of which was based on payments to France under the Dawes scheme. Caillaux's counter-proposal of £10,000,000 led eventually to a compromise on a basis of an annual payment for 62 years of £12,500,000. This proposal, which reduced the French debt to Great Britain by nearly two-thirds, was referred by Caillaux to the French Government, which, however, resigned before a final decision had been taken. French opinion was subsequently moved towards the hope of obtaining better conditions by the terms of the Italian agreement with Great Britain and in July 1926, M. Caillaux, who was again Minister of Finance, re-opened negotiations. An agreement was eventually reached by which France agreed to pay a sum of £4,000,000 in 1926-7 which would rise by annual increment of £2,000,000 to £10,000,000 in 1929-30. From 1930-31 to 1956-7 she must pay £12,500,000 annually and from 1957-8 to 1978-9 £14,000,000 annually. She may also postpone half the annual payment for the first three years and by means of a separate letter, reserved to herself the right to ask for a revision of the terms if receipts from Germany did not amount to half the figure laid down in the Dawes scheme. On the other hand, the gold deposit of £53,500,000 was retained by Great Britain (the debt due from France being similarly reduced), until a separate agreement could

be reached. Although the debt agreement was only ratified in France in July 1929, the annual payments had been made.

By an agreement signed on Jan. 27, 1926, the total amount of the Italian debt at that date was calculated at £610,840,000, and it was agreed that Italy should pay 62 annual payments of £4,500,000 with a partial moratorium for the first seven years. In addition, the Italian gold to the extent of £22,200,000 which had been deposited in the Bank of England as part security for certain loans is to be returned to her by instalments over the same period. It will be seen that, while the total amount to be repaid is not so great in proportion as that which the United States will receive, the present value is about the same. Of other debtors Belgium has repaid her post-Armistice debts, and Rumania has reached an agreement on the same basis as that of the offer to France in Aug. 1925, while Yugoslavia, Greece and Portugal have also come to terms. Russia alone has made no move. As far as relief credits and credits for stores are concerned, Lithuania and Latvia repaid the amount due on Jan. 1, 1925, while funding agreements for the full amount have been concluded with Poland, Czechoslovakia, Estonia, Hungary, Rumania, Yugoslavia and Greece.

Although it is the declared policy of both Great Britain and the United States to treat the problem of inter-Ally debts as entirely separate from that of reparations, the doctrine of repayment according to capacity, enunciated by the United States, has led to results which are not without interest. Great Britain has advanced to her Allies a total sum of £1,423,132,000, and, on the basis of the arrangements already concluded with her debtors, will receive a total sum on account of both principal and interest of £1,147,000,000 in the form of annual payments over a period of 62 years of £18,500,000. On the other hand, she borrowed from the United States approximately £960,000,000, on which she is now paying £30,000,000 and will later have to pay £38,000,000 per annum, so that, in effect, although she lent over 50% more than she borrowed, she will receive from her Allies less than half the amount which she must in her turn pay. Even if she receives her full share of £20,000,000 per annum of German reparation payments under the Dawes scheme (which is a very optimistic estimate), her total receipts on account of inter-Ally debts and reparations combined would only just cover her payments to America. On the other hand, it is interesting to note that the United States should eventually receive on account of loans to her Allies an annual sum equivalent to 65% of that payable annually by Germany in a standard year under the Dawes scheme in respect of reparations. (R. J. S.)

INTER-ALLY COUNCIL OF WAR PURCHASES AND FINANCE. Before the United States entered the World War, natural, if imperfect, checks on wasteful and unco-ordinated Allied purchases of supplies both in North America and neutral countries were exercised by the limited amount of foreign purchasing power and of shipping available. A certain degree of government control of commodities and of joint purchasing by Allied Governments, destined, as will be mentioned later, to be considerably extended, reinforced these natural checks.

The checks operated with particularly ruthless severity in the case of purchases in America. To a large extent the financial re-

striction was removed when the United States entered the war, and every spending department, naturally, and indeed, properly, imbued with the conviction that its own requirements were of primary importance for the successful prosecution of the war, prepared an ambitious programme for the future. The United States Government had a double interest in restraining any undue ardour to spend; in the first place it provided on credit a large proportion of the funds required to finance purchases by Allied Governments abroad, and was concerned to be able to satisfy American public opinion that the advances made were expended in the manner best calculated to promote victory; in the second place, it had itself become a large purchaser of war material and equipment, and the first effect of its entrance into the war was to increase the demand more rapidly than the supply. A newcomer had appeared on a restricted market, and it was highly desirable that competition should so far as possible be eliminated and replaced by carefully co-ordinated purchases.

Such were the conditions which induced the Allied Governments in the late summer of 1917 to set up, at the instigation of the United States Government, the Inter-Ally (or Inter-Allied, as it was commonly called in British documents) Council on War Purchases and Finance. In correspondence with the twofold interest of the United States Government described above, the professed objects of the council were firstly to make recommendations as to the supplies and finance required by the various Allies in the United States itself, and secondly to deal, in an advisory capacity, with the problems involved by Allied purchases of all kinds in the world at large.

The council set up two offices, the more important being housed in London in Sunderland House, and the other in Paris. The president was *ex officio* the delegate of the United States Government on the council, and throughout the period of its activity this post was held by Mr. Oscar T. Crosby, who had vacated the post of assistant secretary of the United States Treasury to assume that of special finance commissioner of the United States in Europe. Mr. Paul Cravath assisted him in the capacity of advisory counsel; to his tact it was largely due that the serious friction which the council at times threatened to produce was avoided. The post of secretary-general in London was filled by Mr. H. J. Cook, and that in Paris by Mr. Max Lazard. The British members of the council were Mr. (later Sir) Austen Chamberlain, General Smuts, and Lord Buckmaster. In general the other Allied members were drawn from the representatives of the respective governments on the Commission Internationale du Ravitaillement (*q.v.*).

The Council at Work.—The first object of the council was, as described above, to satisfy public opinion in the United States. That this object was substantially attained may perhaps be inferred from the following reference to the council in the "Annual Report of the Secretary of the (U.S.) Treasury on the State of the Finance for the Fiscal Year ended June 30, 1918": "Valuable information as to the needs of the Governments of the Allies for war purposes, their urgency and the necessity of meeting them from advances by the U.S. has been furnished from Europe by the Inter-Ally Council on War Purchases and Finance and by its president, Oscar T. Crosby." It is proper to add that the required information was given more expeditiously by the special financial representatives appointed by the principal Allied Governments to be in direct touch with the United States Treasury authorities in Washington, and that the value of the council's information was chiefly psychological.

In relation to its second object, the control and co-ordination of the purchase of supplies, the council may have been said to have succeeded by failing. The council's task, as originally conceived, was grandiose and quite unworkable; it represented a Treasury ideal unattainable in practice. The council met every few months and had laid before it imposing sheets, necessarily prepared some time before, which should in principle have set out purchasing programmes of the principal governments for almost every conceivable supply required, not only by the war departments proper but also by civilian departments such as the British ministry of food, which were gradually extending a strict

control over one class of commodity after another. It was inevitable that in the circumstances the figures laid before the council were largely out of date before their preparation was complete. They could hardly be a picture of proposed orders, for the war had to be prosecuted, and needs which altered daily with the war's changing circumstances called for daily control and immediate decision. In fact the figures represented orders in course of fulfilment, commitments long entered into, proposals which might never be proceeded with, and projects, which, even if approved, would have to be abandoned for want of shipping.

This last word reminds us of the real seat of control at this stage of the war. The entry of the United States had relieved the Allies from their financial embarrassment, but it necessarily aggravated the problem of securing sufficient tonnage, which had now to transport not only Allied supplies but American supplies and troops. In consequence, the supply departments found that their freedom to purchase when and where they wished, was, in spite of greater financial ease, more and not less restricted. Shipping was more and more concentrated in the North Atlantic, partly as an economy in its use which to some extent offset the greater demand upon it, and partly the more effectively to combat the submarine menace. The very fact that the United States was a belligerent and that the financing of supplies bought in North America was no longer a major preoccupation permitted the concentration. It thus came about that shipping considerations exercised at this stage of the war a much more effective control over purchasing programmes than the question of finance. Such further control as was possible in reinforcement of Treasury control was provided by the various Allied programme committees which were gradually constituted to deal with government demands for certain commodities, and as the circle of government trading was constantly enlarged these commodities came to cover a very large part of the field of Allied expenditure abroad.

(A. McF.)

INTERAMNA LIRENAS, an ancient town of Italy in the Volscian territory near the modern Pignataro Interamna, 5 m. S.E. of Aquinum; the additional name distinguishes it from Interamna Praetuttianorum (mod. Teramo) and Interamna Nahartium (mod. Terni). It was founded by the Romans as a Latin colony in 312 B.C. as a military base in the war against Samnium, no fewer than 4,000 colonists being sent thither. The city lay on a hill on the northern bank of the Liris, between two of its tributaries, thus lacking natural defences on the north side alone.

INTERBOROUGH RAPID TRANSIT COMPANY was incorporated in 1902 to operate rapid transit lines in the City of New York. Its capitalization consisted of \$35,000,000, in common stock. It acquired by assignment the lease of the original so-called subway of the City of New York, which was opened on Oct. 27, 1904, for a distance of twelve miles. On Jan. 1, 1903, it leased (effective April 1, 1903) the elevated railroad lines in the Boroughs of Manhattan and The Bronx, City of New York, from the Manhattan Railway Company, for a period of 999 years.

The company in 1928 operated, under lease from the City of New York, 75.26 route miles of municipally owned rapid transit lines, designated as the Subway division, and 41.39 route miles of privately owned elevated railroad lines, designated as the Manhattan division. During the first full fiscal year of operation the company carried 137,919,632 passengers on the Subway division, and during the same year carried 257,796,754 passengers on the Manhattan division. During the year ended June 30, 1928, it carried 899,238,749 passengers on the Subway division and 349,698,134 passengers on the Manhattan division. Its present outstanding capital stock, bonds and other obligations aggregate approximately \$247,600,000.

(F. HED.)

INTERCALARY (Lat. *intercalare*, to proclaim), a term applied to a month, day or days inserted between other months or days in order to adjust the reckoning of time, to the revolution of the earth round the sun, the solar year (see *CALENDAR*). From the meaning, "something placed between," intercalary is used for something which comes between two types. In botany, the term is used of growth between the apex and base of an organ, such

as the growth in length of an iris leaf, or of the internode of a grass-haulm.

INTERCOLUMNIATION, in architecture, the distance between the columns of a colonnade; usually defined by the number of times in which the bottom diameter of the column is included in the distance between the two closest points on adjacent columns. Thus the distance between the centre lines of two columns is one diameter more than their intercolumniation. The intercolumniation of classic columns was systematized at an early date and the following standard intercolumniations have been listed by Vitruvius and others: (a) pycnostyle, equal to one and a half diameters; (b) systyle, 2 diameters; (c) eustyle, 2 and a quarter diameters, so-called "well-columned," as the one most generally satisfactory; (d) diastyle, 3 diameters; (e) areostyle, 4 diameters; and (f) areosystyle, a complex form in which the columns are arranged in pairs with the distance between the pairs greater than the distance between the columns of each pair, as in the colonnade of the Louvre, Paris (by Claude Perrault, 1665). No such absolute standardization of intercolumniation as Vitruvius' list would suggest exists in classical work; frequently all the intercolumniations of a single colonnade differed, with the widest in the centre. The list must therefore be considered, like the so-called rules for the orders, merely as a summary of the averages.

INTERDICT, in its technical sense as an ecclesiastical term, is a sentence by a competent ecclesiastical authority forbidding all celebration of public worship, the administration of some sacraments (baptism, confirmation and penance are permitted) and ecclesiastical burial. An interdict is a measure which seeks to punish a population or a religious body (e.g., a chapter) for the fault of some only of its members, who cannot be reached separately. It is a penalty directed against society rather than against individuals. In the *Chronicle* of Ademar of Limoges (*ad ann.* 994) it is stated that Bishop Alduin introduced there "a new plan for punishing the wickedness of his people; he ordered the churches and monasteries to cease from divine worship and the people to abstain from divine praise, and thus he called excommunication" (see Gieseler, *Kirchengesch.* iii. 342, where also the text is given of a proposal to a similar effect made by Odoric, abbot of St. Martial, at the council of Limoges in 1031). It was not until the 11th century that the use of the interdict obtained a recognized place among the means of discipline at the disposal of the Roman hierarchy, which used it, without great success, to bring back the secular authorities to obedience. Important historical instances of the use of the interdict occur in the cases of Scotland under Pope Alexander III. in 1181, of France under Innocent III. in 1200 and of England under the same pope in 1209.

See A. Boudinhon, art. "Interdict" in the *Catholic Encyclopaedia*.

INTERDICTION, in Scots law, a process of restraint applied to prodigals and others who, "from weakness, facility or profusion, are liable to imposition." Its only effect is to prevent the person interdicted from effectively alienating his heritable or real property without the consent of his interdictors. It leaves him competent to dispose of his moveables. Interdiction is either voluntary or judicial. Voluntary interdiction is effected by the prodigal himself, who executes a bond obliging himself to do no deed which may affect his estate without the assent of certain persons called the "interdictors." This may be removed by the court of session, or by the joint act of the interdictors and the interdicted, or by the number of interdictors being reduced below the number constituting a quorum. Judicial interdiction is imposed by order of the court, either moved by an interested party or acting in the exercise of its *nobile officium*, and can only be removed by a similar order. That the interdiction may be effective in questions with third parties it must be published in the appropriate registers.

INTERESSE TERMINI, in law, an executory interest, being the right of entry which the grant of lease confers upon a lessee. Actual entry on the lands by the lessee converts the right into an estate. If the lease, however, has been created by a bargain and sale, which still exist in some colonies, or by any other conveyance under the English Statute of Uses, not requiring an entry, the term vests in the lessee at once. This doctrine

was abolished by the Law of Property Act, 1925, S. 149.

INTERFERENCE is the confusion of radio reception due to stray electrical disturbances, undesired signals or other causes. The name interference is also applied to that which produces the confusion.

INTERFERENCE OF LIGHT: *see* LIGHT and INTERFEROMETER.

INTERFEROMETER. An instrument which makes use of the interference of light waves (*see* LIGHT) to measure very small differences in length or very small differences in wave-length. On the one hand, if very homogeneous light (*i.e.*, light which covers an extremely small range of wave-length, often referred to as light of one wave-length) is used, a difference of optical path can be measured by the help of the interference fringes formed: on the other hand, if the light contains two or more separate, but very near, wave-lengths, the component wave lengths can be detected, and their separation measured, by the separation of the fringe systems. (*See* SPECTROSCOPY.) The interferometer has assumed great importance in modern physics, firstly from its use in attempts to measure a difference of optical path due to motion through a hypothetical ether, in experiments of the type initiated by Michelson and Morley (*see* ETHER, RELATIVITY), secondly from its use in the determination of the ultimate standard of length, that is, in measuring the length of the standard metre in terms of wave-lengths of a standard light (*see* SPECTROSCOPY), and thirdly from its use in resolving very close spectral lines, to which reference has just been made.

Separation of Interfering Beams.—The interferometer of Fabry and Perot, in which the interference is produced by repeated reflection of the light between two accurately plane glass plates, is described in the article LIGHT, where reference is also made to another multiple reflection interferometer, the Lummer plate. In both these instruments the reflections lead to what is virtually a large number of sources, with a large path difference, amounting to some tens of thousands of wave lengths, between successive beams. In contrast to such instruments, where the interference is due to the combined effect of a large number of beams produced by the reflections, are instruments in which two beams only, between which interference takes place, are produced from the original beam, the two beams following widely separated paths, so that, for instance, obstacles can be placed in one beam and their retarding effects measured by the consequent displacement of the interference fringes. In the instrument of Jamin the separation is effected by the use of thick plates, the interference from which was first investigated by Brewster. Two similar thick glass plates, with accurately parallel surfaces, are arranged as in fig. 1. The one of the two interfering beams is that which is reflected at the first surface of the first reflector

FIG. 1

and at the second surface of the second reflector: the other undergoes reflection at the second surface of the first reflector and at the first surface of the second reflector. If the plates are exactly parallel and exactly equal in thickness the two paths are equal and the two beams should leave the second plate exactly in phase; if there is any lack of parallelism or in homogeneity of the glass interference fringes will be seen. If any substance with a refractive index greater than that of air be introduced in the path of one beam only the retardation produced will cause a shift of the fringes, from which the refractive index can be calculated. To

enable the measurements to be made with greater ease a compensator is provided, consisting of two thin glass plates, one in each path, which can be independently tilted to make any desired angle with beam: the greater the inclination the greater the thickness of glass traversed by the beam, so that any desired retardation can be introduced. The instrument has been largely used to measure the refractive indices of gases, for which pur-

FIG. 2

pose glass-ended tubes are introduced into the path of the beams, one being evacuated, while the gas is slowly introduced into the other, the passage of the fringes being counted. Since the instrument was originally used for this purpose by Jamin it is often known as an interference refractometer. Extensive measurements of gaseous refractive indices have been made with it by C. Cuthbertson.

In the interferometer, also used for the accurate measurement of refractive indices of gases and weak solutions, devised by Lord Rayleigh (3rd Baron), light proceeding from a slit at A, fig. 2, perpendicular to the plane of the paper, falls upon a collimating lens B, which is blocked out by a screen except for two parallel slits at C and D. The parallel beams CE, DF transmitted by these slits are brought to a focus at G by the lens EF, and form interference bands in the focal plane. These bands, which are examined with a high power eye-piece, undergo displacement if any substance which causes relative retardation of the light is introduced into one of the paths. Consider, for example, what happens at the point G itself, which is the image of A. If everything is symmetrical so that the paths ACEG, ABFG are exactly equal, there is brightness, but if, for example, CE be subjected to a relative retardation amounting to half a wave length, we have darkness at G, the band being shifted through half a band interval.

The Michelson Interferometer.—The best known form of interferometer, and the one to which the designation was originally applied, is that devised by Michelson for the Michelson-Morley experiment (*see* ETHER, RELATIVITY, MICHELSON-MORLEY EXPERIMENT), on the effect of the motion of the luminiferous medium on the velocity of light. In this the interfering beams are not only widely separated, but travel, as is required by the experiment, at right angles to one another for the greater part of their path. Light from the source S, which may be an extended luminous surface (a candle, lamp or a lens with an arc light at the focus) falls at 45° on the surface of a plane-parallel glass plate (fig. 3), the surface of which is covered with a film of silver or platinum, of such thickness that the reflected and transmitted pencils are of approximately equal intensity. The transmitted beam falls normally on the mirror C, the reflected

FIG. 3

beam on the mirror C, the reflected beam on B, both returning to the separating surface A, whence they both proceed in the direction AE. Since the beam reflected from C has had to pass three times through the plate A, whereas the beam from B only passes once through A, a compensating plate P' similar to the plate A, is introduced, which is traversed twice by the beam which goes to B. The resulting interference fringes may be projected on a screen or observed by eye, with or without an observing telescope.

The construction of the instrument is indicated in fig. 4. A heavy casting serves to support the optical parts, and the car-

riage holding the movable mirror C moves on very accurately ground ways. The motion is communicated by means of a screw provided with a worm wheel and a divided circle so that the motion of the carriage may be accurately measured. The stationary mirror D is provided with screws for adjustments about vertical and horizontal axes. The compensating plate B is held by a vertical steel rod, twisting which produces any required small alteration in the path. All of the optical surfaces are very accurately plane, the errors being of the order of a twentieth of a light wave, or less.

The adjustment of the instrument is effected as follows. The distances of the mirrors C and B from the half-silvered surface of A are made approximately equal (say, to within a millimeter), and an approximately homogeneous source of light (sodium flame, or better, a Cooper-Hewitt mercury arc) is placed in front of A, as indicated by S. The two images of a needle point placed near S are then brought into coincidence by the adjusting screws of the mirror D, when the interference fringes should appear. They are usually narrow, curved, and not very distinct; but by slowly altering the adjustment of the mirror D they may be given any suitable width, and by diminishing the path difference by turning the screw S the fringes become more distinct. As the path difference approaches zero, the change of inclination of the fringes accompanying a change in position of the eye diminishes; and when this change vanishes, the (coloured) fringes in white light appear, or may be found in a few turns of the worm wheel which gives the slow motion to the screw S. The use of the instrument in the Michelson-Morley experiment is described under RELATIVITY, in measuring the standard metre in terms of lightwaves under SPECTROSCOPY.

THE THEORY OF THE INTERFEROMETER

The arrangement sketched in fig. 5A represents schematically the interferometer in its simplest form. B' represents the image of the mirror B in the mirror M, A and B' being supposed to be not quite coincident: it is evident that to the observer at E the effect of the whole combination is the same as that which would be produced by the surfaces A and B'. The light coming to E may then be considered as having come from two nearly coincident sources, which are the image of the source S in the two mirrors. These sources are therefore coherent, but not quite coincident, and the form and visibility of the fringes clearly depend upon the degree of coincidence of the two sources. Exact coincidence would be equivalent to a single source, and consequently there would be no fringes at all in such a case, but exact coincidence is not attained in practice, so that fringes are always visible. When the coincidence is nearly attained the fringes will clearly be broad; when the images are further apart the fringes will be narrow, and usually curved, as mentioned when the adjustment of the instrument was being discussed. The visibility will depend largely upon the aperture, since for good visibility the fringes formed by the two images of one part of the source should be superposed as nearly as possible on those formed by the two images of another part of the source.

As the moving mirror is displaced backwards the two images separate, and the fringes move across the field. Every time the

FIG. 4

FIG. 5A

distance between the images increases by a wave length a whole fringe moves past a given fixed point. If the light was perfectly homogeneous the fringes would be visible with any degree of separation of the images, that is, with any difference of path length between the two beams. If, however, the light is not perfectly monochromatic, then clearly with large enough path difference the fringes formed by one component of the light will cancel those formed by a neighbouring component. The fact that even with the most homogeneous source fringes never show with a path length greater than 70 cm. proves that the light consists of trains of about this length.

Michelson has discussed the formation of the fringes in the following way. In fig. 5B let AB be the two equivalent mirrors shown in fig. 5A, the intersection of their planes being vertical, and consider the effect of the reflection of light from a source R to a point O. Let t be the distance between the mirror surfaces at the point of incidence, ω be the angle of incidence, which may be considered the same for both mirrors, the angle ϕ between them being supposed to be very small (of the order of a second of arc, or less). Further let p be the perpendicular distance from O to the mirrors, t_0 the distance between the mirrors at the foot of this perpendicular, and i the angle between the horizontal projection of the incident ray and the normal. Then the difference in path of the two interfering pencils is seen to be expressed

$$\Delta = 2t \cos \omega$$

and

$$t = t_0 + p \tan i \tan \phi = t_0 + p i \phi$$

since ϕ is very small and so is i , the incidence being very nearly normal.

Hence

$$\Delta = 2(t_0 + p i \phi) \cos \omega$$

The corresponding phase difference is $2\pi \frac{\Delta}{\lambda}$, which with an unlimited aperture may clearly have so large a range of values that all traces of interference vanish. If, however, the cone of rays is limited, either by the pupil of the eye or, in the case of an observing telescope, by a diaphragm, then the range of angles may be small enough to show the phenomenon of interference.

Let us now enquire as to the distance p at which the fringes will be most clearly visible. This must occur when there is no change of Δ with ω , the angle of incidence, that is, when

$$\frac{d\Delta}{d\omega} = 0.$$

$$\text{Now } \frac{d\Delta}{d\omega} = -2 \sin \omega (t_0 + p i \phi) + 2 \cos \omega p \phi \frac{di}{d\omega} = 0, \text{ or since } \omega, i$$

and ϕ are all small, which leads to $\frac{di}{d\omega} = \frac{\omega}{i}$, we have

$$\omega (t_0 + p i \phi) = p \phi \frac{\omega}{i}$$

or

$$p = \frac{i t_0}{\phi}.$$

It follows that for an unlimited beam, when i has various values, the different parts of the interference paths are not simultaneously in focus except, firstly, if $t_0 = 0$, when $p = 0$ and the fringes are localised at the surfaces of the mirrors AB, or, secondly, if $\phi = 0$ or the mirrors are parallel, when $p = \infty$ and the fringes are localised at infinity.

If we call Δ_0 the phase difference for normal incidence, $\omega = 0$ and if $\Delta_0 - \Delta = n\lambda$, then

$$2t_0(1 - \cos \omega) - 2p i \phi \cos \omega = n\lambda$$

or, ω being small,

$$t_0 \omega^2 - 2p i \phi = n\lambda.$$

FIG. 5B

Let θ be the angle between the normal and the projection of the ray on the vertical plane containing the normal, and put

$$\frac{n\lambda}{t_0} = \rho^2, \quad \frac{p\phi}{t_0} = h.$$

Then

$$\omega^2 = i^2 + \theta^2 = \rho^2 + 2hi.$$

This represents a circle whose angular semidiameter is

$$\sqrt{\left(\frac{n\lambda}{t_0} + \frac{p^2}{t_0^2}\right)}$$

and whose centre is displaced through an angle $h = \frac{p\phi}{t_0}$, and so we see fringes which are circular arcs. If the separation t_0 is small, the equation reduces to

$n\lambda = -2p\phi i = 2\phi x$ where $x = -pi$ is the horizontal separation between the fringes, which is constant. Disregarding sign,

$x = \frac{n\lambda}{2\phi}$. The fringes are straight, and parallel to the intersection of the mirrors A, B'. The distance between consecutive fringes is clearly

$$b = \frac{x}{n} = \frac{\lambda}{2\phi}.$$

The visibility V of the fringes is defined by Michelson as

$$V = \frac{I_1 - I_2}{I_1 + I_2}$$

where I_1 and I_2 are the maximum and minimum intensities respectively. Michelson has shown that we can deduce the formula

$$V = \frac{\sin k p \phi (i_2 - i_1)}{k p \phi (i_2 - i_1)} \quad \text{where } k = 2\pi/\lambda$$

and i_1, i_2 are the limiting values of i for the incident beam. This shows that if $p=0$, which, as we have already seen, involves $t=0$ if all parts of the interference patterns are to be simultaneously in focus, then $V=1$, which is independent of the aperture. For moderate aperture the visibility is independent of the aperture. This is also true if $\phi=0$.

An idea of the order of magnitude of the angular aperture permissible may be obtained in an elementary way as follows. If the differences in phase between the central and marginal rays be λ the discordances will be considerable. In the case where $\phi=0$, and the mirrors are truly parallel, if β is the angular aperture of the objective, then

$$\text{difference in phase} = 2t(1 - \cos \beta/2) = \lambda$$

whence $\beta^2 = \lambda/t$ as a first approximation. Thus if $t = 25\lambda$, then $\beta = \frac{1}{5}$, and the angular aperture of the lens should certainly be less than $\frac{1}{5}$.

Comparative Place of Interferometer as an Optical Instrument.—It had been pointed out by Michelson that the interferometer can be regarded as a modification of the ordinary instrument, telescope or microscope, consisting of lenses or mirrors, and that prisms and gratings as well have their analogies in interferometers. We will consider first the case of a converging lens, of supposedly perfect optical construction, that is, for which the optical distance from point to point is equal for all paths. Such a lens, considered as an optical instrument, may be employed to form an accurate image of the object, as in an astronomical observing telescope, but it may also be used for accurate measurement of a displacement, or angle, where a representation of the object is not necessary, so long as there is some recognizable feature of the image on which a setting can be made. It is well known that the image of a luminous point formed by a lens is a diffraction pattern consisting of a bright spot, surrounded by rings, and that the resolving power of the instrument depends upon the extent of the overlapping of the diffraction rings due to two close object-points. (See LIGHT, section on Resolving Power.) The size of the diffraction pattern is inversely proportional to the angular aperture of the lens, and the definition and the re-

solving power both increase as this aperture is increased. With a given aperture, however, the indistinctness of the image becomes more and more pronounced with increasing magnification, since all the imperfections of the image are subject to the same enlargement as the size itself, while the brightness diminishes. The interference fringes of the diffraction pattern, however, are more accurately measurable if the pattern is magnified, since, generally speaking, setting a cross-wire is possible to within a fixed fraction of the fringe width.

FIG. 6

solving power both increase as this aperture is increased. With a given aperture, however, the indistinctness of the image becomes more and more pronounced with increasing magnification, since all the imperfections of the image are subject to the same enlargement as the size itself, while the brightness diminishes. The interference fringes of the diffraction pattern, however, are more accurately measurable if the pattern is magnified, since, generally speaking, setting a cross-wire is possible to within a fixed fraction of the fringe width.

For the purpose of accurate measurement of position or angle we may therefore block out the central portion of the lens altogether, leaving merely a circular annulus which will produce sharp rings, or, better still, we can merely isolate two small portions of the lens at opposite ends of a diameter. We shall in this way obtain an exceedingly bad image of the luminous object, but we shall have interference fringes which can be increased in size up to practically any limit without affecting the amount of light. The result is exactly the same, as far as measuring position is concerned, as could be obtained with a perfect microscope of infinitely great magnifying power with an infinitely bright source. This device of isolating two small strips of lens at the opposite end of a diameter is, in fact, that adopted in Rayleigh's interferometer, already described. Regarding the lens as an optical instrument we sacrifice resolution and definition, with a gain of accuracy of measurement. We may then say that, since all optical phenomena ultimately depend upon interference in its most general conception, there is no fundamental difference between the interferometer and ordinary lens system. The analogies will now be considered in a little more detail.

The Rayleigh interferometer has already been considered. The close analogy between the optically perfect convex lens and an interferometer consisting of four mirrors is illustrated in fig. 6.

FIG. 7

Thus in fig. 6A the image of a source (a slit A, or a fine line ruled by a diamond on a smooth glass or metal surface) is formed at D (the result of the "combination" of all the rays which fall on the lens BC), where it may be observed, as in the telescope or the microscope, by an eyepiece.

In fig. 6B the source is replaced by the surface A, whence two of the pencils (one transmitted and the other reflected) are bent by the prisms (or mirrors) at B and C so that they meet at the surface D, proceeding thence to the eye or the observing telescope. In fig. 7 the same analogy is illustrated when the lens is replaced by a mirror.

Thus it appears that the essential difference between lenses or mirrors, on the one hand, and the interferometer, on the other, is that in the former all the rays from the source which fall on the lens unite in the focal plane to form an image; whereas in the interferometer of the type in question there are only two interfering pencils. The advantage of this has already been

pointed out. In the illustrations just given, the microscope or telescope, and the analogous forms of interferometers, may be applied to the measurement of distances or of angles.

But prisms and gratings are employed in what seems at first sight to involve different principles, and for a different purpose, namely, the analysis of light into its component constituents. The analogy still holds, however, as is shown in fig. 8A and B. Thus in figure 8A, *A* represents the slit source of light and *BC* a grating which diffracts the light back to *A* (part being thrown on one side by the plane-parallel plate *P* for observation or for photography) while in figures 8B and 8C, the interferometer shows a similar light-path, but only for the two limiting pencils of light, 8C being produced from 8B by a slight rearrangement of the mirrors.

If in this arrangement one of the mirrors, say *C*, is movable, and the incident light monochromatic of wave-length and if *n* is the number of maxima (or minima) corresponding to *d*, the measured difference in path, then the wave-length is given by $\lambda = d/n$; and, as is described under *Spectroscopy*, this can be measured with far greater accuracy than is possible by the use of prisms or gratings.

Any arrangement of mirrors and lenses has its analogue in a possible interferometer. Fig. 9 shows three different dispositions of optical apparatus and three corresponding interferometers. The diagrams are self-explanatory, *A* being a concave mirror with the source at the centre of curvature, and hence a single plane mirror in place of the two mirrors of fig. 7; *C* a double convex lens with equidistant object and image, a variation on fig. 6; and *B* a concave mirror and two plane mirrors with the source at the focus of the mirror. The interferometer diagrammatically represented in Ciii. is a slight variation on that of Cii. obtained if the mirrors *B* and *C* are separated until *AB* and *AC* are at right angles.

Measurement of the Standard Metre in Terms of Light Waves.

The standard metre is defined as the distance between two fine lines on a particular iridio-platinum bar kept at Paris. It is, however, clearly desirable to have some absolute standard of length, not depending upon a particular piece of material, since not only are secular changes possible in the material which will produce minute changes in length, but also, in the remote chance of an accident to the bar, it should be possible to replace it. Long ago two proposals were made to fill this need, the first being to adopt as a standard the length of a pendulum which swings once a second at Paris. It was found on trial that the error of measurement was considerably greater than expected. The second proposal was to use the earth's circumference as a standard, and, in fact, the original metre was intended to be one forty-millionth of this length. As a result of several of the very costly investigations of the measurement of a given arc of the meridian it proved, however, that this measurement was too inaccurate to serve. The interferometer with large

differences of light paths enables us to measure a length of many centimetres in terms of the wave length of a specified light, and so gives us a standard which can be easily reproduced at any time or place. The International Committee on Weights and Measures decided, in fact, in 1923 on the adoption of such a standard, so that the measurement of the standard metre in terms of a wave length is of the highest importance.

If a wave length is to be a standard length it is, of course, essential that the light should be very homogeneous; among the hundreds of radiations examined none answered the requirements so well as the red line of cadmium vapour. With this light interference fringes are still measurable with a path difference of 22 cm., which distance contains about 350,000 waves, or, say, 700,000 fringes. The optical error of measurement will depend somewhat on the visibility of the fringes, but an estimate of one-tenth of a fringe width is quite conservative, and thus indicates the possibility of making such a measurement to an order of accuracy of one in ten million. The general principle of the method is simply to move the mirror of the interferometer through a distance given by the standard, and to count the number of fringes, but to make sure that the mirror has actually been moved through the standard distance, and to extend the measurements to a length of a metre a number of special devices are necessary.

Since fringes cannot be obtained with a path difference of one metre, and even distances of several centimetres are troublesome, as they involve the counting of some hundred thousand fringes, a standard decimetre and a series of substandards were prepared. The standard decimetre was afterwards compared with the metre in a way which will be described. The intermediate standards, by the help of which the number of fringes was reduced to a countable one, consisted of a 5 cm. one, a 2.5 cm. one, and so on, each successive standard being half the length of the previous one, the ninth and last being .39 mm., which contains only 600 red light waves, or 1,200 fringes in the doubled distance between the parallel surfaces which constitute the standard. This number of fringes can readily be counted without fear of error. The construction of those intermediate standards is made clear by the example shown in fig. 10. It consists of two plane-parallel glasses *A*, *A* shown on the front surfaces, and held in contact with three brass pins, which are filed and polished until the two surfaces are as nearly parallel as required. The distance between the planes of the front surfaces of these mirrors, one of which stands, as will be seen, higher than the other, constitutes the standard length.

The first task is to determine the exact number of wave lengths in the smallest standard, which we will call standard I. Fig. 11 represents the interferometer set up for this purpose: *d* is the moveable mirror, *m m'* are the two mirrors of the standard (the distance between them being exaggerated in the diagram) and *n* is a stationary auxiliary mirror. This mirror is used for the purpose of counting the fringes that pass when *d* is displaced, that is, for measuring the displacement of *d* in wave lengths. To start, the front surface of *m* is made to fall in line with the image of the reference plane *d*, making, however, a very small horizontal angle with it, so that with white light a series of vertical interference bands is formed, the central band being achromatic and therefore readily distinguishable. The mirror *d* is now steadily moved back, and the succession of circular fringes formed by the cadmium light on *n* is counted. The

FIG. 9A

FIG. 9B

FIG. 9C

FIG. 10

FIG. 11

motion is continued until d coincides with the rear surface m' , a coincidence detected once more by the white light fringes, the achromatic band being brought to the same position on m' as it had before on m . The motion of d is thus measured in terms of wave lengths of cadmium light, and the limits of its motion, given by the distance between m and m' , determined by the use of white light fringes to establish coincidence.

The next step is to compare standard II. with the one already measured. Now n represents the front mirror of standard II., n' the rear mirror. The two mirrors m and n are brought into the same plane with the help of white light fringes. The mirror d is now moved to coincide with m' , and standard I. is moved until fringes reappear on m , so that m' and n' are now very nearly in the same plane. The small distance between m' and n' in this position is determined in fractions of a fringe of cadmium light by moving d , so that the correction to be applied to standard II. is determined. Standard III. is checked against II. in the same way, and so on, until the decimetre is reached.

The table gives the results of three independent measurements of the number of light waves in the (doubled) length of standard IX., the decimetre. The fact that these measurements were made, at different times, months apart, and by different individuals, and still give the same result to a few hundredths of a light wave, gives confidence in the accuracy of the result. Besides the red line of cadmium, the green and the blue line were used, as recorded.

Series	Red	Green	Blue
I.	310,678.48	393,307.92	416,735.86
II.	310,678.65	393,308.10	416,736.07
III.	310,678.68	393,308.09	416,736.02

The final operation is the comparison of the decimetre with the standard metre. For this purpose an auxiliary metre X. was provided with two diamond scratches at a distance apart very nearly equal to a metre. An arm extending at right angles from the decimetre has a similar mark which is placed as nearly as possible in coincidence with one of the metre marks. The standard decimetre is then "stepped off" ten times by the help of the interferometer fringes. The resulting error is, however, multiplied by ten, instead of by two as in the comparison of the smaller standards. It is estimated that the error of separate determinations of the metre may be of the order of one-half of a light wave, but the mean of all measurements is doubtless much less. To this error must, however, be added the errors of the micrometric measurements of the "coincidences" at both ends of the metre bar, and finally the error of the comparison of the auxiliary metre with the standard.

The final results are as follows:

Number of Light Waves of the Three Principal Cadmium Radiations in the Standard Metre

Red	1,553,163.5
Green	1,966,249.7
Blue	2,083,372.1

The metre rod is in air at 15° C and 760 mm. of mercury pressure. It is estimated that these results are correct to about one part in two million.

Measurement of Stellar Diameters.—Most of the applications of the interferometer have been mentioned at one part or another of this article. The chief of them are:—the measurement of standard wave length, or, differently put, the measurement of the meter in terms of the light wave; the measurement of the maximum distance over which interference can be produced, or the coherence of a wave train: the measurement of refractive indices of gases and weak solutions: and the resolution of close spectral lines. Reference must also be made to the recent application of interferometric methods for the measurement of stellar diameters. Suppose we consider the whole of the lens of a telescope stopped out, except for two slits at opposite ends of a diameter, as in the Rayleigh interferometer. A single luminous point will produce a pattern of interference fringes. A second

close luminous point will likewise produce a pattern of fringes overlapping the first pattern. If we consider the two points as originally coincident, and then gradually separate them, the superposed pattern will give a certain pattern of fluctuating intensities depending upon the separation, but ultimately a separation will be reached such that the darkest parts of one pattern fall exactly upon the brightest parts of the other pattern, and we shall have uniform illumination. The argument can be extended to an uniformly illuminated disc, for which it can be proved that the fringes vanish when

$$\alpha = \frac{1.22\lambda}{S}$$

where S is the separation of the two slits, λ the wave length of the light used, and α the angle subtended at the telescope by the diameter of the disc.

This principle has been applied by Michelson to the measurement of stellar diameters. It is not feasible to make a lens of

FIG. 12

large enough diameter to hope for vanishing with the extremely small α provided by a star disc, but Michelson gets over the difficulty by receiving the light from the star on two mirrors set at 45°, from which it passes to two other 45° mirrors which throw the light in two pencils at opposite ends of a diameter of the lens or the mirror of the telescope. The general arrangement of the mirrors on the great reflecting telescope at Mount Wilson is shown in fig. 12. The separation of the first two mirrors, which, with the second two, are mounted on an arm set normally across the telescope at the aperture and, is limited only by mechanical considerations, and, in Michelson's first instrument, was variable and could be made as great as 20 ft. The method of mounting of the mirrors is indicated in fig. 13. With the red star Betelgeuse a vanishing of the fringes was obtained with a separation of about 10 feet (306 cm.), which, taking the effective λ as 5.75×10^{-5} cm., gives the angular diameter α to be .047 seconds of arc. Using a parallax of .018 we obtain an estimate of 240 million miles for the linear diameter of this star. The diameters of a few other stars have been measured by this method. In 1928 an

FIG. 13

interferometer of the pattern in question is under construction at Mount Wilson which will allow a 50 foot separation of the mirrors. (See STAR.)

BIBLIOGRAPHY.—The principles of interferometers are described in the standard text-books on Optics, cited in the bibliography to Light, to which may be added Lummer's volume on Light in Müller-Pouillet's *Handbuch der Physik*. A general account of Michelson's work is given in Michelson's *Light Waves and their Uses and Studies in Optics*. The analogy between interferometers and other optical instruments was first pointed out by Michelson in the American Journal of Science 39, 115, 1890. (A. A. M.; E. N. DA C. A.)

INTERGLACIAL STAGES, a series of comparatively warm and mild intervals, each lasting several thousand years, between the equally prolonged times of extreme cold in the Pleistocene glacial period (*q.v.*). For the stages of extreme cold the geologist Albrecht Penck chose names from representative districts in the Alps: Günz, Mindel, Riss and Würm; of these, the Günz stage is the earliest, the Würm stage is the most recent. Penck chose these names because their order in

the alphabet corresponds to the chronological order of the four stages, while space is left between them for additional names, should additional stages of cold be defined.

The same names are conveniently used to indicate the intervening warmer stages. Thus the first mild interglacial stage is called the Günz-Mindel stage; the second, the Mindel-Riss stage; the third, the Riss-Würm. This cyclic alternation of climate through the Pleistocene period is accompanied by alternating Arctic and temperate fauna and flora, while there is a further change, particularly of the fauna, due to the steady evolution of forms throughout the Pleistocene period. Thus in Europe during the colder stages the woolly mammoth and reindeer reached the south of France, while one of the interglacial stages was so warm that the lion and hippopotamus flourished in England.

In North America there was a similar cyclic alternation of climatic conditions throughout the Pleistocene glacial period, but there are difficulties in the way of drawing definite parallels between the Old World and the American stages. It is likely, however, that the earliest glacial stage in North America, which includes the pre-Kansan, Nebraskan and Albertan drifts, and which is called sub-Aftonian by American geologists, coincided with the Günz of Penck. The earliest, or Aftonian, interglacial stage of North America would thus correspond with Penck's Günz-Mindel interval. In North America, the Aftonian interglacial stage was marked by the presence of mastodons, three species of elephants, six species of horses, and the sabre-toothed tiger.

The second, or Kansan glacial stage in North America, corresponding to the Mindel of Europe, saw the extinction of some American camels and horses. It was followed by the Yarmouth interglacial stage, parallel to Penck's Mindel-Riss, when the fauna included mastodons, mammoths, horses, tapirs, bison, deer and sabre-toothed tigers.

The third, or Illinoian, glacial stage in North America, corresponds to Penck's Riss. It was followed by the Sangamon interglacial stage; this was in its turn fourth, or Iowan, glacial stage, the record of which is not well defined. The fourth, or Peorian, interglacial stage followed; it presents similar difficulties.

The fifth, or Wisconsin, glacial stage appears to correspond to the European Würm. It was followed by the post-glacial stage, which gradually merges into the present time. Elephants, mastodons, horses and the great sloths disappeared, the exact cause of their disappearance being unknown.

In the earlier or pre-glacial stage, Pleistocene vegetation was characterized by a commingling of warm temperate and cool temperate forms. During the alternating interglacial periods the record of plant life in the more northern regions indicates a succession of forest, barren ground, steppe, tundra and arctic types with each increase of glaciation. Upon the retreat of the glaciers this succession of plant types recurred but in reversed order. In some interglacial periods the climate was milder for the same latitudes than at the present time, so that numerous trees, for example, extended some hundreds of miles north of their present range. In the post-glacial or late Pleistocene stage, which blends into the Recent, plant life assumed substantially the present status and distribution. Many arguments may be advanced supporting the view that the post-glacial and recent constitute a part of an interglacial stage, as the time that has elapsed since the disappearance of the last great ice-sheets from Europe and north-eastern North America is less than the duration of some of the former interglacial stages.

The effect of glaciation upon the vegetation of Europe and North America, especially the former, was profound, not only with reference to the present distribution of the flora, but also as regards the extinction of old and the evolution of new types. In Europe the high mountain chains, which extend in an east-and-west direction, together with the Mediterranean, Black and Caspian seas, prevented the migration of the flora southward. In consequence an immense number of plants formerly components of the European flora, particularly that north of the Alps, was obliterated by glaciation. Numerous types of trees now found only in North America and Asia were abundant in Europe in

pre-Pleistocene and part of Pleistocene times. Among these were such important trees as the black walnut, butternut, hickory, magnolia, bald cypress and sassafras (*qq.v.*).

In North America the back-and-forth movement of plant life was not impeded, as in Europe, by high mountains and inland seas. The presence of the larch (*Larix laricina*) in Georgia, of the black spruce (*Picea mariana*) in Kansas and of the white spruce (*Picea glauca*) in Iowa, all far south of their present range, has been demonstrated. Likewise, the presence during a mild interglacial stage of a fig in fruit in British Columbia, and of the redbud (*Cercis*), the Osage orange (*Maclura*), the papaw (*Asimina triloba*) and other warm temperate types as far north as Toronto, Ont., has been proved.

INTERIM (Lat. *interim*, in the meantime), a word specially applied to certain edicts passed by imperial diets during the reformation in Germany with the object of *temporarily* settling controversial points of doctrine and ecclesiastical practice until they could be decided finally by a general council. The interim of Regensburg (Ratisbon) was promulgated in 1541; but the most famous example of such a *modus vivendi* was the interim of Augsburg (1548). This, drawn up at the bidding of Charles V. by Michael Helding, Julius von Pflug and Johannes Agricola, who represented orthodox catholic, Erasmian, and moderate Lutheran opinions respectively, was an ambiguous compromise, accepting on the one hand transubstantiation, the seven sacraments, adoration of the Virgin and saints, and papal headship, but admitting on the other justification by faith, marriage of priests, and lay communion in both kinds. The variation permitted to Maurice of Saxony within his dominions was called the Leipzig interim, and was signed on Dec. 22, 1548.

INTERIOR DECORATION, the art of furnishing and decorating the interior of a building, generally a residence. Furniture, rugs, lamps, wall-coverings, curtains, wall paper, as well as fixtures, bric-a-brac, etc. are the principal materials involved in the art of interior decoration. This article will treat historically the various styles of furniture, etc., under the following heads: EUROPEAN; EARLY ENGLISH; EARLY AMERICAN; CHINESE; JAPANESE; MODERN WOOD FINISHES, PAINTS AND VARNISHES.

EUROPEAN

Early Middle Ages.—In the earliest middle ages domestic life, such as we understand it, can hardly be said to have existed at all. Furniture and equipments had to be of a kind convenient for transport from one place to another. They were solid and strong, and in number they were kept down to the indispensable minimum. Military equipment formed a large part of the travelling baggage. There was no question of a separate furnishing of each temporary abode. Above all, it was necessary for the owner to be able to hold what he had. His habitation was rather a stronghold than a dwelling-house. The principal living apartment was a large hall with bare walls, open-beamed roof, narrow windows (probably unglazed) and floor paved with stone slabs or tiles. It contained very few pieces of furniture, and mostly such as could be brought by the occupants and carried away again when they went elsewhere. Window curtains, if used, were strung on hinged rods swung away from the window in day-time. The doorway might have some similar contrivance. A large hooded chimney maintained a log fire. Metal braziers on wheels, for local heating, were added during the later middle ages. Warming-pans were probably a still later innovation. A massive table would be fixed to the floor at one end of the hall. Upon it entertainers would mount, to divert the company between or after the courses. Long trestle-tables, easily movable for dancing or displays, were in general use. The seats were mostly plain benches or stools without backs. If a fixed bench ran along one of the walls, there might be panelling at the back against the coldness of the stone behind, and a cushion or two. There were a few folding chairs, generally of metal, light and easily portable, and perhaps a chair of state. Sitting upon the floor, on cushions or rugs, was long customary. The coffer with hinged lid was the chief provision for storage. It served as a packing case during transit, and afterwards as a general repository. It also formed a supplementary bench or table. There was a

EUROPEAN FURNITURE AND INTERIORS OF THE MIDDLE AGES AND RENAISSANCE

1. Room in the Royal Palace, Palermo, Sicily, known as the apartment of King Roger II.; an interior of the Norman period (12th century) showing the influence of the earlier Saracen rulers of the island. The room, though small, has an effect of great splendour. The walls are lined with marble, with animals, birds and trees above in gold and coloured mosaics
2. "King René seated at table," from an illuminated manuscript at Chantilly, showing a French interior of the first half of the 15th century. The wall is decorated with tapestry, and rush matting covers the floor. A screen of rushes is placed between the king's seat and the fireplace behind it
3. German oak cupboard with Gothic tracery, iron locks and hinges, 15th century
4. Spanish sideboard carved with Gothic tracery, 15th century
5. Bedroom with walls and ceiling of wood, from the Landesfürstliche Burg at Meran, South Tirol. A Tirolese interior of the 15th century
6. Room from the Speisshof, Switzerland, about 1580, re-erected in the Historical Museum at Basle
7. Room from the "House of the Cardinal," 1540, re-erected in the Historical Museum at Basle. A chandelier hangs from the rafters and on the left is a table with the hinged top open, revealing the space used for storing writing implements or toilet articles
8. Room with wood floor and carved and panelled walls and ceiling, from a house in Flims, Switzerland, 17th century
9. Courtyard entrance of the castle of Issogne, Val d'Aosta, north Italy; wall bench, linen-fold panelling, and frescoes below the vaulting, 15th century
10. Kitchen of the Castle of Issogne, Val d'Aosta; the floor is paved with stone, and the ceiling is vaulted

EUROPEAN FURNITURE AND INTERIORS OF THE 17TH TO THE 19TH CENTURY

1. Venetian chair of carved walnut upholstered in velvet. 17th century.
2. Dutch ebony cabinet on ebony stand. The doors and drawer fronts are carved with mythological and other subjects and edged with wavy mouldings. The architectural ornament of the interior is inlaid ivory and coloured woods. Middle of the 17th century
3. French ebony cabinet with marquetry of tortoise shell and brass, marble top and gilt bronze mounting. Probably after a design by Berain. Late 17th or 18th century
4. "Bureau du Roi" made for Louis XV. of France by Oeben and Riesener between 1760 and 1769. It is made of marquetry of various woods and adorned with mouldings, statuettes, vases and gilt bronze plaques
5. French writing table in sycamore wood with gilt bronze mounts, marble top and inlay of plaques of Sèvres porcelain. Period of Louis XV.
6. Bedstead of carved and gilt wood with coverings of blue silk damask. French. Period of Louis XVI.
7. Panelled room of painted and gilded oak erected between 1682 and 1694 by Alexandre Sévin in the Château de la Tournerie near Alençon
8. Salle du Conseil at Fontainebleau, built under Charles IX. and decorated under Louis XIV. and Louis XV. The walls and ceilings are painted by F. Boucher and the settees and chairs covered with Beauvais tapestry
9. Boudoir (re-erected) constructed for Madame de Sérilly, lady-of-honour to Queen Marie Antoinette. Late 18th century
10. Commode with marquetry of coloured woods, marble top and gilt bronze mounts by J. Caffieri. From the room of Louis XV., Versailles
11. Interior of Herrenchiemsee castle, a magnificent building in Louis XIV. style erected on the Chiemsee, Bavaria, by Louis II., 1878-85

simple form of dresser, for the preparation of food, with shelves above for utensils.

One or more spaces in the hall were curtained off by movable hangings, suspended from the rafters or from iron rods projecting from the walls. Separate apartments were thus temporarily provided. Low movable beds were placed within, covered with blankets or skins. Mattresses and pillows were stuffed with peapods or straw; feathers did not come into general use before the 15th century. The wealthy also had travelling beds, of palanquin form, borne behind and before by horses or men. If recesses in the hall were curtained off, a nearer approach to separate sleeping-rooms was provided. The cabinets or bowers for women's work and recreation were formed in this way.

The kitchen was a low apartment with a depression in the middle of the floor for the fire, provided with a great iron grid, which was slid over for cooking upon. In some cases there were one or two private rooms, perhaps on an upper floor. Guests were accommodated in the large hall, where movable beds could be set up in case of need. Sometimes strangers had separate apartments, with an entrance from outside. In the greater houses there was a chapel, where daily prayers were read.

Later Middle Ages.—Such conditions, varied according to local circumstance, were generally prevalent in western Europe down to the close of the 12th century. Where Eastern habits of life had already penetrated, as in Sicily or Spain, magnificent buildings were erected. A room in the palace at Palermo, Sicily, is still known as that of the Norman king, Roger II. The walls are lined with marble, and the lunettes and ceiling above are encrusted with elaborate mosaics. Changes were gradual and progressive, but a definite step forward was made about the 12th century. Most of the military leaders in France (and many in neighbouring lands) had by then taken part in the Crusades, and they had learned something of a more luxurious mode of living. The accumulation of possessions now began, and women took a more prominent share in the regulation of the household and the provision of daily needs. Curtains brought from the East would be of thinner texture, and they were drawn back in folds rather than swung away from the windows. The better store of hangings enabled the bareness of the walls to be relieved. The wooden ceilings were coffered, and sometimes painted in bright colours and gold. Where folding shutters were provided for the windows, the need of glazing would be obviated. The high table was placed across the end of the hall, where the floor was raised. Long massive tables at right angles accommodated the household and retainers. Tables of horse-shoe form might still be used, as in early times, for convenience in serving. Tables for the dishes were at the lower end of the hall. A small "credence" table, for tasting wine and liquors, was set against a side wall. Wooden cradles for infants were made to rock on the floor, or to swing between end-supports. Seats with upright wood backs, and, perhaps, a carved hood above, would replace the plainer benches for the chief personages. The coffer, or chest with hinged lid—that perennial and indispensable article of furniture—had its drawbacks. Everything set upon it had to be removed before it could be opened. Hinged doors were therefore set in front, perhaps with a nest of drawers behind, and a long drawer below. From this the *armoire* and the varieties of presses and cupboards would take shape. Beds became fixtures, though not yet relegated to separate sleeping-rooms. They were of panelled wood, sometimes taking the form of a huge cupboard with open front. The mattress raised above the floor was often of ample dimensions, affording space for a whole family in case of need. It was generally set in the corner of the room, and at the free angle the curtain was looped up during the daytime in a kind of rolled bundle, still exemplified in Dutch pictures as late as the 17th century. Sometimes there was a narrow space between the bed and the wall for dressing and undressing. This was screened off by the bed-curtains.

In the later middle ages the wardrobe was a separate room, with deep presses lining the walls, having cupboards above and lockers below. Here were stored the hangings, floor-coverings, curtains, tapestries and linen of the establishment, besides the garments and materials for a large household. With the lack of shops this

was the place to replenish supplies. It was also the workroom of the establishment, with tables and other provision for tailors, repairers and neediewomen.

As the middle ages went forward, the hall continued to serve many purposes; but gradually the dwelling became divided into ante-chamber, hall and withdrawing-chamber. There might be also a state bedroom, where guests could be received. A *lit de parade* was sometimes provided solely for this purpose. The "bed of justice," of which we hear from mediaeval times onwards, was at first a couch or low seat for reclining upon, where the French sovereign met his parliament.

The kitchen was now provided with vast low arched recesses in the walls, where the fire could be better regulated than in the middle of the floor. Rotating spits, in stages, for roasting, had dripping pans below, and there were hooks for suspending cooking-pots over the fire.

The floor (of stone or earthenware tiles in large houses, of the bare earth in others) was covered with sawdust, as it is even to-day in great kitchens. In course of time it became usual to spread the floor with rushes and fragrant herbs. It was not till the later middle ages that the rushes were plaited into mats. Plain woollen cloth or furs were sometimes laid down. For ceremonial, rich stuffs were spread before the royal throne. Oriental pile carpets were not used before the 15th century, and they were rare in western Europe before the 17th century.

Torches at first provided the principal lighting, and the fire served to give light as well as heat. There might be a few sconces fixed to the walls, with prickets for candles. A small hanging lamp with floating wick was more convenient than the candle for the light, which was usually kept burning all night within the bed-curtains, as much to scare away spirits as corporeal beings. Standing candelabra of iron for many candles came into use, as well as small portable pricket candlesticks, and occasionally chandeliers or "lustres" hung from the rafters.

As the women of the household took more and more to the management of domestic affairs, furniture tended to accumulate. The use of ornaments and various articles of luxury grew during the times of the Crusades, increasing as commercial relations with the Near East became closer in subsequent centuries. Indoor provision for washing and bathing must also be included among luxuries. A long trough with a row of taps in a courtyard served for most of the household. At times there was a tank or cistern with water continually running. A metal bowl, flat-sided, was sometimes fixed to the wall of a living room, with a swinging ewer or a small cistern with tap over it, and a towel upon a hinged rod near by. Provision for reading was made by a portable lectern with sloping top. The top might revolve to facilitate reference to different books, or it would work up and down for convenience. Sometimes it had a recess for the storage of books. A sloping board for writing upon could be adjusted to the arms of a seat, or it could rest on a table. Sometimes a shallow box, with inkhole, was set on the writer's knees.

Small convex mirrors were hung to the walls as early as the 15th century, but hand mirrors of polished metal or glass were the only mirrors in general use before that time.

An illustration in the celebrated manuscript in the Museum at Chantilly, the "très riches Heures du Duc de Berri," represents King René seated at table. Behind him is a fire in a hooded chimney. He is protected from its heat by a circular screen of plaited rushes. The wall is covered by a tapestry hung upon hooks. Rush matting is on the floor. The table is covered with a white cloth, and courtiers and servants are busy around. It forms a striking picture of seigniorial life in the first half of the 15th century.

A German oak cupboard of the 15th century, carved with Gothic tracery and provided with iron hinges, is here shown in Pl. I., fig. 3. An oak sideboard, from Spain, is also reproduced. (Pl. I., fig. 4.)

The amount of mediaeval domestic furniture which has come down to the present day is relatively small, but the general characteristics need to be borne in mind, for the middle ages were the cradle of later times, and much that came afterwards is explained by reference to them. Indeed, in backward countries, or in remote districts little affected by change of fashion, the

mediaeval tradition has been carried down to our own times. Besides eastern Europe, parts of Switzerland and Scandinavia may be cited as examples. The wooden chair (*see* WOODCARVING), from Tyldalen church, in Oesterdalen, Norway, is attributed to the 18th century.

Alpine Lands.—The mediaeval furniture of the lowlands was principally of oak and hard woods, but in mountainous districts, such as Switzerland, the Tyrol and south Germany, the use of fir, pine and the softer woods at hand determined the form and ornamentation of the furniture made from them. Such woods were often the only available building materials as well, and floor, walls and ceiling alike would be entirely of wood, as they often are to-day. The bedroom from the Landesfürstliche Burg at Meran, South Tyrol (Pl. I., fig. 5) is a remarkably complete and well-preserved example of an interior in a house of some standing in the latter half of the 15th century. The old Swiss furnished interiors shown in Pl. I., fig. 6, though only in one case dating back to the mediaeval period, illustrate much that has been said about earlier times. Most of them belong to a series in the Historical museum at Basle, carefully removed from old houses, chiefly in the town. There are others in the museums of Berne and Zurich, covering the period from the 15th to the 17th century. Floors are of wood, walls and ceilings are moulded and panelled. Sometimes there is inlay or veneering of harder and more ornamental woods. The mouldings are bold, but any carving is usually in slight relief, owing to the nature of the wood, and the inlay is generally simple and geometrical. Tables have legs of trestle form, and the tops are hinged so as to lift up and reveal a spacious receptacle for writing implements or articles of the toilet. Chairs are primitive, with solid wooden seats and splayed legs. Benches are fitted along the wall. Panelled beds of ample size are in the living-room. Coffers tend to be high, with a wider base containing one or two drawers. The walls being of wood, the construction of corner cupboards is simple. Flat carving may be in a style recalling fretwork. Bands of foliage and other ornament following the Gothic tradition, and suited to the coarse grain and softness of the wood, are very effective. These decorative parts were painted in bright colours, and entire pieces of furniture were sometimes painted over with figure-ornament or other motives.

Italy.—The Castello d'Issogne, in the Val d'Aosta, in northern Italy, is remarkable among surviving examples of the adaptation of the mediaeval domestic interior to the mild climate south of the Alps. It was built about the year 1490 by a member of the Challant family, who held the post of governor of the Val d'Aosta. Though mediaeval in structure and appearance, it is not a stronghold, but a summer retreat. It is built in a square with a tower at each corner. There is an inner courtyard, along one side of which is a kind of vaulted portico supported by pillars and open to the courtyard. This is used as a hall, with wooden linen-fold panelling and a fixed bench running along the wall. The lunettes above the panelling are filled with fresco paintings of scenes in daily life—the shops of a provision merchant, an apothecary, and a tailor and draper, an outdoor market, and soldiers in a guard-room. There is also a dining-room with credence, tables and stools, an armoury, a kitchen, servants' hall and chapel. The coffered ceilings are carved and painted (*see* Plate I., figs. 9 and 10).

During the middle ages furniture in Italy differed but little from that of neighbouring countries. Any deviation was likely to be due to the use of walnut, a more tractable wood than oak, and to the outdoor life which rendered an accumulation of furniture superfluous. The Gothic style never took firm hold in Italy, though occasionally Gothic tracery is found in the furniture of Venice and Tuscany.

RENAISSANCE

The Renaissance, which originated in Italy in the early years of the 15th century, gradually brought about a complete change in the domestic furniture of that country and of Europe. The classical tradition had never been entirely lost in Italy. Traces of Roman greatness were to be seen in many places, though excavation was only undertaken with the aim of obtaining building materials from the ancient ruins. When a deliberate return to old models was made, furniture gained an importance that it had not

known hitherto. Columns, capitals, entablatures, pediments and other architectural features provided the skeleton of the structure, and the purpose of the cabinet or table, or whatever it might be, was subordinated to its form. The joiner borrowed from the architect. The furniture of the early Italian renaissance is often very restrained and beautiful. For the more elaborate kind of work, sculpture in low relief and stucco modelled in intricate patterns were much used. The stucco was usually gilt all over and picked out in colours. Such pieces became elaborate and costly works of art, though it must be admitted that they were a by-product of the furniture-maker's craft. Carpaccio's painting of St. Ursula's dream, in the Academy at Venice, gives a most attractive idea, though in some measure fanciful and exaggerated, of an Italian interior in the last of the 15th century (Pl. II., fig. 1). The bed is of a form allied to the great panelled bed of northern Europe, but the heavy curtains are not required in a room flooded by the light and warmth of the early morning sun. There is a bench along one wall, an arm-chair, a stool and a low table. A cupboard is let into the wall, and a smaller cupboard holds books and other articles. The ceiling is panelled and the windows are shuttered, with leaded glass lunettes above.

There was no class of furniture on which the wood-carver's and stucco-modeller's skill was more exercised than on the cassone or marriage-coffer, provided and filled for the bride. In addition to the elaborate relief-work and gilding, these coffers were often painted on the front and sides, and occasionally inside the lid as well, with appropriate scenes executed by some of the chief artists of the day. The cassone of the 16th century illustrated (Pl. III., fig. 1) is carved walnut. At times these chests imitate the forms of the ancient Roman stone sarcophagi. Walnut, a common wood in Italy, was an admirable material for delicate carving. The panelling of rooms was sometimes finely carved and inlaid. The Hall of Exchange at Perugia (Pl. II., fig. 3) shows the panelling, with pilasters and cornice, and a fixed bench along the wall. A large writing desk is built out into the hall. Italy did not need the heavy draperies of colder regions, and the dry climate rendered fresco-painting durable on the walls. The fixed writing desk here seen is the forerunner of the writing bureau, which became an indispensable article of furniture as the practice of writing became general. A type of chair much favoured in Italy, and often richly carved and gilded, was evolved out of a simple joiner's contrivance of mediaeval times. The seat was a small wooden slab, generally octagonal. It was supported at front and back by two solid boards cut into an ornamental shape. Another piece of wood, in the shape of a half-opened fan, formed the back. The tables were generally oblong, supported by columns, consoles or terminal figures, with a long stretcher running from end to end.

In Italy the domestic arts were not relegated to a place inferior to those which it has been customary, since the 18th century, to designate as the "fine arts." The amazing versatility of the great artists of Italy is largely accounted for by this circumstance. The influence of the Italian furniture of the renaissance soon spread into neighbouring countries, revolutionizing the furniture-making of Europe.

Austria and Germany.—Italian models were followed in the Austrian provinces to the north. The cabinet makers of Augsburg and south Germany evolved an elaborate type of work based on the example of Italy. Cabinets had doors in front, which revealed an arrangement of drawers and compartments inside. They were covered with veneering and inlay of tinted woods, and details were delicately carved. Rooms were panelled in harmony with the furniture. The inlaid writing desk of Christoff Müller, of Augsburg, made in 1555, now in the Berlin museum, is shaped at the end like the façade of a mansion of the Renaissance. The cabinet shown (Pl. III., fig. 3) is of oak, with veneering of Hungarian oak and other woods, and mounts of tinned iron. An oak coffer, with inlay of sycamore and oak, is a representative example of north German furniture in the earlier part of the 17th century. It bears the arms of the city of Lübeck.

France.—The French monarchs of the 16th century invited Italian artists to the court. They were employed in extensive undertakings, and the forms they introduced were generally fol-

lowed. Italian models in furniture were closely imitated. The carved walnut furniture of France in the 16th century is remarkable for gracefulness and delicacy. Sometimes it is relieved with inlay of small plaques of figured marbles and semi-precious stones. Elaborately-carved oblong tables were supported by consoles or fluted columns, connected by a stretcher surmounted by an arched colonnade. Cabinets and chairs followed Italian shapes. As in other countries where a tradition has been imported from outside, the influence was largely restricted to the capital and to districts under the influence of the court. Older local traditions lingered in the remoter regions. In France, for example, the distinctive furniture of Brittany and Normandy has retained its local characteristics down to the present day.

Spain.—In Spain the alien influence came at an earlier time and from remoter parts. With the invasion and occupation of the south by Arabs and North Africans, in the 8th century, the greater part of the peninsula became virtually an oriental country, and so it remained for seven centuries. After the expulsion of the last Arab ruler, at the end of the 15th century, many "Moriscos" still remained in the country, and the intelligent and industrious craftsmen among them still worked for the Christian rulers of the land in their own traditional styles. The vaulted, coffered ceiling in pine wood, elaborately carved and painted, reproduced in fig. 14 comes from the palace at Torrijos, near Toledo. It was built at the end of the 15th century for Gutierrez de Cardenas and his wife. Several types of these oriental panelled or coffered wood ceilings are found in Spain. The fine pair of carved and gilt wood doors reproduced (Plate III., fig. 6) recalls the Saracenic work of Egypt, but, nevertheless, it is typical of southern Spain in the 14th century. The Latin inscription in Gothic lettering will be noticed. A type of cabinet known as the *vargueño* is typically a Spanish production—a medley of European and oriental elements. The upper part is a chest, generally elaborately mounted in wrought iron, with a massive iron lock to the drop-front. When the front is lowered, an elaborate arrangement of drawers and recesses is revealed, often with ivory inlay, gilding and brilliant colouring. Sometimes the base is another chest with cupboards. Later examples have supports with baluster legs and arcading elaborated from French or Italian models. The chest itself is sometimes decorated under the same influence. Mediaeval Spanish furniture has various foreign elements. The buffet already referred to recalls French work. The iron-mounted coffer, originally painted all over, and bearing shields of arms is a Spanish adaptation of the Italian cassone. Folding chairs of X-shape, with mosaic inlay of ivory and coloured woods, were much in use in the 16th century. There is a tendency for Italian models to be followed in the furniture of the 16th and 17th centuries. In a country so renowned for its iron-workers, it is not surprising to see that bracing-irons of fanciful workmanship are often attached for strength to tables and benches. A Catalan bedstead of the 18th century with painted back is reproduced.

Low Countries.—Perhaps the Italian renaissance found its most characteristic expression outside Italy in the Low Countries. The Gothic furniture of earlier times was solid and strong, with linen-fold pattern and intricate tracery. Its use is exemplified in the work of the contemporary oil painters, whose work gives so convincing a picture of the prosperous and comfortable domestic life of those industrious provinces in the middle ages. Rooms were lofty and spacious. The walls were wainscoted in oak or covered with embossed and painted leather. Windows were partly enclosed by glass panes, often embellished with heraldic and figure ornament, and partly by inside shutters of oak, studded with nails. When the shutters were thrown back, light and air were provided at the same time, for numerous Dutch pictures show that in many cases there was no glass behind them. Chimney pieces, with overmantels carried up to the ceiling, were embellished with marble columns and elaborate carving, and similar architectural ornament flanked the doorways. Heavy oak tables (sometimes "draw tables," which could be extended to twice the length) had massive bulbous legs and solid stretchers. The beds in the corners of the living rooms were heavily draped. Folding wooden chairs and low stools with more or less elaborate turnery, were still used,

besides a new type with baluster formed or twisted legs, arms, and straight backs heightening as the 17th century went forward. The leather upholstery of seat and back were replaced by caning in the latter half of the century, when the high back had a narrow panel flanked by balusters or columns resembling the legs. Low chairs with back, arms and ears in one solid piece, were stuffed and padded, and upholstered with tapestry, embroidery, velvet or other material, showing that the limit of domestic comfort had by that time been reached. Large folding screens with leather panels, or others of lacquer-work imported from the East, kept out the draught. Lacquered furniture was also imported from China and Japan, and travellers learned the secret of this specifically oriental craft, so that imitations were made in Holland, as well as in France, north Italy and elsewhere. The great tapestries for which the Netherlands had long been famous afforded additional protection from the cold air, and oriental pile carpets were used as table-cloths, for it was not yet customary to spread them on the floor, where they would have accorded ill with the habits of domestic life.

Scandinavia.—In Scandinavian countries much domestic architecture continued to be of wood, and the furniture remained simple and primitive. Relief was afforded by painted linen hangings, sometimes representing biblical scenes, with the figures in contemporary peasant costume, and by brightly-coloured cushions in embroidery or tapestry. Houses of the well-to-do contained furniture from north Germany or the Low Countries, providing models which the local carpenters might copy.

The Baroque.—During the 17th century the baroque (*see* BAROQUE ART), had a drastic effect upon furniture design. Large wardrobes and cupboards had twisted columns, broken pediments and heavy mouldings. The Venetian chair of the later years of the 17th century, reproduced (Pl. IV., fig. 1), is an admirable illustration of the tendencies of the time. It is of carved walnut, upholstered in red velvet.

The baroque style owed much to the oriental influence which swept over Europe in the 17th century, when several of the European maritime countries established regular trading relations by sea with India and the Far East. Besides the furniture and domestic goods imported from the East, the oriental craftsmen worked, for export, in a pseudo-European style, from designs supplied by the traders. Heavy tropical woods were also brought to Europe, and from these furniture was made which borrowed much from the prevailing taste for oriental elaboration. Ebony cabinets with waved mouldings, intricate carvings in low relief, and profuse inlay in tinted ivory and coloured woods, were made in Italy, Germany and the Low Countries. The *ébéniste* then acquired his name. A Dutch cabinet of the 17th century, in carved ebony, inlaid in ivory and coloured woods, is illustrated (Pl. IV., fig. 2).

Later French.—In France, the Italian influence of the 16th century was gradually assimilated, and a national style of furnishing was evolved which soon spread its influence into neighbouring countries. The "styles" of Louis XIV., the Regency, Louis XV., Louis XVI., the Empire and so forth, have passed into the phraseology of Europe generally, and their influence has operated wherever the terms have been used.

The reign of Louis XIII., covering most of the first half of the 17th century, was a time of transition. The fame of his son and successor, Louis XIV., the great monarch, might suggest that the outlook of a great nation was then modified and enlarged by the force of a single personality, but it was the national spirit which created Louis XIV., and his times. Expansion in Asia and America, and the growth in the national wealth, were the causes which led to the building of Versailles and the *Galerie d'Apollon* of the Louvre. The great "Salon" now came into being, and the number of separate apartments was multiplied. A suite would comprise a vestibule, ante-chamber, dining-room, salon, state bedroom, study and gallery. Stately and spacious staircases were provided. The interior economy of the modern house dates back to this time.

The Gobelins factory, which still remains a national establishment, was founded under Louis XIV. for the production of *men-*

bles de luxe and furnishings for the royal palaces and the national buildings. Charles Le Brun was appointed the first director of the Gobelins. Furniture was veneered with tortoiseshell or foreign woods, inlaid with brass and ivory, or heavily gilt all over. At times it was even completely overlaid with silver. The name of André Charles Boulle (*q.v.*) is particularly associated with this tendency. His cabinets and tables were completely covered by sheets of tortoiseshell and brass cut into intricate patterns so as to fit into one another, the tortoiseshell alternately forming the pattern and the ground. (*See INLAYING.*) The light fanciful "grotesques" of Bérain were much used for this work. Heavy gilt bronze mounts protected the corners and other parts from friction and rough handling. An example of this work, of a later period, in the Wallace collection, London, is shown in Plate IV., fig. 3. In ancient times, folding chairs might be of iron or bronze, and iron hinges and mountings have, of course, been used at all times where strength was required. The massiveness and elaboration of the furniture under Louis XIV. was followed by the rococo style of the regency in the first half of the 18th century. This style owes more to the influence of Chinese art than any other. The famous writing-table of Louis XV. (Pl. IV., fig. 4), exhibited in the Louvre, was the work of the celebrated furniture makers, Riesener and Oeben. It is said to have taken nine years to make. Furniture under Louis XVI. showed some return to classical models. Curved surfaces were replaced by severer design, and straight, tapering legs succeeded the cabriole. A limit of elegance unknown before was reached. Plaques of the delicate porcelain of Sèvres, with ornament painted in brilliant colours on a dazzling white ground, were freely employed upon tables and cabinets (*see* Pl. IV., fig. 5). The graceful tapestries of the Gobelins and Beauvais replaced the heavy velvets of the 17th and early 18th centuries for upholstering chairs and settees and for window hangings. The bedstead shown (Pl. IV., fig. 6) is of carved and gilt wood, with coverings and canopy of pale blue silk. The French furniture of the 18th century set the standard of elegance and refinement for the whole of Europe.

Rooms were rebuilt or remodelled in accordance with the taste of the day. Elaborate parquet flooring was introduced before the close of the 17th century. Walls were enriched with relief work and gilding. Tall glass mirrors, reaching from floor to cornice, were set between the windows and protected by console tables. Ceilings were painted by some of the chief masters of the time. Later, when more restrained types of furniture were made, walls were painted white, with mouldings picked out in gold. The plain whitewashed ceiling did not come into favour before the 18th century was well advanced.

Two French domestic interiors here reproduced are separated by a century of time, but the contrast is greater than that involved in this circumstance. The earlier is provincial work, and it differs materially from the work then being done for the court of Louis XIV. The other is from Paris, showing in a marked degree the refinement and delicate workmanship of the period of Louis XVI. The panelled room from the Château de la Tournerie, near Alençon (Pl. IV., fig. 7), is of oak, painted and gilt, and embellished with embossed leather panels enriched with painting and gilding. The château dates mainly from the 16th century, but the panelling was erected between the years 1682 and 1694 by Alexandre Sévin. It bears his crest and initials with those of his wife. The boudoir (Pl. IV., fig. 9) is from a house in the rue Vieille du Temple, in Paris. The room is said to have been erected under the personal supervision of Queen Marie Antoinette and Madame de Sévilly, her friend and lady of honour.

Later Styles.—Towards the end of the 18th century the influence of the discoveries that had been going on at Pompeii penetrated into Germany and Austria, and interiors were decorated in the light and fanciful style exemplified in the wall-frescoes of the Pompeian houses. About this time a vogue arose for draping interiors into the resemblance of a tent. The draperies completely covering the walls were sometimes pleated, and if the ceiling was high enough it would be concealed by a kind of sloping velarium. A bed would be enclosed by festoons of drapery.

The influence of the well known cabinet-makers of England in

the second half of the 18th century, was reflected in the work of the furniture-makers of north Germany and Denmark.

The Napoleonic régime hastened the changes then in progress in European furniture-making. The example of Roman majesty was continually in the emperor's mind, and the "Empire" style aped the uninspired decorative formalities of Roman imperial times. Furniture with outcurving legs was copied from representations in Roman reliefs. Griffins and sphinxes were freely used as decorative motives or supports. Beds with rolled ends and stuffed backs, sometimes with drapery above like a gable roof, were the forerunners of the sofa of the later years of the century. The rest of Europe adopted the "Empire" style, of which the chief merit was a return to more sober models after the exaggerated fancifulness of previous styles.

Towards 1825 the reaction came. Earlier fashions were again reverted to, for a time, in a half-hearted manner. The new wealth of industrial and trading communities gave rise to new ideas of material well-being. The comfortable "Biedermeier" style arose in Germany. Furniture was luxuriously cushioned and padded. Thick curtains, festooned draperies, table-covers, antimacassars, tassels and fringes were seen everywhere. The time when these began to be curtailed or to fall into disuse is within the memory of the older generation to-day.

The subsequent tendency to revert to imitations of the furniture of the 17th and 18th centuries is not altogether praiseworthy. It is easier to stifle originality than to revive it when the inevitable need arises. Moreover, there were contributory causes for most of the changes which have been here briefly reviewed, and to copy a type of chair or table when the circumstances which originally gave rise to it are no longer operative is not in harmony with the soundest principles. (*See also the various short articles on pieces of furniture, such as BED, CHAIR, CHEST, TABLE, etc.; also the different styles and periods, such as ROCOCO, BAROQUE, GEORGIAN, etc.*

ENGLISH

Henry III.—A notable early specialist in house decoration in England was Henry III., who gave us Westminster Abbey. The Liberated Rolls of his reign preserve for us all the orders he gave for the adornment of his various castles and manor houses. Larger windows, and, especially, rose windows were built in halls, their painted glass adding to the rich colour decoration that the king loved and obtained at other times by painting "histories" on his walls, as in his Great Chamber at Westminster. His queen had a figure of winter painted over her fire-place there, and spring-like flowers painted on the white-wash of her room at the Tower. Walls were frescoed with histories, including scenes both biblical and classic, and below them often was wainscoting with painted and decorated boarding. Wrought roofs or painted ceilings completed a rich domestic treatment, which was very rare in 13th century England, when walls were bare and hangings were the usual means of decoration resorted to by nobles or rich burghers.

Flanders tapestries, known by the generic name of "arras," were the most favoured material. Solidly woven, they resisted the wear and tear of the movings of great men who had various estates but little gear. Tapestries were hung curtain-wise from wood-quartering set with tenterhooks, and such have recently been renovated at Tattershall castle, where, except for such hangings, the brick structure of the walls was visible, as is seen also

ELIZABETHAN AND JACOBAN INTERIORS

1. The hall at Plas Mawr, Conway, Carnarvonshire, an admirable example of an Elizabethan interior. The patterned ceiling is a product of the school of plasterwork that flourished during the last quarter of the 16th century; the upper part of the chimney piece is also plaster
2. Ceiling in the great chamber at Herrington, Dorchester, dating from about 1615. It is barrel-shaped and worked with an elaborate pattern of floral scrolls, heraldry, beasts and birds. The pendants are a feature of the period
3. Stone hall screen at Wollaton Hall, Nottinghamshire, a residence erected in 1580 by Sir Francis Willoughby. Elizabethan
4. The large or north drawing room at Levens Hall, Westmorland, showing 3 decker chimney piece, plaster work ceiling, and north window with roundels of painted glass. The family heraldry is carved in the compartment above the fire arch; Queen Elizabeth's arms in the centre panel of the top compartment, and the date 1595 in that to the right. The family heraldry also provides the motifs of the six painted window ovals

ENGLISH INTERIORS—SYON HOUSE AND CHATSWORTH

1. View of the great dining room at Syon House, Middlesex, looking east, showing the noble system (introduced to add to the sense of width), the columned apse and the enriched ceiling. The chimney piece is of white marble, and the room is painted yellow with gilded enrichments. Designed about 1762 by Robert Adam

2. The great chamber at Chatsworth, Derbyshire. Late Stuart style. It is wainscoted from floor to ceiling, and the more important panels decorated with carvings in Grinling Gibbon's manner by Lobb, Davis and Watson in 1692-3. The ceiling was painted by Verrio, the famous contemporary Italian artist

INTERIOR DECORATION

PLATE VII

in a picture from an illuminated manuscript produced in Flanders for Edward IV. (c. 1475) of Richard II. feasting (Pl. V., fig. 1). There is no arras, but the king sits under a rich textile canopy, similar material also hanging in front of the musicians' stand. It was not as yet customary to have walls lined with oak, but it was used, and used richly, by the highly expert carpenters of the day for such structural purposes as hall screens and room partitions. They had not, however, taken in hand the chimney-piece, which remained in the domain of the mason who in the 15th century bestowed pains upon its adornment, as we see in the great heraldically carved chimney-pieces at Tattershall, dating from about 1438.

The Development of Panels.—It was not, however, until the days of Elizabeth that this feature became monumental, often reaching from floor to ceiling by the use of superposed classic columns. By that time framed wood linings had become usual, and to them gradually became applied the word "wainscote," which had originally merely meant foreign oak. Such panelling, although only common under Elizabeth, occurred under Henry VIII., the finest and amplest surviving example being probably that in the Gallery of the Wyne, in Hampshire, where the linen-fold carving is enriched by various heraldic badges that enable us to date it from between 1515, when Wolsey was made a cardinal, and 1530, when Catherine of Aragon fell into disfavour (Pl. V., fig. 4).

The same treatment, extending also to ceiling beams and panels, we may still see in such Essex houses as Paycocke's, in Coggeshall, the Granby inn at Colchester or the manor house at Tolleshunt Darcy.

Frescoing walls still continued, but most of it has perished. Some late 15th century representations of Bible scenes have recently been found under whitewash at Cothay, in Somerset, while of Elizabeth's reign a very good example has come to light at the White Swan inn at Stratford-on-Avon, depicting scenes from the story of Tobit.

Hangings, however, still held the premier place as wall coverings. In the early part of the 16th century, the number of sets belonging to kings and great men was almost countless, and a Wyne inventory of 1541 gives sets in almost every room of the house, including the chambers of dependents. A somewhat similar effect was reached by cheaper means, and there was a great output of *tempera*—painted or "stained" cloths, using the same subjects as tapestry—histories from biblical or classic sources, verdure of woods and fields with beasts and birds and decorative subjects passing from Gothic to Renaissance *motifs*. Nearly all this "counterfeit arras" has perished, but a set displaying the Acts of the Apostles survives at Hardwick hall in Derbyshire.

Leather, embossed, painted and gilt, was less used in England than on the Continent, but such woven fabrics as velvets and damasks for the wealthy, and "sayes and bayes" for modest folk, found a place on the walls as well as for bed and window hangings.

The Elizabethan joiner, when his employer's purse permitted, enriched his wainscotings with carvings and inlay and completed the circuit of the room with elaborate oak door-cases and chimney-pieces, using for them classic orders and Renaissance *motifs*. For the most part their work shows an uncultured vivacity rather than a trained head and hand, a knowledge of the anatomy of the human form being very rarely displayed. Typical of the English craftsmen of the day is the great drawing-room at Levens in Westmorland. The chimney-piece, dated 1595 (Pl. VI., fig. 4), is of three-storeys, Doric, Ionic and Corinthian orders being piled one upon the other. Elaborately framed wainscotings, enriched door-cases, plaster-work ceiling and roundels of painted glass in the windows complete the picture.

Screens continued to be used in halls even when they were of single-storey height, as at Cuckfield in Sussex, dated 1581 (fig. 5). The vast majority were of oak, but in important houses, stone was sometimes used, as at Wollaston (Pl. VI., fig. 3) and Montacute. Stone and even marble were used for chimney-pieces, especially in James I.'s reign when Max. Colt, "carver in wood and stone of all his majesty's works," provided three marble chimney-pieces for Hatfield; and we find similar ones at Knole and Bram-

hill. One example, however, there is of the previous reign; a noble chimney-piece in the Gallery at Cobham, wrought in 1599 by Giles de Whitt (Pl. V., fig. 2).

Plaster Ceilings.—Although wainscotings became the normal wall treatment under Elizabeth and her immediate successors, yet there was still scope for tapestry, and also for enriched plaster ceilings consisting of narrow interlaced ribs forming geometrical patterns. There are interesting examples at Plas Mawr in Conway, where the same material forms the upper part of chimney-pieces, the royal arms indicating a date in Elizabeth's reign (Pl. VI., fig. 1). Such treatment of ceilings was often very elaborate in those distinctive Elizabethan rooms, the long gallery and the great chamber, which were often upstairs; and greater height was obtained by using the roof space and forming a barrel-shaped ceiling. They exhibited not only the narrow ribbing of Elizabeth's time, but also the broad bands with enriched soffits that came in under James I., one of the finest examples of which is at Herlington, near Dorchester, dating from about 1615 (Pl. VI., fig. 2).

The Staircase also reached its final development in this reign. In mediaeval times, the winding newel form, sometimes of wood but more often of stone and never very wide or easy in gradient, had prevailed. But under Elizabeth it had begun to be placed round an ampler open space, and its decorative possibilities being recognized, enriched newel posts, balusters and strings were given to it. The idea was developed under her successor, and one of the finest, both in planning and execution, is the great stair at Hatfield, dating from 1610. The newel posts are richly carved and surmounted with figures so skilfully sculptured in wood that they may well be the work of Colt himself. Here, and at Audley End, the halls, which still rise to the roof, are fitted with great screens embodying all that is best and finest of the native design and workmanship of the time.

Jones and Webb.—A feeling for classic reserve was now spreading and the Late Renaissance period might well have begun under Charles I. but for the political difficulties that checked the zest for fine building. Returning from Italy in 1615, Inigo Jones introduced the new style in the Whitehall banqueting house and the Queen's house at Greenwich, and, despite English conservatism at first and the Civil War and the Commonwealth afterwards, we find his hand and that of his kinsman and associate, John Webb, at Wilton, Forde abbey and Thorpe, all houses altered or built by men on the winning, or Parliamentary, side. Also built under the Commonwealth is Coleshill, the earliest and one of the best of English country seats where classic form and Italian tendencies prevail.

Wood was less used than stone and stucco by the Italians for wall linings, and Inigo Jones favoured their materials as well as their manner. Webb, however, and other Englishmen were more northern in taste and native in training, so that wood held its own in England till the end of the century. But it had to conform to the new taste. Wainscotings must no longer be framed sheets of small panels in the nature of movable linings, but must simulate wall structure. They become architecture, not furniture. Vast panels thrust forward from their stiles by bolelection mouldings are made up of two or more boards skilfully chosen and worked to hide the joint, even where they are left unpainted, as by Grinling Gibbons, the amazing delicacy of whose carving in lime is obscured by paint but stands out excellently against an oak background.

The Age of Wren is characterized by an architectural treatment as of stone but with the natural surface showing, as exemplified by the admirably designed and executed joinery not only in churches and public buildings, but in houses, such as Belton and Chatsworth (Pl. VII., fig. 2). The passage from the early to the late Renaissance period is a change not only of style but of spirit. During the former, the craftsmen retained much of the independence of action of mediaeval times, and the work was free and forceful but not fine. But perfection, reached through discipline, is the essence of the classic spirit. The design becomes more learned and includes detail which it was the business of the executant to follow obediently but skilfully. The field of individuality was closing for the craftsman, but that of dex-

terity was opening wide. Thus mastery of technique is a distinguishing feature of men like Gibbons and Hopson, Strong and Tijou,—natives and foreigners who combined to give finish to the decorative output of the later Stuarts.

The Georges.—Even during the last years of that dynasty, and still more under the Georges, the wood-workers found their domain contracting. Italy exerted more and more influence, stone and stucco became more used. Vanbrugh began and the Burlingtonian school continued the stucco, stone or marble halls of the new Whig palaces, such as Castle Howard and Blenheim under Anne, Houghton and Holkham under George II., Syon and Heveningham under George III. Stone treads and iron balustrading, moreover, were introduced for staircases, although in this feature the joiner long retained the lead. Under Charles II. the work is solid with massive balusters or open panels elaborately carved under a broad hand-rail, as at Wolseley or Sudbury. But with the 18th century it becomes lighter and more delicate, although equally finished and rich, as at Beningbrough in Yorkshire where, in 1716, we find the joiner still supreme, and are enchanted with the quality and quantity of the wood-work as it appears there and in so many doorways and chimney-pieces, shutterings and framings in George II. houses, like Godmersham in Kent (Pl. VIII., fig. 2).

Elsewhere, however, it is the Italian stuccoist who holds sway and riots in the exuberant ornament that was so wonderfully reached by experts in *il stuc*, and of which we find outstanding examples at Mereworth and Houghton (Pl. VIII., fig. 1), Moor Park and Clandon.

Textiles.—But it was not only stone and plaster that was driving the joiner from walls of rooms. Textiles became increasingly popular. For them as for wood the late Renaissance demanded a more architectural handling and they were no longer hung but stretched on frames fixed above a dado. Not only tapestry but cut velvets and damasks were favoured, and a single order for these given by the duchess of Marlborough in 1707 was for over 3,000 yards. Indian calicos and other lighter and less expensive textiles were also fashionable, but the most serious, because still cheaper, competitor to wainscoting was paper, which, from being a 17th century rarity became a prevalent feature as the 18th century progressed. During George III.'s reign we notice an increasing lapse from classic restraint and Palladian purity. French rococo joined Italian baroque and was sprinkled with vagaries that passed for Chinese and Gothic. Ceilings, chimney-pieces, door-cases were apt to be so treated, the most astonishing being perhaps those at Clayden in Buckinghamshire.

Adam.—Reserve rather than excess, however, was the English characteristic, so that baroque and rococo gave way to the choice delicacy and clean lines that were the basis of the style of Robert Adam, who commenced his London practice in 1759. With him the despotism of the architect over the craftsman was complete. No detail of decoration or furnishing escaped him: his rapid and precise draughtsmanship covered the whole ground. The executant must not depart one hairbreadth from the drawing supplied, but he must have reached exquisiteness of technique. This spirit, joined to that of severity and restraint in design, makes the perfection reached during the last decade of the 18th century a little chilling and inanimate, implying a ceremonious rather than a domestic life.

Adam's clients, however, were for the most part the Italy-loving leaders of an aristocratic and artificial age, who affected a palatial and ultra-architectural treatment of interiors, as shown by the painted wall surfaces broken by pedimented door-cases, the columned apses and the scooped-out niches that we find in the hall at Kedleston, the dining-room at Syon (Pl. VII., fig. 1) and the saloon at Heveningham. In smaller and more domestic rooms, if the materials differed, the same practice obtained. Even carpets were made to reflect the ceiling design. Wood was never left unpainted, and although the joinery is still admirable, the enrichment is often in composition or in pewter. We find specially designed temple-fronted book-cases, and specially painted pictures set in specially designed frames fixed and painted to form an

integral part of the wall structure.

"Gothic."—So much logical completeness, such wholly unemotional perfection, was bound to stir up opposition, especially at a time when a new romantic school was forming and the cult of the picturesque was gathering strength. Although architecture and decoration—indeed, life itself—were treated much as playthings by Horace Walpole, and Strawberry Hill was a mere confectioner's romance, yet his influence was large and helped to turn James Wyatt from the classic manner, which he had practised as successfully as Adam, to pseudo-Gothic. For decoration it was a singularly unfortunate introduction. What in the mediaeval interior was not movable was truly structural, and not imitative of it; so that not only did flimsy wood, plaster and paper decorations entirely miss the Gothic spirit, but they were introduced as the trappings of houses designed to meet entirely different habits of life. Thus, when the 19th century was reached, a plan that, in the disposition of parts, the shape of rooms, the height of ceilings, suited the habits and views of the day, might be decked out by the architect in what he was pleased to think was Gothic or Tudor, Roman or Greek, French or Italian, Egyptian or Indian.

The last half-century has been largely a struggle to get free from this welter of confused aims and misunderstood styles, but with all this there is too great a reliance on the past, on the halcyon days of the Renaissance styles, early and late. The best craftsmen are employed on mere copying, on the production of "Period rooms," so that among decorative styles we cannot include one of to-day.

ENGLISH FURNITURE

English furniture has developed in the course of many years from a few primitive types to highly specialized varieties; it has evolved gradually with the progress of civilization. So little survives from mediaeval times that information must be sought in contemporary references, supplemented by representations in illuminated manuscripts. Most of these miniatures are of foreign origin; but they are reliable evidence, for the governing classes were Continental in their habits and the equipment of their homes. The furniture made for them was strongly influenced in form and detail by Gothic architecture, and was freely embellished with colour and gilding. English oak was the chief material, but softer woods were also used.

The furniture usually found in important houses consisted of beds, chests, cupboards, tables and stools. These objects are the basic types from which the whole evolution can be traced. Wills and inventories prove that draped bedsteads were treasured possessions of mediaeval householders, prized not for the rough framework but for their magnificent woven and embroidered hangings. These draperies consisted of a celure (back), tester (canopy), curtains and valances, and on them were worked scenes from the chase and many fanciful devices. Such beds were placed in the principal living rooms, and served as couches in the daytime. Chests were almost the only receptacles for valuables. They survive in large numbers, many 13th century examples being preserved in churches. The fronts, formed of stout planks, are pegged into wide uprights, plain, or carved with grotesque monsters. Later specimens are sometimes carved with arcades of Gothic tracery, scriptural incidents or mythological subjects. Large travelling chests, called "standards," were bound with iron and covered with leather. At the ends were iron handles through which ropes could be passed to facilitate transport. The guild of cofferers already existed in Edward III.'s reign, but could not prevent the

ENGLISH FURNITURE OF THE 18TH CENTURY

1. Commode veneered with satin wood and decorated with marquetry. About 1770
2. Bookcase of carved mahogany. About 1745. From Mr. J. Thursby Pelham
3. Commode chest of drawers. Carved mahogany. About 1760
4. Bureau bookcase veneered with burr walnut, gilt carved. About 1730
5. Mirror in frame of wood, carved and gilt in the rococo style. Probably by Chippendale. About 1755
6. Cabinet on stand; walnut decorated with floral marquetry. About 1685
7. Side table with marble top, carved and gilt. In centre is figure of a child seated on a shell. Designed by William Kent. About 1730. Houghton Hall
8. Armchair of carved walnut, upholstered in red velvet. About 1720
9. Side table with classic decoration; carved and gilt. Designed by Robert Adam about 1770. From 20, St. James's Square, London

importation of Danzig chests and others of overseas work. On a dresser in the hall flagons and cups were displayed. It was an open framework of shelves with a projecting lower portion, sometimes enclosed by doors. Side-tables, used for serving meals, were in the form of a chest mounted on legs, the panels pierced with Gothic tracery. What are now termed cupboards were known as ambries. Existing specimens are of massive construction with cross divisions and foliated iron hinges. Until the close of the middle ages chairs were lofty, throne-like structures, few in number and regarded as symbols of authority. The ordinary seats were chests and stools with benches sometimes fixed to the walls. Mediaeval dining tables were of trestle construction, boards of oak or elm resting on a series of central supports. They had removable tops and could be stored away after meals. Two examples still remain at Penshurst Place, the tops, nearly 30ft. long, being supported on carved trestles with cruciform feet. Towards the end of the 15th century panelled framing, or joinery with mortice and tenon, replaced the primitive method of construction in which planks split or sawn from the log were roughly put together with pegs. At this period panels were often carved with the linen-fold pattern, so called from its resemblance to linen arranged in upright folds.

Tudor.—In the Tudor period the character of domestic furniture was gradually transformed by Renaissance influence, carved profile heads, dolphins and foliated scrolls appearing on structures which at first remained Gothic in design. Henry VIII. employed Italian craftsmen for the equipment of his new palaces, and their works were imitated by native craftsmen with less delicacy and finish. Walnut, more readily carved than oak, was extensively used, and, though much of this furniture was imported, there are undoubted English examples. Under Elizabeth inlay consisting of arabesque or chequer patterns in coloured woods came into vogue as decoration. There was a notable increase in domestic comfort. Harrison about 1587 reported that costly furniture had descended "even unto the inferior artificers and manie farmers." By this time the style had emerged from foreign tutelage and assumed a character distinctively English. It is coarse and vigorous, prodigal of material and floridly enriched. The round arch figures prominently with corbels and grotesque terminals; foliated strap-work fills the decorative areas, while nothing is more characteristic of Elizabethan furniture than vase and melon-shaped supports of prodigious girth profusely carved. In the matter of new types there was little innovation, but capacious presses were provided for clothes and mirrors of glass in highly decorated frames were becoming known at court. Chairs were more abundant. They had panelled backs and joined frames and could be readily moved; in some the woodwork was hidden by rich fabrics. Beds were now constructed of wood throughout, a panelled back and posts supporting a ponderous tester. Joined tables with "draw," or extending, tops ousted the trestle variety; while court cupboards and buffets laden with plate adorned every well-appointed hall.

The Stuart Period.—This increase in domestic comfort continued until the outbreak of the Civil War. From James I.'s reign padded and upholstered seats survive, and at Knole may be seen chairs of X pattern covered with silks and embroidered velvets. A very remarkable specimen, in which Charles I. is said to have sat during his trial, has lately been acquired by the Victoria and Albert museum. Such chairs show Continental influence, but the main output was insular and traditional. The style gradually lost its rude vigour. Structural members dwindle in scale, and fanciful carving degenerates into stock patterns, eked out with applied bosses and spindles. The furniture of the Protectorate is, for the most part, severe and angular.

After the Restoration there was a striking change. The exiled court on its return introduced French fashions, and austerity gave place to lavish display. Furniture became lighter, more highly finished, and better adapted to varying needs. Walnut was the favourite material. Joinery developed into accomplished craftsmanship and new processes appeared, notably veneering wide surfaces with thin sheets of wood into which floral patterns in marquetry could be inserted. The passion for colour found an even better outlet in lacquer decoration. The importation of

works of art from the East had begun in Tudor times, but was of small account until after the Restoration. Then the taste became widespread. Evelyn and other observers reporting their friends' houses to be furnished with Indian screens or panelled in the finest Japan—descriptions implying oriental lacquer. Such things came from China and were soon imitated in England, the art of covering furniture with successive coats of coloured varnish being known as "Japanning." New forms of decoration coincided with a multiplication of types. Day-beds, a form of couch with an adjustable end, and winged arm-chairs served for repose. A little later, sofas with back and arms carried comfort a stage further, patterned velvets mainly of Venetian origin and damasks woven at Spitalfields being the usual coverings. Bureaux with an enclosed desk were produced towards the end of the century, and chests of drawers came into general use. Mirrors were no longer rarities after the duke of Buckingham had established his famous glass-works at Vauxhall, the frames being carved, lacquered or inlaid. Charles, says Evelyn, "brought in a politer way of living which passed to luxury and intolerable expense." An example of this extravagance is afforded by the tables, mirrors and stands covered with embossed silver with which the king's mistresses furnished their apartments. Fashions succeeded each other with great rapidity. Chairs show these changes most clearly, developing in a brief period from mere seats into movable decoration. They had floridly carved crestings and stretchers, while for the structural members many varieties of turning were employed. Scrolled legs were general under Charles II., being succeeded by taper and baluster forms a few years after his death. In beds of this period, the tester, back and posts are covered with material pasted on to the wood and matching the hangings. They were of enormous height with elaborately moulded cornices, and had ostrich plumes or vase-shaped finials at the corners of the tester. The ornate stands and side tables of this age demand special notice, for, profusely carved and often gilt, they are among its most striking productions.

The 18th Century.—At the beginning of the 18th century a new style arose. It was simple and dignified, based upon curved lines and entirely admirable in its insistence upon form. The cabriole-shaped support with claw-and-ball or paw feet was a salient feature, and early in the development stretchers were eliminated. This style depended largely upon finely figured walnut veneers, and made but a sparing use of carved ornament. Chairs changed their character completely. They had hooped uprights and vase or fiddle-shaped splats curved to support the back, beauty and comfort being combined in the design. Tall-boys, or double chests of drawers, cabinets fitted with shelves, and bureaux in two stages met the demand for greater convenience, while the types already known were much improved. About 1720 mahogany began to supersede walnut as the fashionable material, its consumption increasing with the repeal of the heavy import duties. The furniture which had prevailed during Anne's reign no longer satisfied the governing class, whose taste inclined to ostentatious magnificence. They demanded something grandiose and cumbrous, suited to the great Palladian houses for which it was destined. Inspired by the contents of French and Italian palaces, such furniture was largely the production of architects. William Kent, the most celebrated, having travelled in Italy before starting practice. The basis of design was classical, the manner baroque. Columns, architraves and entablatures are prominent with terminal figures and heavy scrolled supports, masks and acanthus scrolls being favourite ornaments. The carving was bold and often masterly, gilding, freely used, enhancing the effect. At Houghton, Holkham, Rousham and elsewhere, Kent's furniture may be seen in its proper environment, gilt mirrors and side tables with sets of chairs and settees covered with patterned velvets recalling the vanished splendours of that opulent age.

About the middle of the century a fresh wave of French fashions produced an Anglicized version of the rococo style. It was romantic in conception, fantastic and capricious in the manner of its working out. It banished the straight line and made asymmetry a cult, while it sought its ornament in conventionalized

renderings of natural forms—shells, foliage and flowers. With it flourished the Gothic and Chinese “tastes,” the one a travesty of a forgotten art, the other an attempt to exploit the furniture of an unknown land. Architects with a hold upon tradition were now challenged by cabinet-makers who produced their own designs. Chippendale, Ince and Mayhew, Johnson, Manwaring and many others published illustrated trade catalogues to advertise their wares. Of these works Thomas Chippendale's *Director* is the most important. It affords an apt summary of contemporary tendencies, and is at once eclectic and original. Chippendale borrowed his rococo from Meisssonier, but depended much on his own fancy for what he deemed Gothic or Chinese. It was an age of specialization, and many varieties of furniture are represented, ranging from extravagant side-tables for saloons to ingeniously contrived little objects for bedrooms. In the explanatory notes mahogany is generally recommended, but many of the designs are to be japanned or finished in burnished gold. The contents of such houses as Nostell and Harewood (where the original bills are preserved) show Chippendale to have been a craftsman of genius; though he had many rivals scarcely less gifted. His name affords a convenient label for furniture of the middle of the 18th century—mostly the work of other hands. The classical reaction, which set in shortly after 1760, swept away tortuous forms and terminated licence in design. Robert Adam, whose name is inseparably associated with this movement, had, like earlier architects, studied in Italy. His fastidious taste rejected the art of the later Renaissance, and sought inspiration in the remains of antiquity. When he was given a free hand, furniture and decoration were included in his architectural schemes. What he could achieve when “the subject was great and the expense unlimited” Syon and Nostell remain to show. They are brilliant essays in the “antique style” with the contents carefully thought out in relation to their surroundings. This furniture makes a learned use of classical ornament, but paterae, husks, rams' heads and urns are less eloquent of the change than the symmetrical structural lines. At this time commodes and other objects intended for display were often of satinwood with marquetry or painted decoration, the latter copied from designs by leading artists. The style as Adam conceived it was too severe and scholarly to be widely appreciated. It was modified by contemporary cabinet-makers, and may be seen translated into popular terms in Hepplewhite's *Guide* (1788). In the process the furniture has lost its ceremonial character, and become simple, homely and graceful. It retains, for the most part, symmetry of form and excellence of proportion. Heart and shield-shaped backs on chairs and settees with tapered and fluted supports are noticeable features, while feathers, wheat ears and shells are prominent in the painted or inlaid decoration. The movement was towards lightness and elegance, and furniture of a distinctly feminine kind is found represented in Sheraton's *Drawing Book* (1791). This period saw the highest technical accomplishments, and a degree of specialization hitherto unapproached. Sheraton's designs for fitted washstands, dressing- and work-tables are triumphs of ingenuity and eminently practical.

At the end of the century a strange archaeological revival, based upon a closer study of Greek, Roman and Egyptian remains produced the Empire style and that modified version of it which became current in England. The chief English exponent was Thomas Hope, an amateur designer with some antiquarian knowledge; but when the fashion was taken up by cabinet-makers the results were often woefully incongruous. They essayed the production of Roman bookcases and sideboards undeterred by the lack of classical precedents, and to what depths of incongruity they descended may be seen in Sheraton's later publications and in George Smith's *Household Furniture*. Rosewood was used with bronzed or gilt ornament and metal inlay, sphinxes and animal terminals being favoured as supports. With the last phase of this style, prolonged into the reign of George IV. and growing ever more grotesque, the making of furniture ceased to be an art. The introduction of machinery ended the craftsman's direct responsibility and robbed him of pride in his work. The old tradition of sound craftsmanship lingered, and may be detected even in the

cumbrous productions of the Victorian age, devoid though they be of any aesthetic interest. It may confidently be said that the domestic arts were never at lower ebb than during this period.

The Pre-Raphaelites and Modern Movements.—Early in the '60s the complacent acceptance of mass embellished with ungainly ornament was challenged by the movement inaugurated by William Morris and a group of pre-Raphaelite artists. They sought to rehabilitate craftsmanship, and with this end in view their sympathies were naturally drawn to the middle ages when craftsmanship was in its prime. Their work is distinguished from the earlier Gothic revival by greater understanding and a regard for modern needs. That it can wholly escape the charge of being “sham mediaeval” cannot be maintained, but it was sincere in intention and provocative of thought. Morris realized part of his ambition, for he trained a company of enthusiastic and highly skilled craftsmen. The propaganda spread in spite of the prevailing Philistinism, and a marked improvement in taste was the result. For an appreciative few Morris furniture continued to be made, and, among the inheritors of his traditions, Ernest Gimson deserves honourable mention. The movement was, however, too typical of a time when the arts had become disastrously divorced from life. It found its chief supporters among a cultured minority with exclusive standards and a somewhat superior attitude; in consequence there was more than a hint of the “precious” and artificial about the furniture made for them. A notable result of pre-Raphaelite activities was to direct attention to the striking merits of furniture which had been banished by the Victorians. It was rescued from obscurity and the collecting habit spread, rapidly producing a huge crop of “fakes” and reproductions. This habit has undoubtedly determined the character of English furniture for nearly 50 years. It has stifled originality and degenerated too often into an unintelligent craze, while it must be held responsible for the cheap and horrible travesties of historic styles, which under the label “period” have done so much to degrade public taste. In the last decade there have been unmistakable signs of a renaissance, and something of the Continental enthusiasm for modern furniture has spread to England. In the productions of this new school fitness for purpose is again considered and great attention is bestowed on the material, many beautiful, exotic woods being used with striking effect. Ornament is unobtrusive (excepting in the more fantastic examples), and even mouldings are kept in subordination. The forms are often eccentric, reflecting the latest aberrations of fashion; attempts to produce jazz or cubist furniture are not unknown. At the present day the opportunities are quite severely limited by the inevitably high cost and also by lack of patronage. The outlook is promising, both on account of the genuine originality sometimes displayed by designers with a firm hold upon tradition, and because fine craftsmanship is again highly prized. The 20th century will possess a distinctive style when a few gifted designers emerge to consolidate the gains already won. (See ENGLISH FURNITURE; LACQUER; TUDOR PERIOD; STUART PERIOD.)

AMERICAN FURNISHINGS EARLY IN THE 19TH CENTURY

1. Mantel from the Gore House, Waltham. About 1799 to 1804
2. Mantel by Robert Wellford, with the Battle of Lake Erie as the decorative motif. Adam style, about 1815
3. Mahogany sofa with lyre ends by Duncan Phyfe. New York, about 1800
4. The oval drawing room at Lemon Hill, Philadelphia, 1798. An interior in the Adam style

INTERIOR DECORATION

Swedish at first on the Hudson and the Delaware and German as well as British in Pennsylvania. Even among the leaders few represented courtly fashion. Hence, the earliest household decoration and furnishing, after the period of primitive makeshifts, reflected rather the character of the common houses of the small towns and rural districts abroad. In these the fundamental element deep into the 17th century, in Germany even into the 18th, was a survival of the art of the middle ages, with its structural emphasis, its simple forms derived from materials, tools and use.

Thus in New England in the 17th century we find the clay-filled walls, the timber houses roughly plastered and whitewashed, or perhaps wainscoted with wide moulded boards, which, standing vertically, served as the partitions. The joists of the ceiling were exposed, supported on heavy moulded summer-beams; the great fireplace was likewise spanned with a huge beam, and was devoid at first of any moulded frame. The effect was one of homely solidity, achieved by the frank revelation and elaboration of every element of the construction.

Into such houses in New England and Virginia went furniture of Jacobean oak, a few pieces doubtless brought over by the leaders, but the vast majority made in America after remembered models, from the abundant supply of native woods, chiefly American oak and pine. They included chests, court and press cupboards, trestled tables and forms and, at first, but a few chairs of the turned or wainscot types. One variety of armchair with turned spindles has acquired in America the name of Carver chair from the familiar example belonging to John Carver, still preserved at Plymouth. Other characteristically American types are two forms of chests found in the Connecticut valley: the "Connecticut chest" of the lower valley, with Jacobean spindles and the panels carved with a tulip decoration; the "Hadley chest" further up the valley, of which the frame likewise has incised carving. In the English colonies the furniture, as well as the woodwork, was generally left without paint or other finish. Inventories of the better 17th-century houses reveal that they contained much in the way of hangings, including tapestries and needlework, as well as treasures of plate made by the American silversmiths of the time, and pewter by local pewterers.

Similar in their generally mediaeval character were the interiors of the Pennsylvania-German houses, where, however, there was a rich colour, in the painted decoration of the chests with motives of birds, tulips and other traditional elements, the illuminated texts, birth and marriage certificates which hung upon the walls. It was the German colonists also who first made any high development of pottery, as in the Pennsylvania slip ware, with similar decorations, and in glass-making, as in the wares of Stiegel and Wistar. The familiar hand-woven coverlets, chiefly of blue and white, were likewise derived from patterns brought in by the German weavers.

Following the evolution of style in England, under the Commonwealth and the Restoration, there appeared in America chairs of the Cromwellian and Carolean types, with spiral turnings and baroque scrolls, with seats and backs upholstered in needlework or with panels of cane. The chest with a drawer or drawers then made its appearance. The founding of Philadelphia by William Penn in 1682 brought to America for the first time the decoration of the period of Wren, which had appeared in London after the great fire and had been developed by Wren and Daniel Marot in the reign of William and Mary. Its influence only became wide in the colonies with the opening of the 18th century. The construction disappeared beneath a formal interior finish. Panelling took the place of sheathing, the fireplace was surrounded by classic mouldings, at first boldly projecting, to produce the chimney-piece. The doors and windows, too, were surrounded by classic frames, and the wall might even be divided, in the finest houses, by pilasters. In the staircase the open string, with carved brackets at the end of the steps, was adopted; the balusters and newels, more slender, were richly turned, often in varied spirals.

Walnut became the favourite wood in furniture, until superseded by mahogany in the middle of the century. The style of William and Mary, with its trumpet turnings in legs of chairs, dressing tables and chests of drawers (now elevated on frames to

constitute "highboys"), its high curved chair-backs; and that of Queen Anne, with its cabriole legs, succeeded one another some score of years after the advent of these monarchs in England. To this time we may refer the first creation of the American types of Windsor chairs, many of them so different from the English Windsors and owing more to the roundabout chairs. In hickory the Americans found an admirable wood for the bows and spindles. The early Georgian style was adopted in America simultaneously with the use of mahogany, so that mahogany pieces are to be found in the colonies of types which in England were disused before the advent of this wood. Certain types were also created in America, most notably the "block front" secretaries and dressing tables made by John Goddard of Newport about 1763, with alternate projections and recesses crowned by carved shells.

The heyday of the colonial style came in the fifteen years before the Revolution and coincided broadly with the Chippendale influence. Chiefly with the publications of Abraham Swan the forms of the French *rocaille*, with its characteristic pierced shell work, reached America and were used in the adornment of the great mansions of Annapolis and Philadelphia, and such fine houses as that of Jeremiah Lee in Marblehead and Miles Brewton in Charleston, or the Philipse Manor in Yonkers. The delicate carving of the overmantels, with their scroll tops, was matched in the airy relief work of the plaster ceilings. This was the period of the great Philadelphia cabinet and chair makers, such as William Savery, whose earlier work is of a simpler character, Benjamin Randolph, James Gillingham and Jonathan Gostelow, whose workmanship compares with that of the London craftsmen. The most characteristic pieces, distinctively American, are the highboys and lowboys of mahogany, their tops and skirtings carved with delicate shell ornament. The trade of the upholsterer now also flourished; the craft of the silversmith in the hands of such men as Philip Syng and Revere the elder excelled in adaptations of fine Georgian models.

On the eve of the Revolutionary War the influence of the Adam style began to be seen, as in the garlanded ceilings at Kenmore and those executed for Washington after the outbreak of hostilities. The war postponed any widespread effect until after the resumption of relations in 1783. In the following year John Penn, of London, in building his little box, Solitude, on the banks of the Schuylkill, gave the first complete example, and others were furnished in the great Philadelphia mansion of the Bingham and the country seat of William Hamilton, the Woodlands, nearby. The style was introduced in New England by Charles Bulfinch who found an apt follower in the Salem carver, Samuel McIntire. Mantels and doorways were adorned with delicate composition ornaments, at first imported from London, later made also by American craftsmen like Robert Wellford of Philadelphia. Ingenious adaptations of the Adam motives, made with gouge and auger, were widely employed about 1800. Owing to war but little characteristic Adam furniture was made in America, but the developments of Heppelwhite and Sheraton were early and eagerly adopted. The later Georgian models also gave inspiration to silversmiths like the patriot Paul Revere, in Boston, and Joseph Richardson in Philadelphia. Through the new relations with France not a little fine French furniture of the Louis XVI. style was imported to America, as, for instance, by Washington and by such residents in Paris as Jefferson, when American minister, and James Swan of Boston. Both Sheraton and Directoire models were adapted by the gifted cabinet-maker in New York, Duncan Phyfe, whose lyre tables and sofas are among the most refined of American furniture designs. Of this general character must have been the original furnishings of the White House under Jefferson, destroyed by the British in 1814. In the refurnishing of the White House under Monroe, about 1817, it was furniture of the French empire and Restoration which was imported. The heavy mahogany of this classic style with its gilt mountings filled the high, chaste interiors of the American houses of the Greek revival and persisted until the advent of Victorianism.

CHINESE

The Chinese mode of living is quite different from that of the Japanese, though in art and culture the two peoples have many points in common. The difference in the diet and the difference in the style of their dress, manifest themselves in their houses and in their mode of living. Unlike the Japanese, the Chinese house interior is profusely decorated and furnished with chairs, tables, beds, stands, cabinets, screens, etc.

In an ordinary Chinese house the guest room, which opens to the courtyard, has a bare tiled floor, and is furnished with tables and usually 8 chairs. The place of honour in the room is marked by the long table, *kew tai* (bridge table) placed at the middle against the back wall where hangs a painting or a pair of hanging scrolls bearing quotations from the Classics or both. Upon the long table are placed vases of flowers and objects of art. Directly in front of it one invariably finds a square table named, for good luck, *Pa Hsien Tai* (table for the eight Taoist immortals). On either side of it is placed a square stool or an arm chair for the honoured guests. The back wall is often formed of a screen partition, *bing mun*, behind which there generally is another room with a sacred shelf, *sun low*, where deities and the spirit of the ancestors are enshrined high up near the ceiling; and below on the floor a place is provided for the god of the earth, *te chu sun*. In homes of the common people, the sacred shelf constitutes the main feature of decoration in the house, usually occupying the most prominent place above the bridge table in the guest room. In the houses of the upper class, there is more than one guest room or parlour. There is an entrance room, through which the guests pass into the courtyard and into the *cha tai*, a small room where the visitors may change their street attire into a proper dress before appearing in one of the guest halls, *ka dong*.

By removing the *chang chou* (the long windows), the latticed panels between the pillars, the guest hall is thrown open to the courtyard for the entire length. Some homes are provided with another guest hall, *kwa tai* (flower parlour), which may be used for the banquet as well. Whenever possible, the screen partitions (not sliding screens like the Japanese ones) are employed so that two or more rooms may be used as one big room when a large party is entertained. The main wall, as well as the side ones, are generally covered with many paintings or scrolls mounted as the Japanese *kakemono*, which are changed periodically so as to keep them in harmony with the season. In some houses tapestries take their places. The parlour generally has a tiled floor and the bedroom a wooden floor, rugs or carpets being very seldom in evidence even in the wealthy homes, though the country has long been famous for the production of splendid rugs.

The cabinet, tall and dignified, with shelves and chest of drawers inside the swinging doors, occupies an important position in the living rooms of the Chinese house. No less significant is the bedstead, which is often a work of art in its design and embellishment with carvings and paintings. The bedstead usually combines a small compartment to contain a chair and a table. Sometimes the bed is enclosed in a large portable structure with a ceiling, the wooden parts being decorated with beautiful carvings, generally lacquered over. The curtains for the bed, during winter, are of double satin, and in summer either of white taffeta or of very fine gauze, both of which are open enough to permit the air to pass through and close enough to keep out mosquitoes and other insects. The structure is a room in itself, being provided with a door and generally so large that it is fitted with

shelves and contains, not only the bed of ample size, but a table, chairs and a cupboard. The usual furniture is in the dark, heavy, precious hardwood, *tsu-tan*. The chairs with seats of the same material, and backs with an inset of *tai-lee-sek*, marble from Yunnan province which has natural pictorial marking like the paintings after the "southern school," have their simple dignity. Little square stands used for serving tea are often topped with *wan-sek*, the ordinary marble.

Both tables and chairs are often inlaid with mother-of-pearl in floral and bird designs, but the best wood is preferred to be admired in its natural state. Some pieces are lacquered in various colours, while others are lacquered and carved or incised, many of them presenting impelling dignity by their shape, size and tasteful decoration; some of the best examples may be seen at the Victoria and Albert museum. With the massive furniture, heavy carved beams on the wooden ceiling, and panels of latticework that shut off the glare of the courtyard, the room is restful. Superb workmanship in decorative art, with inlay of ivory, coloured horns, mother-of-pearl, etc., on a lacquered ground is shown on the tall folding screens used as partitions in the room. A single-panelled screen, *ping-mun*, also called a devil screen, is placed at the entrance to the house to act as a buffer. While it prevents a view of the interior from outside, it serves to deflect, or ward off, according to the Chinese superstition, the evil spirit.

JAPANESE

The refinement of simplicity, which finds its aesthetic ideal in the natural beauty of materials and is compatible with the austerity of architectural form, is a keynote of a Japanese house-interior.

The Walls.—Rooms of various sizes are made by the use of walls and *fusuma* (sliding partitions of wood covered with patterned or painted paper or silk), running in grooves, which usually measure some 6 ft. in height and $2\frac{1}{4}$ to $4\frac{1}{2}$ ft. in width. *Shōji*, the equivalent of windows, consist of light lattice-work to which is pasted white translucent paper, and also slide in grooves. The grooves run between squared wooden posts, and allow the screens to pass one another, rendering hinged doors unnecessary, and permit of the screens being lifted out altogether, thus throwing a series of rooms into one great apartment. The "filling" (varying in height from 2 to $4\frac{1}{2}$ ft.) between the beam over the screens and the ceiling, is generally, in good class houses, of latticed wood or bamboo or of pierced woodwork called *ramma*. The carving of the *ramma*, often elaborate in palaces and mansions, should be in harmony with the character of the room. Those in certain palaces and temples in Kyoto are exquisitely carved, some having intricate designs in pierced work carved from a single piece of wood, showing flowers and birds on one side and trees and animals on the other, and, in one instance, a flight of wild geese over swaying pampas grass so carved that a painting of the silver moon on the upper wall of the next room may be seen through the openings in the carved *ramma*, beyond the dark silhouette of the carved flying birds.

The Floors.—The floor boards are completely overlaid by *tatami*, straw mats some 2 in. thick and measuring about 3 by 6 ft., each one covered by finely woven grass matting. The size of the room is computed in mats, according to whether it needs $4\frac{1}{2}$, 6, 8, 10, 12 or $12\frac{1}{2}$ mats to cover the floor. In ordinary dwelling houses a room is seldom larger than 15 mats. The spotless matting of closely-woven fresh reeds, bound on the long sides of each mat with a narrow strip of dark linen, together with their pale green colour neutralized by light filtering through the paper screens, and their fresh fragrance, appeal strongly to natives of Japan, and those who can afford it continue to preserve this freshness by reversing and changing the top matting from time to time.

The Ceiling.—The ceiling is equally simple. In an ordinary dwelling house it is about 9 ft. from the floor and formed of thin, slightly overlapping panels of unpainted wood about 12 to 18 in.

INTERIOR DECORATION

wide, whose monotony is broken by parallel strips some 18 in. apart running across the ceiling, and invisibly nailed from above. Since the grain of the wood forms part of the decorative scheme in the interior, the boards are cut from a single tree to insure uniformity. The panels, 6 ft. in length, must be so laid as to suggest continuity of the grain across the room, and must be carefully planed by the carpenter, for they are to be admired in their natural state and no flaw in human handicraft must be allowed to spoil their intrinsic beauty. All the woodwork of the interior must in the same way be left virgin, unspoiled by colour-stain or paint, with occasional exception of the narrow framework of the *fusuma*, and the *tokobuchi*—a piece of wood several inches in width and thickness running along in front of the *tokonoma* (see below) to its full extent—both of which may be lacquered in harmony with *tatami* borders or the *tokonoma* post. This is often made from a tree having some special tint or texture, or else made to conform to its natural curve of growth. A portion of its bark or the worm-eaten marks beneath it, or the stump of a branch or some other witness of nature, is preserved, thus focusing on the *tokonoma*—the most important feature of a Japanese interior—the significance of the design of the room.

The Tokonoma.—This slightly raised recess or alcove, usually built into the wall at right angles to the verandah, is commonly from 2 to 3 ft. deep and $4\frac{1}{2}$, 6 or 9 ft. wide proportionately to the size of the room. In it are displayed the only independent decorations in the room. A painting or a set of two or three *kakemono* (hanging-paintings mounted on rollers) occupy the back wall of the alcove, and a vase holding the *ike-bana* or flower arrangement (*q.v.*), an incense burner or a wood-carving, or some other art object, is placed on its floor. They must each be in harmony with the season or with any special occasion which may befall, and are chosen with a view to give pleasure to an expected guest. There may be many *kakemono* put away, especially in old families, but only one is shown in the *tokonoma*, selected to do honour to the guest. If he is likely to enter other rooms having a *tokonoma*, a distinctive atmosphere must be created in each, while emphasizing some central harmonizing idea. The flower arrangement and other decorative art objects must be complementary to the painting. Thus a *kakemono* of the moon may be accompanied by a few sprays of autumn flowers, artistically arranged in a bamboo basket, and a small bronze censor in the shape of a cottage, thus suggesting a fishing hamlet on a tranquil evening of autumn. Or a painting of a waterfall may hang in the *tokonoma*, while on its floor is placed a rectangular bronze vessel well filled with water and with a few water-lilies appropriately arranged in it. In a small room the same atmosphere may be achieved by showing a narrow *kakemono* of a waterfall in a roughly-executed black monochromatic style and placing on the floor a single white blossom of *Hibiscus mutabilis*, half-concealed among its freshly moistened leaves, displayed in a slender bronze vase with very cold water so that the moisture collects outside and trails down over the beautiful patina, creating the suggestion of a miniature pool on the round flat lacquered board of liquid black upon which the vase stands.

Thus the guest is brought to feel the very spray from the waterfall, transforming the confined room into a fitting place in which to entertain visitors on the hottest of summer days. An alternative to the painting is a couple of lines of poetry on which the guest may meditate on his entrance into the room. His attention may next be led to a *bon-seki* (*q.v.*), a tiny landscape contrived with natural stones and sand, on a black lacquered tray at the foot of the *kakemono*. It may call to mind some familiar scene—a rocky promontory with an island near by, and beyond the moonlit sea the dim contours of undulating hills. The poem on the *kakemono* (for calligraphy is also treated as a pictorial art) thus quickens with new meaning for him and he can share the poet's inspiration.

Other Decorations.—In a companion recess adjoining the *tokonoma* are *chigai-dana*—shelves arranged stepwise—for additional art objects and there is usually a small cupboard with appropriately decorated sliding doors either above or below the shelves. There may also be a low writing-place built at the side

from which the light comes, in front of the *tokonoma*, where lacquered boxes for paper and other writing paraphernalia can be placed, further decorating the room. What articles, and how and where they are to be arranged in these places to conform to the general scheme and to afford the maximum of decorative value and aesthetic pleasure, has been an aesthetic study for centuries. In the time of the Shōgun Yoshimasa (1444–73) a set of systematic rules of decoration had already been formulated, and is still followed by some of the "tea-men." There may also be placed by the low writing-table in the master's room, a portable lacquered set of shelves or a cabinet carrying a few objects of art for his delectation in moments of leisure.

Thus simplicity of display is fully compatible with wealth of possessions. The same object is rarely seen twice in a dozen visits. Hundreds of beautiful things may be stored in the treasure-house. Guided by his knowledge of the character and temperament of his guest, his recollection of the impression made by the things on view on former occasions, a Japanese host will select from his store, always aiming at giving pleasure and a delightful surprise to his guest.

Sometimes a skirting of strong white or grey paper about a foot high as a protection against the broom is seen on a Japanese wall, but it is never papered or covered up by paintings, although a *gaku*, consisting of a painting or a few written characters expressing or suggesting a poetical sentiment or a truth may be framed above the *fusuma*. Plastered earth and sand, variously coloured, and mixed with boiled *funori* (*Glipeltis furcata*) to give solidity, is used for the interior surfaces of the lath and plaster walls, and the pounded shell of little fresh-water bivalves or iron filings is sometimes mixed with the sand for their decorative value. Plaster in tint of smoke, mist or cloud, often has a hard and resistant surface.

Furniture.—In the Japanese house the furniture is conspicuous by its absence. There is neither table nor chairs such as are used in China or in the West. Everybody removes his or her shoes, sandals or clogs upon entering the house, and even slippers or house sandals are left outside in the wooden corridor. People sit, or rather kneel and sit back on their heels, on the *tatami* on flat square cushions. Each person is provided with a *tabako-bon* (smoking set) in summer and a *hibachi* (charcoal brazier) in winter. In some houses to-day gas or electric stoves are fitted, but the brazier is the characteristic means of warming a Japanese interior. It may be of bronze, porcelain or wood decorated with lacquer, and is furnished with a pair of small tastefully designed and ornamented fire-irons like chopsticks. Braziers are usually small and portable.

Beds may be arranged on the floor in any room at night by piling up wadded quilts, which are folded and packed away in the closet, after airing in the sun, in the morning, leaving the room clear for other uses during the day. A *tansu*, a chest-of-drawers in plain paulownia wood, may betray the sleeping apartment, but this, too, is often placed in the closet, shut off by *fusuma*, so as not to be seen. A clothes-horse is as a rule also placed out of sight behind a screen. *Byōbu*, ornamental folding screens of 2, 4 or 6 panels decorated with writing or painting, or carried out in plain gold, serve many a convenient purpose, warding off draughts or hiding an undesired view. A single-panelled screen called *tsuitate* is usually placed in the entrance-room, to allow of the front *shōji* being pushed open without exhibiting the interior of the house to a caller. Even the dining-room is without any sign of its use, a collapsible low table being brought in for family use at mealtime, or food being carried in and served to each individual on small low lacquer tables called *o-zen*, kept in the kitchen cupboard when not in use.

In the summer heat the ordinary *fusuma* and *shōji* are frequently removed and replaced by others specially made of rushes or split bamboo to permit the passage of any breath of wind that may happen to stray into the house. The floor, too, may be covered over with rattan matting, to impart coolness; and *misu* or blinds made of split bamboo or rushes, may be suspended from the eaves to give shade and privacy.

Simplicity the Keynote.—Japanese rooms are thus extremely

simple, though neither barren nor cheerless, since every detail of form and colour is studied and harmoniously combined, even the joinery being so perfect that not a trace of a nail can be seen anywhere, with the result that, at least for beauty, the empty room is sufficient in itself. There is a sense of relief in this absence of furniture. These neat and airy rooms, so restful and so spacious, may be opened at will for their entire width onto a tiny landscape over which the eyes delight to wander. Or they may be closed up completely, leaving the occupant alone with an iron kettle (an object of art in itself) gently boiling on the charcoal fire, overlooked from no window, but accompanied by the silhouettes of bamboo or pine branch in the garden forming countless attractive patterns on the creamy paper of the *shōji*. In such a room may be admired an ancient tree of stately form, growing in a pot placed in the *tokonoma*, and still retaining its dignity in its miniature form. Freed from the distraction of furniture, the men and women in the room recapture their dignity and significance. In the simple form in which the exigencies of construction determine the refined and reserved quality of the decoration, and the furnishings are reduced to the essentials, while the subtly blended colouring and the constant variety of the view on which it can be made to open build up a composition of delicate lines and graceful forms, the Japanese interior well fulfils its main and consciously recognized functions: it supplies an appropriate setting for clean and simple living. MODERN

Any consideration of the principles of interior decoration as determined by modern needs should contain a comparison between the work of past periods and that of our own. Sound development does not lie in a mere production of novelties; the whole circumstances of the age must lead in a natural line to the new form. We know that the mentality of our ancestors up to the beginning of the 19th century was unblushingly feudal and that comfort itself was sacrificed to the ideal of magnificence. Anybody with any pretensions had to be magnificently dressed, and his personal status was indicated by a suitable uniform, with abundance of gold, long tassels and richly-chased arms. Obviously the rooms in which these men lived had to be equally magnificent. Tradition, assured culture and discipline, combined with great naivety, made this possible. We can still imagine to-day that the craftsman found salvation only in producing work of the best possible quality; but unfortunately we have no conception left of how it was possible to make him so happy that he produced one new form after another, with amazing power, and how he was able, without any serious friction, to carry all his contemporaries with him and, lacking all the enormous modern facilities, yet to spread his ideas throughout the whole civilized world. The age which followed gave the bourgeois its chance, and simplified everything; the form aimed at was more severe, but despite this limitation there was an increase of refinement, and a great and sometimes fantastic, but suggestive multiplicity of design appeared. This phase ended in Europe about the middle of the 19th century, and was succeeded by a dreary, generally mistaken imitation of earlier styles, intolerant of all else, and fatal to all genuine tradition; corrupting work and making it superficial, and leading at the best to falsification. Although the modern man is changing completely in externals, concentrating increasingly on practical matters, and would certainly not dream of appearing in the street dressed up as a knight, in the decoration of his home he thinks it necessary to copy some form of decoration belonging to the past: In this way he loses all feeling for real development and, through his art studies which are generally superficial, loses all touch with living art. Work is mostly performed by machinery. The engineer is preoccupied with his constructive, calculating methods; nothing is sacred to him; he can make anything to order; and the products inflicted on us, the cast-iron stoves, benches and furniture, the first motor-cars, the pots and pans and small artistic products with a superfluity of decoration in every style, the Gothic not excepted,

have accustomed the great, ever uncritical majority to buy the most hideous objects with indifference, and to lose all sense of natural beauty and of individual form. This process has been carried so far that business men have made serious good work impossible through their so-called "cheap goods." People with taste draw back from all this and collect antiques and generally end by forgetting that it is their duty as it was formerly the duty of the court, the nobles, the Church, and later, of the educated classes, to foster a high standard of art and craftsmanship. The modern movement has begun by realizing this and by searching for a way out. Ruskin and Morris both sought to awaken humanity to the beauty of good craftsmanship and genuine material, and gradually introduced old techniques and methods of work. As a result of their teaching wonderful works in metal, leather, ceramics and textiles were produced, but were often created in by-gone styles, although freely adapted. Ashbie, in 1885, went farther, and produced in the Guild of Handcraft excellent modern silver work—although again in antique form; the development of the art of the Scot Mackintosh into a wholly new, original style is amazing. His rooms in pale grey wood and violet struts and embroidery adorned with rose-red flowers, his original lighting and glass, his heating apparatus, indeed every detail, were remarkable and full of promise. Innumerable forces bestirred themselves, seeking to evoke, in England first, then in Holland, Germany, Austria, France and the Scandinavian countries, a great, genuine and creative artistic movement, to help the world to reach again a unity of culture. At first there was no radical transformation. The business interests were alarmed, disconcerted, and, without established precedents to guide them, were quite bewildered. The public also was wholly bewildered, in part enthusiastic, in part misunderstanding and prone to severe criticism.

Yet the movement, which ended with the beginning of the war in 1914, succeeded in making itself felt everywhere. To-day we are confronted by a movement which is even stronger and obviously more radical than before, which has learnt in the hard school of war and poverty which followed it many a lesson which the great public needed and was bound to receive.

In modern interior decoration, now that it is recognized that decoration alone, even new forms of decoration, admittedly does not create style, the great need is to have a complete apprehension of the task in all its essentials. We no longer think in terms of pillars, window-frames and decorations of one type or another; we create the room to be the environment of some particular human occupation, adapted for that purpose, simple and concise in form, and constructed in the best and most suitable materials. Manifold needs give birth to equally manifold expressions and we are beginning to construct with comparative certainty, without the risk of committing blunders. A city of to-day looks quite different from the city of a hundred years ago. With the help of new technical contrivances we can achieve quite unprecedented effects, because our first care is to apply all the methods of sanitation, to preserve correct proportions in design and to consider the needs of every class of society. In a modern house bacilli lead a sorry existence; light and air flow through every corner and cranny. Glass, manufactured in every possible way, set in metal, to economize space on the frames, is replacing white walls. We attach the chief importance not to the lighting apparatus but to the light, and similarly we care more for the heat than for the heating apparatus.

First consider the living rooms. The size and height must partly depend on circumstances; the height must not be less than 7 ft. 6 in. to 8 ft. 6 in. One wall—facing east, south or west should be glass from ceiling to floor; many rooms, such as the breakfast-room, winter garden, living rooms and day nurseries may have two or even three sides of glass. Double glass, reaching to the floor and lined with water-tight material, may provide a space for flowers, plants and perhaps statuary. Besides having a door in the inner glass wall there could be a second door in the outer glass leading on to a balcony or a terrace. There should be no pernickity curtains, blinds, etc., but some suitable means of protection against excessive sun. In first class work the actual wall surfaces are sometimes left without further treatment with fine effect. In rooms already built and wall surfaces already treated, it is

necessary to treat the wall aright, making it either washable or porous, according to how the room is to be used. As room space is usually scanty, we cannot have walls which will be too easily damaged or stained during occupancy. The whole wall treatment, up to the ceiling, should be uniform. Above all, there should be no wainscots. Wood panelling is highly effective—choice woods, beautifully grained, the doors not unnecessarily large, and unframed, and simply cut out of the wood. In small rooms the ceiling also may be executed simply in wood, a treatment which gives a good, severe, solid effect. Parquet floors, covered with self-coloured linoleum or with loose carpets are often desirable; carpets are needed where the occupants are likely to spend long hours comfortably seated at ease. The carpets might be self-coloured and of good material; if they have broad or narrow stripes of dark colour marking the border, they look well and will certainly never be thought tasteless. Whatever cupboards are required in such a room should be built into the wall, and writing-tables, etc., should be made to tilt up and disappear into the wall. Collectors will perhaps add glass cases, reaching to the ceiling, to these walls, and may even keep pictures in this way; for to use valuable pictures or statues as wall decorations is dangerous to occupants and the safety of the pictures or objects.

Heating and Lighting.—The approved method of heating to-day is by hot-water pipes, which give a fairly certain and regular warmth. As they require large radiating surfaces, on account of the not excessive warmth they impart, they might also be built into the lower parts of the wall—suitably isolated, of course. Light is best admitted through the window, hence this should be well lit up in the evenings also—perhaps by ceiling lights between the double glazing. This form of illumination will usually suffice, but a number of contact points at carefully chosen places, including some in the floor for standing lamps, etc., of the most varied types, will prove serviceable. The age of pompous lamps and chandeliers, etc., hung from the ceiling, is past; they break up the space and blind the eye. It is important to note that candle-light burns upwards, and does not dazzle if the brilliance is not excessive. It was natural and necessary, in an age of magnificence, to assemble countless candles in a cluster; the flickering light, surrounded with polished crystals of glass, was capable of producing great effects. The form of illumination produced by imitation candles of frosted glass and electric lamps in the shape of flames—a lifeless copy—is one of the most incredible blunders in taste. Gaslight, as an open flame, or better, with mantle, also burns upward. Its characteristic mark is the supply of the fuel by means of pipes. The pipes must therefore be given special prominence. Electric light is used in incandescent wires; its characteristic note is that it hangs downward, and on a cable. This is the proper position of an incandescent lamp, and it is an abuse to place it sticking upward, for the sake of some favourite lamp. The modern age of incandescent lamps offers the most varied and original combinations and will prove particularly serviceable in public localities and large apartments. The candle continues and will continue to be employed as a table illumination at meal-times, on account of its comfortable, and at the same time decorative effect. (See LIGHTING AND ARTIFICIAL ILLUMINATION.)

Colour Treatment of Walls, etc.—In deciding on the wall treatment of a room the governing factor is always its purpose or use, which should determine its form. In many rooms which are only meant to be occupied for short periods, and are made of masonry, the colour of the paint, in particular, can work wonders. A beautiful bright cinnabar red, pale yellow or green have a cheerful effect. A deep red will certainly have a solemnizing, pale blue and grey a tranquillizing, effect. Very light brown, pink or pale violet are generally suitable for ladies' rooms. Blue is a very good colour for resting rooms and bedrooms. A white wall, as such, in a beautiful, natural material, will always remain in favour, and will invariably prove a good convenient background for furniture and stuffs. In considering any other colour, the chief point is whether a warm tone (yellow, brown, red) or a cold one is required. This is where most mistakes are made; a very strong sense of colour is necessary if the whole effect is not to be spoiled by woods and stuffs which do not harmonize in colour. A new idea,

which conforms with our feeling for space, is to put slashes of the colour of wall and ceiling on to the window wall. If we put in any exceptional piece of furniture, part of the wall, against which it stands, can be coloured to suit. It will sometimes be admirable to cover walls and ceiling altogether with stuff, giving an effect of warmth. It is preferable to do this first with stuffs in a single colour.

Disposition of Furniture.—We shall, then, need less and less furniture in our living-rooms, since everything put there merely for show, or, worse still, for symmetry, must vanish. The fireplace, burning wood or coal, should be retained on account of the ventilation which it affords, of the beauty of the open flames, and of its warmth in autumn and spring. The inmates of the house will love to gather round it of an evening, or in chilly weather, and this is the chief place in which seating accommodation, of varying size and shapes, is to be placed. A low occasional table, always placed beside a chair, never in front of it, and electric lamp, and perhaps a small moveable stand for books, newspapers, and possibly light refreshments, will meet all needs. As most, if possible, all articles of furniture should be fitted into the walls, we hardly need any more furniture in the living-rooms beyond chairs and tables, except perhaps a flower-pot for a beautiful, large indoor plant. The latter should preferably be a lime or an oak, rather than a palm or anything else alien to native flora. Cut flowers in a beautiful glass or a good piece of pottery, set in the right place, give great pleasure. The first law of the decorative artist is to make life cheerful and full of joy by the simplest possible means. The time is gone when human beings were supposed to find pleasure in dark, cellar-like rooms with heavy carpets and festal plush curtains, innumerable ugly knick-knacks such as balustrades, candelabra without lights, flowers with artificial dust to imitate the genuine, wardrobes and chests of drawers.

Bedrooms and Bathrooms.—The bedroom must be light, again with one wall all windows, the beds on simple stands of wood or metal, not unnecessarily large. The light must be behind the head, so that one can read easily, lying on either side. A roomy easy chair with a small table beside it, a footstool, small, light tables on either side of the bed on which to place books, medicines or a glass of water, will be sufficient furniture, if we have made arrangements for everything else in the bathroom and dressing-room.

The bathroom has become increasingly important. It is impossible to do without it, and for various reasons it is desirable to allow it ample space. It is used, not only for washing and bathing, but for gymnastics and massage and all sorts of exercises. It must allow of quick and thorough cleansing; both walls, floor and ceiling should therefore be tiled. Furniture, if any, should be of enamelled metal glazes, as in the operation room of a hospital. The walls and ceiling may, of course, also consist of enamelled metal glazes, and the colour, besides white, a very pale grey, or, for a lady, even a pale pink shade. The dressing-room may have cupboards for all purposes around three walls, with one wall wholly mirror, in front of which should be a small table for toilet articles and the like and a low, wide chair, painted in dull oil or varnished. The lighting should be built into the mirror wall on either side, the floor covered with heavy mats or carpets, as it will often be trodden by bare feet. It should be possible to see that the floor of the bathroom is warm, not ice-cold, without employing bath-mats. In small houses, however poor, at least a sheltered table-nook must be arranged.

Attics, Kitchen and Pantry.—The attics, kitchen and pantry, the latter next to the dining-room, should also be clean, easy to wash, and in every way practical in their arrangements. No machines or implements whose shapes are in any way decorative or ornate should be used. The stands for kitchen utensils should be open, the lighting from the ceiling, which, like the walls, should be covered with simple white, undecorated tiles. The floor should be paved with plain slabs, preferably in pale grey or black. Pans, jam pots, etc., are better put away in a separate niche than in a refrigerator.

Assistants must be trained to look on themselves not as servants but as colleagues. They must be lodged in a nice, cheerful room

and have their own recreation and dining rooms, to avoid any feeling of inferiority. It is advantageous, if only on practical grounds, to have each of these rooms in a different colour. Obviously there must be ample facilities for bathing and washing.

To turn to the nursery, it is well to separate the day from the night nursery. Where there are many children, a sickroom with all modern comforts would be very desirable. In the day nursery everything which might cause injury, such as sharp curves and angles, must be avoided. Special regard must be paid to the childish habit of crawling about. Tables should be round and the edges of the surface and the feet rounded off. Toys may be kept in cupboards which can be opened easily and without danger. Walls and ceiling must be in bright colours, perhaps each with a different colour, red, yellow, green, white, the ceiling light blue and the whole decorated with small stars. A convenient low chair for the mother or governess is an absolute necessity: the cover should be bright stripes, of washable material; the lighting again from the window wall and with convenient contact points for a portable lamp. Contacts for a wireless and cinematograph also must not be forgotten. A small darkroom for photographic purposes is desirable. In large houses a small workshop might be fitted out for the boys, to arouse their instinct to use their hands at an early age, and have a place where small repairs can be carried out.

Furniture and Craftsmanship.—The furniture in the living-rooms should be chiefly of walnut and oak, and in countries with colonies, also of foreign woods such as mahogany, etc. Dyeing and staining is out of date, but inlay work, carefully prepared and used in dry rooms, has proved its value. Deal is very suitable for bent wood furniture, which is made in the following way: the wood is cut into strips, which are put into metal frames, through which steam is forced at very high pressure. In this state the wood grows so soft that it can be bent into any desired shape. This kind of furniture is often employed in offices, cafés and similar establishments for which its extraordinary cheapness, which can yet be combined with excellence of shape, fits it. Naturally, wherever possible, any other kind of wood may be employed if obtainable and suitable for this purpose. Nowadays metal is also often used, both bare and enamelled or painted. Abstinence from the use of machinery in making furniture, as required by Ford Madox Browne in 1881, is no longer practicable. The machine should be used simply as a tool; and under no circumstances must it imitate handwork; it should be used only on work of the type which demands no artistic impulse; e.g., the pressing and filing for inlay work under steam pressure, the trimming and preparation of the material, etc., operations which will not distort the craftsman's work; the machine is there to save time and labour. Any unintelligent work can be replaced by the proper appliances. The shape produced by machine work must be quite distinctive, to allow a proper appreciation of its peculiarities. It is certainly wrong to make use of machinery to produce large quantities of ugly objects, with its accompanying waste of material. It is not absolutely necessary for us to produce everything by handwork, nor is that the sole criterion of value, but it is absolutely necessary that machine productions should be well thought out—high-minded, in fact, but not deformed and obscured by unsuitable decoration. An inventive brain and good planning and design will always re-discover beautiful form. Detection of servile imitations will always allow real talent to accomplish work of value. This point is of the greatest value even from the economic point of view, when we consider that even to-day in many countries, valuable material is rendered valueless by bad workmanship, whereas right treatment could only enhance its value and so make life more precious and sanctified. Only beauty, beauty everywhere, can further exalt our modern life and make us happy. There ought to be a movement, similar to that of the Church, to follow these ends and declare war on all bad methods of work. The great talents many of which live and perish to-day unnoticed would suddenly awake to life and create works of undreamed-of grandeur, as of yore. It is this spirit, together with a universality of understanding and co-operation, that is the great lesson of the past; not bad imitation, which inhibits and destroys fresh ideas. The fact is that to-day we in Europe no longer have any

conception of the mysterious forces of the old workshops, which yet produced work that was always good—sometimes outstandingly good. What was the social position of those men in comparison with the organised world of to-day? Our chief interest lies in the men who lived and worked in the period between the great migrations and the mid 18th century. How could that extraordinary unity arise between palaces, castles, churches, city halls, even whole cities and whole villages—a unity complete down to the smallest detail, and crystallising into clearly defined styles? Art follows no law. It can only spring from deep spiritual movements, and the greatness of it is the mirror of the greatness of an age. It penetrates into the smallest mountain hut, whose simple, unsophisticated shapes are equally a reflection of the spirit of the age. To-day we are learning to appreciate increasingly the unsophisticated work of these simple men; it is a revelation to us, as is the work of the modern child. The essential in old times lay in the wonderful work fashioned by master craftsmen in excellent workshops. It may have been the year long community in work and creation. The blossoming of childhood in good surroundings. The complete mastery of the handicraft and the joy of producing something ever new, ever more fully perfect. The only external impulse in those days came from strange pieces of booty brought home by knights from the wars, and through the co-operation of masters who had been carried off in captivity. These masterpieces blend in natural wise with the native works, and new, mysterious creations issue. In those days there were no workmen, only masters and apprentices. The work, design and execution, sprang from one force and was therefore created with a love unknown to-day. Based on a great tradition swayed and inspired by universal sympathy, men were ever inventing something new, either in form or in better work, striving towards the highest perfection. The clumsy apprentice was mocked and cast out, the skilful admired and encouraged. To watch the life of his fellows from childhood in the workshop was for the layman the best education, to train him to become a true and appreciative connoisseur.

There may still be workshops of this sort to-day; the tailor's workroom, perhaps, comes nearest to it. Let us consider a moment where their true value lies. Something is sewn, for example, with a machine invented on the grand scale, superior to handwork chiefly in accuracy and regularity. Superior except in one point, the feeling for material. Once set-in motion, the machine can only work on mechanically, and so must fail wherever attentive hand-work, inspired by mind and feeling, takes account of every difference, however small, and thus gives even greater steadiness, being therefore better in quality and so also creating greater value.

Complete recognition of the task and unshrinking performance of it must lead to a new style. While the first necessity is the simple, unadorned form, we need have no fear of genuine talented enrichment. Talent will always find the right way by instinct, and need not shun the most complicated shape. Finally let it be said that where for any reason a richer shape is preferred the forms created must always be new and natural. Repetition of old forms, old styles that have already had their day, is simply ruinous. It is equivalent to a confession of poverty of ideas and destroys all natural understanding and enjoyment. At the Congress of modern bridge building in Vienna, Sept. 1928, the president, Dr. Otto Linton, of Stockholm, treated this question at length, declaring that the architect was now a back number, and had been replaced by the engineer. He sees in the architect, the decorator who sticks pointless rosettes into purposeful building—a misrepresentation of the artist's real rôle, which consists in giving expression to the requirement-plan, and order to the purpose-form. He will always find aim and purpose for his work in satisfying fully the needs put forward by the builder, think in good proportions and rightly chosen material and express himself through these, and not through ornaments stuck on at random.

Style cannot, as Linton says, be dictated by the brain of the mathematician or the blue pencil; it springs from the character of a nation. The determining factor is whether that character is natural or corrupt, crude or refined, and whether it has advanced to the stage of seeing and preferring the better. It will never

be possible to make exact calculations regarding colour, and yet colour is one of the most important factors in modern building and decoration. It would be equally foolish to say that artistic painting is a back number to-day, varnishing and distemper alone required. The only true measure is to appreciate the value of modern painting, feel its quality and estimate that alone. The essential is not even the individual species within modern painting—although this, too, certainly needs to be considered, but solely the significant side and special quality within a capability. We see this best in photography, which can be splendid or absolutely uninteresting, according to the amateur who handles the camera. The main point is therefore to re-educate ourselves so far that we can choose the right forces in every field and allow only great capacities to influence us. The more true forces assert themselves, the higher will be the cultural level of a people. The work of the engineer is much less cramped than that of the architect, hence his untiring development, particularly in all creative fields. Respect for the achievement is still intact, and the success is consequently greater.

Business Premises.—In fixing our business localities, consideration must be paid both to absolutely economic and purposeful arrangement and also to advertising effect. The principal problem is again that of material, colour and lighting; but the wares on sale must also be good.

As for the cinematograph, the first requisites are good, comfortable seating accommodation and easy entry and exit. Tip-up seats covered with good leather, a good carpet on the floor (if possible of the same colour as the leather); the walls preferably hung with stuff, and similarly all curtains, partitions, etc. made of the same material, will give a good effect. An efficient system of ventilation and perfect lighting (*q.v.*) (preferably by means of soffits), for the intervals, is required. Particular attention must be paid to the vestibule, as this is very much used. Marble or inlaid wood are both suitable materials. If the till and the buffets are made automatic, great simplification in running will result. If the rooms are given convenient shapes, the staff can be reduced. In cinematographs and the like special attention must also be paid to securing the electric cables. They are best laid in the walls; but it is advantageous for the purpose of repairs, to have them easily accessible. The cables must therefore either be laid in grooves in the walls, or stretched free, absolutely taut; for the frequent, untidy crooked laying and fastening is dangerous as well as ugly. Absolutely perfect fixing is the first duty. The last word on this point has not yet been said. It is best if the cables can be fastened without visible screws, for screws are always a makeshift. Otto Wagner declares permanence to be the first law of all architectural expression. This calls for good material and excellent work well planned and designed. To achieve this, requires constant practice and the possession of a natural capacity of identifying oneself with one's task. For example, in decorating and fitting a butcher's shop. Our immediate thought is to cover walls, ceiling and floor with a material which will keep cool and can be washed, therefore tiles are used. In old days we should have wanted to adapt it to Roman precedents; to-day we invent good fittings, avoid all ornamentation, but put the signs in the right place, and in perfect lettering. The lettering, which is usually a disturbing element, has assumed particular importance to-day.

There have always been certain objects which accurately reflect our age, and a later age will find it easy to recognize in these the forms in which we express ourselves. This is especially relevant to the coach-work of motors and modern carriages, rolling-stock, aeroplanes, etc., and many machines, if designed solely to express their purpose and not marred by antique decoration. The arm-chair, too, has been altered and adapted to suit modern requirements, solely on practical grounds. The interior fittings of many theatres, hotels, restaurants, cafés, cabarets and bars must be described as quite new and successful. The equipment of ocean liners, especially in the working parts, is also modern, even though here, as with the American sky-scrapers, an absolutely modern construction is often spoiled by incomprehensible, antiquated decorations.

Materials and Ornaments.—We must emphasize the value of

the material itself. We should never think of decorating a pearl; similarly we should consider carefully to what purpose we should apply materials. Under no circumstances whatever is imitation permissible. The use of linoleum, for example, is an admirable thing when it can be obtained in self-colour or in a pattern which suits the material. As soon as it begins to imitate veining, it becomes unusable. When linoleum is used it is best to employ a light, grey, even tint. Everything is an appliance for the use of the modern man, and must consequently, logically, be made to fit modern clothes.

In 1843 Rossetti founded the pre-Raphaelite Society in London; in 1881 Monos and Co. was founded. New stuffs, carpets, books, book-bindings and furniture were related. In 1881 the workshops were removed to Morton Abbey in the South of London.

In 1883 the Art Workers' Guild was formed, which began to hold the Arts and Crafts Exhibitions in 1888. In 1885 Ashbey in England founded the Guild of Handicrafts with Baillin Scott in Essex House. On the continent the chief experimenter in a new style of building was Berlage in Holland. His Bourse is a milestone on this road. He was principally interested in building with raw brick, with concrete facings. I. B. van Loghem, I. P. Oud and Jan Wils, architects chiefly concerned with utility buildings, were the leaders in this field. Van de Velde in 1914 built the tripartite theatre at the Cologne Theatrical Exhibition. Sweden produced, among other buildings, the fine concert hall of Tengborn. In 1898 Olbrich built the "Secession" in Vienna, in 1904 Otto Wagner constructed the Post Office Savings Bank. In 1903 the Wiener Werkstätte were founded, and in 1905 the Stoclet Palace in Brussels built. In the German countries the "Werkbund" movement arose, and schools were founded everywhere in the many large towns which spread like the new intentions. Peter Behrens erected the offices to the Allgemeine Elektrizitätsgesellschaft in Neubabelsberg, near Berlin, in 1917, and a turbine factory for the same company. Still earlier, in 1910, Hans Pölzig had built a factory in Luban, near Posen.

The intention is to do justice to the construction and accommodation, to avoid all statistic forms and simply let the construction speak for itself, the chief stress being laid on well-chosen proportions. Fahrenham in Düsseldorf, Pfeffer and Mendelssohn in Berlin go further, and prefer a richer style for internal accommodation. Bremono Paul and Arnold Nechansky have also created rich and original interiors in Charlottenburg. After the war, the whole trend was towards greater simplicity. Walter Gropius in Dresden built solely in concrete and glass. He constructed the Stadttheater in Jena in 1922, the Baerhaus in Dessau in 1925. W. M. Dubok, of Hilversum, Holland, built the school at Boschrift on three lines in 1922. To the same school belong also the designs and buildings of Corbuisier and Pierro Jeanneret in Paris, Miles van der Roho, Bruno and Max Taut in Berlin, and the works of Freysinnet, Mallet-Stevens and Chaneau in Paris. The arrangements of the Stuttgart settlement in 1927 give a good indication of the new projects. The chief authors here, besides Gropius, are Corbusica and the Viennese Josef Frank. The most grandiose achievement is the Stuttgart railway station, together with the festival buildings in Salzburg by Behrens and Holzmeister. The buildings and decorations of the exhibition on the "Pressa" in Cologne in 1920 and the Düsseldorf Art Exhibition give a true picture of the whole development. In America the leader is Frank Lloyd Wright, who has been following the same path for 20 years. Many utility buildings, such as the imposing granaries in Montreal, and others in South America, are completely satisfying. The sky-scrapers are unluckily marred by unharmonious architecture; on the other hand, a granary of the Washburn-Crosby Company, built in Minneapolis in 1920, is an absolute model.

The collections of stuffs and wall-papers in the Wiener Werkstätte and the Deutsche Werkstätte show patterns which are original and usually successful. Good and successful work in lace, embroidery, carpets and tapestries can also be found everywhere. The treatment of metal has also made extraordinary advances. Angela Stodthen's room, of pure beaten copper, in the Austrian pavilion at the International Arts and Crafts Exhibition of 1925

in Paris, is an example of this type of work. Similarly, ceramics has developed greatly, and plays an important part in fireplaces, wall-decoration and above all in frescoes. The free painting of walls, particularly in restaurants, cafés and similar localities is also much in use, but fresco-painting is also often successfully employed. (See also RUGS AND CARPETS; LIGHTING IN PRACTICE.) (J. Ho.)

WALL-PAPER

Paper wall-hangings were first invented as inexpensive substitutes for the costly and sumptuous hangings of brocade, brocatelle, tapestry, stamped leather and Genoese velvet, used in the palaces and the great houses of Europe in the 16th and 17th centuries.

The earliest beginnings of this art are still in some obscurity. It is evident, however, that printed wall-papers were not made until after the discovery that type could be cut on wood-blocks and printed. Apparently some of the earliest paper wall-coverings were produced by the letter-press printers themselves. This fact is substantiated by a discovery made in 1911, during restorations to the entrance hall of Christ's college, Cambridge. On the original beams of the ceiling, in the entrance hall and dining room, was found the oldest block-printed wall-paper known to be in existence. The design is in black and white, done on the reverse of the proclamation of the accession of Henry VIII. Scarcity of good stock evidently led to this economic use of both sides of the paper. The pattern is that of a contemporary velvet or brocade. It is signed with "a great H and a goose," the mark or rebus of the master-printer, Hugo Goes, who was living and working in Steengate, York, in 1509.

Domino Papers.—But the real development of the wall-paper idea is due to the *dominotiers* of France, a group of men working in the 16th century in Rouen and other cities of the provinces to make domino papers and marbled papers, which were eagerly bought by the peasants as a decoration for their fireplaces. Undoubtedly this inspiration came from the decorative Italian papers used to line boxes and books. The Frenchmen, however, were the first to put such papers to general use as wall-hangings.

Domino papers were printed with little geometrical figures, designs in compartments, or grotesques. Marbled papers required no printing, but were made by floating off the colours from the surface of water, after "combing" them into various marble designs. Both domino papers and marbled papers were also used in France for end-covers of books, and for covering or lining boxes. Special marbled papers in black and white were made for funeral prayer-books and other mortuary requirements.

By permission of the king, the *dominotiers* merged with certain wood-engravers in 1586, and formed a corporation or guild of "*dominotiers, tapissiers et imagiers*."

Small sheets of paper like those used for the *Images d'Épinal* (c. 12×16 in.) were employed for these paper-hangings, which were sold by the quire or by the ream. The outline of the design, engraved on wood-blocks, was printed by means of a simple

press. The design was then coloured by hand, by means of stencils, using distemper colours mixed with glue. The French name of *papier peint* for wall-paper is a descriptive relic of this early process. No attempt was made in these earliest wall-papers to arrange designs in such a fashion that they would match when the small sheets were put together on the wall. It was not until the master *dominotier*, Jean Papillon (1661–1723), invented continuous matching designs about 1688, that people were relieved of the casual effects created up to that time whenever wall-paper was used.

Jacques Chauvau, who was a pupil of Papillon, improved on his master's ideas by printing all the colours from successively applied wood-blocks instead of stencilling them by hand. He had great success from his initiative; his method was quickly taken up by Boulard in Paris; and papers of the same sort were soon printed in Chartres and in Orléans. During Papillon's time the popularity of wall-paper increased. Savage opened a factory in Reims; Le Tourmy and Rabier-Boulard had wall-paper factories in Orléans; Isnard of Strasbourg, Descouteaux of Chaumont, Vautrain of Nancy, and Roche of Lyons became well-known for their work in engraving and printing paper-hangings. The new technique of printing in colour was not universally substituted for the old. Until the end of the 18th century, there were still small ateliers that remained faithful to "illuminated" papers. Nevertheless the process was widely used.

Both paper-printers and paper-hangers had been greatly handicapped up to this time by the fact that they were obliged to work with small-sized sheets of paper. In 1760 Fournier, a merchant on the rue Carré St. Martin, Paris, made the first attempt to produce paper in long strips by pasting the small sheets together before printing, thus forming a roll. An edict of Louis XVI. in 1778 decreed that each such "roll" should contain 24 sheets of paper, pasted end to end, making the length about 34 feet. The name and address of the maker was obligatory on the two end sheets. This was the standard size for a roll of wall-paper until the metric system was adopted.

Flock Papers.—The discovery was made in 1620 that chopped wool could be used to produce wall-paper which resembled velvet and tapestry so closely as to deceive both the eye and the fingers. This new invention, especially suited to contemporary fashions in house-decoration, was launched by Le François of Rouen. His process was very simple. Instead of the ink or distemper colours used by the *dominotiers* for printing their wood-blocks, he employed a mordant or greasy varnish. Before it dried he shook or blew over it, by means of small bellows, very finely chopped wool in different colours. This substance adhered to the varnish and covered the design. The superfluous wool was then shaken off, and a perfect imitation of brocaded velvet was obtained.

The cost of flock papers was small, in comparison with the sumptuous stuffs imitated, and their effect was so impressive that they attracted great attention and made the name of Le François famous in all the countries of Europe. Jerome Lanyer, of England, was inspired to attempt the same process under a grant made by Charles I. in 1634, giving him the exclusive right to manufacture flock hangings which he called "Londriniana." For this privilege he paid the sum of £10 a year to the crown. Lanyer's flocks were made, however, on "linnen, cloath, silke, cotton, leather and other substances," probably because there was not at the time any English-made paper strong enough to use for the purpose.

Fifty years later Dunbar of Aldermanbury was advertising an amazingly large assortment of flock papers, "some after the manner of real tapestry, others in imitation of Irish stitch, flowered damasks, sprigs and branches; others yard wide in imitation of marble and other coloured wainscots, others in yard wide embossed work, and a curious sort of flock work in imitation of Cassaws and other hangings of curious figures and colours."

In France the first generation of flock papers died out before they were in general use, to be succeeded by the illuminated papers of the school of Papillon. In England, on the contrary, flock papers took root and flourished. The process was perfected

BY COURTESY OF JOHN LINE & SONS
AN EXPERT AT WORK ON THE PRODUCTION OF A HAND-MADE DESIGN

and improved in this country, and in 1750 England suddenly began to ship flock papers back to France. The greatest success was the brocaded paper done on blue or gold grounds, which quickly became the rage in Paris. Madame de Pompadour commanded it to be hung in her dressing room at Versailles and in her bathroom at the Château des Champs. Ladies of the court sent their Gobelin tapestries to storage, in order to put "English blue paper" in their place. The charming designs of Papillon were forgotten or depreciated in devotion to this new fashion.

An English paper-stainer named Lancake went so far as to get permission to establish a factory at Carrières, near Paris, for the production of flock papers, and French manufacturers were driven to defend themselves against the English invasion. They knew the secret process and had no difficulty in adapting themselves to the taste of the day. To prove their superiority they used chopped silk instead of chopped wool, imitating the finest silks that came from the looms of Lyons.

It is interesting to observe how these papers were applied to the wall. Early papers in England were nailed on with flat-headed nails. Later papers, both in France and England, were applied with paste—but flock papers were treated with as much courtesy as if they had been the actual stuffs of which they were imitations. They were mounted on a chassis, or stretcher, which was first nailed to the wall and covered with stout linen, tightly stretched. Over this brown paper was pasted as a lining paper; the flock paper was applied when this was dry.

Paper Imitating Painted Panels.—The second half of the 18th century was marked by a new development in paper hangings, due largely to the genius of Réveillon, a Paris manufacturer, who took his inspiration from painted room-decorations executed by the artists of the day. Réveillon determined to make paper panels of such a character that they might be used in wood-panelled rooms in place of decorations painted on canvas or on wood, and to employ the best artists as his designers. The panels created for him by Huet, Cietti, J. B. Fay, Prieur and Lavallée-Poussin, executed with Réveillon's amazing knowledge of technique, are undoubtedly the most beautiful wall-papers that have ever been made. (Several panels by Prieur will be found in the Musée des Arts Décoratifs in Paris.)

In Réveillon's opinion, no paper stock existed that was fine enough to be worthy of these designs. He reports in his *Mémoires* that he saw a piece of vellum paper brought to France by Benjamin Franklin—paper that was used in England by Baskerville in printing fine books—and that he greatly desired to reproduce it. In 1770 he purchased a paper-mill at Courtalin-en-Brie, and began there the fabrication of the paper for which in 1786 he was awarded the Prize for the Encouragement of Useful Arts.

His wall-paper factory in Paris employed about 300 workmen. It received from Louis XVI. in 1784 the title of "royal manufactory," which gave Réveillon among other privileges the right to add to his sign the crown and the three fleurs-de-lys. The establishment met disaster in the riot of April 28, 1789, at the beginning of the French Revolution. Incited by jealous competitors, and roused by the rumour that their wages were to be cut, his band of employees pillaged the factory, leaving destruction and ruin in their wake. Unable to find and murder Réveillon himself, they burned him in effigy. The guards, ordered out to quell the disturbance, fired on the mob. Many persons were killed and several were sent to prison.

Réveillon fled to refuge, and from his retreat sent a despairing letter to Necker; in reply he was offered by the king a sum of 30,000 francs to offset his loss and was assured of protection and continuance of royal favour if he would resume his work. Discouraged and broken in health and spirit, however, he emigrated to England where he died a few years later, leaving his factory in the hands of Jacquemart and Bénard, who proved to be worthy successors. Although chiefly noted for panel-decorations designed by eminent artists, Réveillon also made all the various sorts of papers that expressed the taste of his day; to these he gave a distinction of design and colouring that endowed them with a special sense of refinement and grace.

Similar developments in the printing of paper panels occurred

in England around 1754 under the direction of John Baptist Jackson, who is the most interesting and prominent character in the history of English wall-paper. Jackson published a book on the "Invention of Engraving and Printing in Chiaro oscuro . . . and the application of it to the Making of Paper Hangings of Taste, Duration and Elegance." The book is written largely about himself, styled "Author of that Paper Manufactory now carrying on at Battersea." It was here that Jackson produced the famous series of Venetian prints ordered by Horace Walpole for Strawberry Hill, and also the large landscape-panels and medallions which are a curious mixture of Pillement and Piranesi.

Jackson's papers were printed in oil on a rolling press of his own invention. He guaranteed that "the colour will never fly off—no water or damp can have the least effect on it." Engravings made by him in Rome and in Venice, copies of Canaletto, Rembrandt, Titian and other old masters, were used as subjects of these panels. He also reproduced statues like the Belvedere Apollo, the Dying Gladiator, and the Venus de' Medici, so that "the person who cannot purchase the statues themselves may have these prints in their places." The latter part of the 18th century in England was also notable for the work of Francis Frederick and George Eckhardt, who established a factory in Chelsea in 1786 and executed some remarkable papers with needlework designs, and others with printing in silver-leaf.

In 1712, under Queen Anne, a tax of one penny a square yard was assessed on English paper-hangings. In 1714 this tax was increased one-half. No change in duty was made thereafter for nearly a century. Wall-paper was exempted from duty in 1825, the same year in which prohibition of importation of this manufactured article was removed.

Paper in continuous rolls was invented by Nicholas Louis Robert, of Essônes in 1799, and the English patents, "to make paper without seam or join," were obtained in London in 1801 by John Gamble and Didot St. Leger. The use of paper of continuous lengths was not, however, permitted in England before 1830, because of the important revenue derived from the tax stamps on the small sheets. France, meanwhile, made use of the new invention after 1810.

Scenic Papers.—The attempts made by Réveillon and Jackson to produce paper which represented paintings in panels had a natural development in wall-paper history. They were followed by the epoch of scenic papers—panoramas that covered the entire room with a landscape or a story without repetition.

Late in the 18th century, after the papers of the Revolution with their liberty caps and tricolor cockades and fasces, their pyramids and palms, had come and gone, the makers of wall-paper took up this new idea and carried it out with infinite detail. Robert, whose partner, Arthur, died on the guillotine, produced a *Directoire* paper with designs of Bosio. Jacquemart and Bénard printed the "Hunt" at Compiègne, of which there is a set in the Metropolitan Museum of Art in New York and also in the Victoria and Albert Museum, London. But the two specially prominent names in the realm of scenic papers are those of Zuber and Dufour.

Zuber's factory, founded in 1790 and still in operation, is at Rixheim in Alsace. In 1804 this paper factory issued the "Vues de Suisse," which, although crude in colour and style, roused great interest because of their decorative possibilities. In 1825 appeared "Paysage des Lointains," and in 1830, "Paysage de Brezil," designed by Rugendas. In 1831 Zuber printed the *Paysage à Chasse*. "Scenic America" was first edited in 1834, designed by Zipelius and Ehrmann. With its colourful views of West Point, Niagara Falls, New York Bay, Boston Harbour, the Natural Bridge in Virginia, and the Dance of the Winnebago Indians, it has proved to be one of the most popular of all the scenic papers, and new editions are still being issued each year.

In 1838 came the "Courses des Chevaux" in grisaille, with chariot racing in Rome, obstacle racing in France and flat racing at Newmarket. In the same year, Zuber issued "The War of Independence," which was printed with the background of Scenic America, but with Continental soldiers, Washington's triumphal entry into Boston, and the surrender of Cornwallis at Yorktown in

place of the figures in the foreground. This paper, of which no editions were printed for more than 60 years, has recently been re-edited. "Isola Belle" was brought out by Zuber in 1843, and "Eldorado" appeared in 1848. Zuber was the only manufacturer in the provinces who rivalled the scenic papers produced by the Parisian makers, and is the only one, except Desfossé, whose papers are still published today, using the old blocks. The Zuber factory printed the first continuous rolls in colour in 1829, and obtained from Manchester in 1850 the first cylinder colour-press to come into France.

At the head of the distinguished Parisian group making fine scenic papers in the early 19th century, stood Joseph Dufour, who made his reputation with the Captain Cook wall-paper printed in Mâcon in 1804-1805 (anno XIII.). This picture-paper represented a number of scenes from Captain Cook's voyages in the islands of the Pacific ocean; it is very rich in colouring, and tapestry-like.

It was the usual custom to publish a descriptive booklet with each scenic paper, giving careful instructions for matching and putting the strips together, whenever a new design appeared. Many of these papers were sent to America, wrapped in tin-foil tubes to protect them against dampness. They were put on the walls with the aid of a numbered chart, after the fashion of children's picture-puzzles. Their success in France and America was not repeated in England, where they were little known.

In 1808, Dufour presented to his public twelve panels representing the Twelve Months of the Year, designed by Fragonard fils; and in 1814, a classic paper in grisaille, with all the gods and goddesses, known as the "Galerie Mythologique." But his masterpiece was the "Cupid and Psyche" paper, which appeared in 1816. The designs for this paper were made by Louis Lafitte, who exhibited them in the Salon in 1817. Two of Dufour's papers, especially popular in America, were "The Bay of Naples" and "The Monuments of Paris" (1815). They may still be found in many old New England houses. Other notable scenic papers from Dufour's ateliers were "Paul and Virginia" (1820, designed by Brock); "Olympic Fêtes" (1824, designed by Mader père); "The Voyages of Antenor"; "The French in Egypt" (1814); "Telemachus in the Island of Calypso" (1825); "The Banks of the Bosphorus" (1816); "Views of Hindustan," and "Views of Turkey." Other famous makers of scenic papers were Jourdan-Villars, who issued the "Battle of Austerlitz" in 1806; Delicourt, producer of "The Great Hunt" in 1851; and Cler and Margéridon, who edited the "Fêtes Louis XIII."

The operations of making scenic papers were common to all fabricants. Small sheets were first glued together to form a "roll," the paper was then sized, and spread out to its full length on long tables, where it received the background colour, put on by a workman with a brush in each hand. After the rolls had been hung up to dry, they were polished on the back. They were then ready for the printer and his wood-blocks. Tempera colours, mixed with hot glue, were used for printing, and a different block was used for each colour, which necessitated as many blocks as there were colours or shades in the design. One colour was printed at a time throughout each roll, and left to dry before proceeding with another. The printing of such papers in this fashion to-day is not a commercial possibility, because of lack of workmen sufficiently skilled in the art, the high cost of labour, and the length of time required to complete a set.

Scenic papers of a date later than the discovery of continuous paper were still printed on small sheets, the economical manufacturers having a supply of the old paper in stock, and finding that it was of better quality than machine-made paper. It may be noted that the 19th century scenic papers still in existence owe their long life to the durability of the material of which they were made. Panoramic decorations of wall-paper commenced to fall into disfavor about the middle of the century. The advent of the printing machine in 1849 discouraged any further attempts of this magnitude, and, since then, the old order of hand-printers has almost passed away.

Early American Wall-papers.—The first wall-papers used in America were naturally imported from England or from France.

They were sold by book-sellers and stationers in quires and reams, as they were sold abroad. For the convenience of housewives, they were also peddled about from door to door. "Painted paper" is found in the inventory of Michael Perry in Boston in 1700; Daniel Henschman of the same city records the sales of quires of painted paper between 1712 and 1714. "Stampt paper in rolls for to paper rooms" is first advertised by John Phillips in the *New England Journal* in 1730.

Plunket Fleeson of Philadelphia founded the first American manufactory in 1739, and sold his papers in the shop with his other wares, which included "bedticks, live geese feathers, blankets and sacking bottoms." In 1769 he advertised "American paper-hangings, made in Philadelphia, of all kinds and colors, not inferior to those generally imported, and as low in price." He suggested also that "every one among us who wishes prosperity to America will give preference to our own manufacture, especially on the above proposition, if equally good and cheap."

Wall-paper was not yet important enough to induce merchants to devote their whole time to it; so it was often sold by the upholsterers and undertakers, as well as by the ironmongers and those who furnished army equipment. James White, arriving from London in 1754, announced "paper-hangings, put up so as not to be affected by the hottest weather, also funerals furnished and shrouds, either pinked in London or plain and pleated, and sheets."

Between the years of 1740 and the outbreak of the Revolution, there were constant importations of paper-hangings, arriving from London and Paris by every ship. It is to be supposed that American manufacturers kept pace as best they could with foreign fashions. In Philadelphia, Ryves and Fletcher, Joseph Dickinson, Burrill and Edward Carnes, and William Poyntell were importers and manufacturers. In Boston, Jerathmeel Pierce, John Welsh, Jr., Moses Grant, Joseph Hovey, and Prentiss and May made paper-hangings "equal to any on the continent." In New York State were John Rugar and John Howell and Son. In Springfield, New Jersey, was the important firm of Mackay and Dixey. An event in the history of American wall-paper was the printing of the "Washington Memorial" paper in 1800 by Ebenezer Clough of Boston.

Brissot de Warville reported to France in 1795 that paper-hangings were "universal in the United States. No other decoration is known there; almost all houses are neat and decent." The rage for scenic papers possessed New England by 1817. Many of them were brought across the ocean as wedding gifts, or birthday or anniversary presents, in special charge of the sea-captains. Wall-paper establishments soon followed the new fashion, and imported many sets of these "varieties of views." In 1844 John Howell brought from England the first colour-printing machine, and wall-paper entered on a great era of development which continued until the close of the Victorian age.

Chinese Wall-papers.—With the founding of the Dutch East India Company in 1597, the English East India Company in 1600, and the French Company in 1660, Europe was inundated with a flood of Oriental stuffs, and *objets d'art*. In the ships with these goods came wall-papers that were different from anything the Occident had yet seen. They were painted by hand with birds and flowers, forming delightful backgrounds for the lacquer and Oriental porcelains that were fashionable. The first of these papers to arrive in the western world were presented by the great Hongs, or merchants, to their important customers to take home as gifts after the consummation of some important sale.

Such gifts were the objects of great admiration and curiosity, and many friends desired similar sets. Orders for them went back on the next ship and soon a regular commerce in Chinese papers was established. Shipments were made with the tea-boxes; Mincing lane in London became the centre for their distribution. To avoid the long delay caused by ordering paper specially painted in China, attempts were made to imitate them, both in France and in England, thus creating what are known as Anglo-Chinese and Franco-Chinese wall-papers. As such designs were looked on favourably by Badminton and Versailles, both the original Chinese papers and their imitations were stamped with royal approval.

ENGLISH AND FRENCH WALL-PAPERS, 16TH-19TH CENTURY

1. English wall-paper, 16th century; Elizabethan era (1558-1603). Wood-block print in black and white. 2. English wall-paper, 18th century, with Chinese design of birds and foliage, a favourite motif up to 1750. 3. Domino wall-paper, France, late 18th century. This example (1795-1800) clearly shows the *Directoire* style in the medallions containing furniture and pottery. The colours are red-brown, green-grey and tan. Domino papers were printed with designs in compartments, geometrical figures, or grotesques. 4. French wall-paper, early 19th century. In sepia, black and white. These scenic papers were very popular in France and America. 5. Overdoor wall-paper by J. B. Reveillon, France, 2d half of 18th century. Reveillon manufactured paper panels designed by artists;

this one was in the room with the Cietti paper shown in fig. 6. 6. Wall-paper designed by Cietti, Italy, and printed by J. B. Reveillon between 1780 and 1789. Cietti here uses a Pompeian design and colours, precursors of the less delicate Pompeian styles popular during the Directory (1795-99). 7. French wall-paper, 18th century panel designed by Prieur, manufactured by J. B. Reveillon; now in the Musée des Arts Decoratifs, Paris. 8. "Renaud and Armide," printed by Leroy, France, 1828. Here Renaud, the Crusader, is shown with the enchantress, Armide, in her pleasure-gardens. (See Plate II., fig. 7.) 9 and 10. Classic wall-paper, "La Galerie Mythologique" (1814), by Joseph Dufour, Paris. This paper, in *grisaille* and green, represented all the gods and goddesses

WALL-PAPERS, 18TH AND 19TH CENTURIES

1. "The Banks of the Bosphorus" ("Les Rives du Bosphore") paper, printed by Joseph Dufour, Paris, 1816. The complete set, consisting of 26 strips in colour, represents landscapes with river and *caïques*
2. Hall of Hamilton House, South Berwick, Maine; paper with repeated arches
3. "Views of Hindustan" ("Paysage Indien") paper, printed by Joseph Dufour, Paris, 1815. The set consists of 20 strips in colour. A set still exists in the Putnam-Hanson house, 94 Boston St., Salem, Mass.
4. Blue wall-paper, one of three panels, from designs by Boilly (1761-1845), France
5. "Paul and Virginia" paper, illustrating the story by Bernardin de Saint-

- Pierre, designed by Brock (1820), printed by Joseph Dufour, Paris
6. Old Canton wall-paper, 18th century, showing *The Making of Porcelain*, now at Beauport, Gloucester, Mass. This fine Chinese paper, treating also the subjects *The Cultivation of Tea* and *The Raising of Rice*, was imported to America shortly after 1770, by Robert Morris. The complete set consists of 40 strips, each 12 ft. x 4 ft. To-day half of the paper is in Mr. Henry D. Sleeper's house, Gloucester, the remainder at Providence, R.I. (see fig. 8)
7. Mrs. Henry Rea's hall, with painted paper panels, formerly belonging to George Sand
8. Old Canton wall-paper, 18th century, now in the ball-room of Mrs. E. Bruce Merriman, Providence, R.I. (see fig. 6)

Interesting examples of some Anglo-Chinese designs exist in the Victoria and Albert Museum, London. The average height of Chinese papers was 12 feet. The favourite designs up to the middle of the 18th century were birds and flowers; after 1750 these were largely superseded by landscapes with figures.

Occasionally Anglo-Chinese papers were ordered for American homes, as for example the one executed in London for Thomas Hancock in 1793 in accordance with his command to make "a great variety of different Sorts of Birds, Peacocks, Macoys, Squirrel, Monkys, Fruit and Flowers."

The English Gothic Revival.—Notable in the last half of the 19th century in England was the Gothic revival in paper-hangings. In 1843 Augustus Welby Pugin made for the new Parliament Buildings the papers in Gothic patterns that are an admirable expression of the spirit of the architecture. The Daisy pattern of William Morris, the first of a long series, including the Trellis, the Pomegranate and the Acanthus, was published in 1862. All of these papers were an attempt in colour and pattern to revive something from the old Gothic tapestries. They gave inspiration in their turn to Owen Jones and later Gothicists. Since then, no great achievements are to be noted in the history of English paper-hangings.

Wall-paper in Modern Decoration.—The reaction against the over-decorated Victorian era, and the lack of good designs in machine-made wall-papers resulted after 1900 in a temporary disuse of this practical wall-decoration, which had filled a need for three centuries. In its place for twenty years or so have been monotonous putty-coloured walls, panelled with picture mouldings.

Wall-paper, however, has recently come back into its own. A definite attempt to revive the old designs of the 18th century and the old processes of printing has resulted in great benefit to this humble art. With this revival of old designs, much study has been made of the fashions of hanging wall-papers a century ago. In many early houses only three walls of a room were covered with design; the fourth, usually the fireplace wall, was panelled with wood. This idea is being repeated in many country houses to-day.

Modern lovers of wall-paper have also discovered that a partially-papered wall is sometimes more successful than a wholly-papered wall. Hence the use of wall-paper in panels, outlined either with wood mouldings or with paper borders such as were used in olden times to complete a room. These panels are carefully designed to fit the architecture of the room, and the painting of intervening wall-spaces and door and window-trims is carefully studied to complement the colours of the paper.

An enthusiastic revival of the use of scenic papers may also be noted, which has resulted in the pillaging of many houses that contain original examples of Dufour's and Zuber's work. Such papers as the "Bay of Naples," the "Monuments of Paris," and "Captain Cook" are eagerly sought for use in entrance halls and dining-rooms, where there are few high pieces of furniture to hide the panorama. To protect these papers, and assure the possibility of their safe removal, it is customary to line the walls with canvas before the paper is applied. Canvas and paper may be removed with great facility. The decorated bathroom is a new development of the day, and here again wall-paper has lent its aid. Gay designs, given a coat of waterproof varnish, make bathrooms into places of colour and beauty, and provide a durable decoration.

In rooms where plain walls are a requirement, a wall-paper cornice is sometimes used, with a border above the chair-rail, in a fashion that recalls the old stencilled rooms of early days, where each member of the family took part in stencilling a frieze. Paper panels are again being set into wood rooms, as Reveillon desired, making a pleasant contrast between the panel-decorations and the natural colour of the wood.

Modern manufacturers are producing many good "background papers" for those who have pictures to hang on their walls, and also many papers that are an adequate decoration in themselves. There are glazed papers for the kitchen, marbled papers for the hall, and an imitation of wood-graining that gives the effect of pine.

Papers that represent stuffs, such as toile de Jouy, chintzes and damasks; papers that represent paintings; and papers that are good imitations of the Chinese are relied on to give decorative effects and variety in modern homes.

Present-day schemes of modernist decoration include, beside the textures of wood and glass and metal, many gold and silver wall-papers, and others done in brilliant colours and daring designs. These are used by the modernists in a curious fashion, four or five different papers being combined in the same room—a frieze of one color and pattern at the ceiling line, another paper on the dado, and two or more different papers with their borders on the field of the wall. Many examples of this type of room were seen in the 1926 Paris exhibition of *Arts decoratifs*.

Wall-paper has also been found useful for enlivening the small decorative objects of the household. Wall-paper screens give a note of colour and interest to a room, and have become practical since the discovery of a method of making them puncture-proof. Wall-paper desk-boxes, blotters, and scrap-baskets, with a coat of shellac, are quite as decorative as leather. Wall-paper lampshades in bedrooms and country houses are amusing and gay. Wall-paper shelf-borders decorate a closet at small expense, while bandboxes and dress-boxes of wall-paper on the shelves make uniform and colourful dust-protectors.

WOOD FINISHES, PAINTS AND VARNISHES

Wood, which is both the most available and the most easily workable of structural materials in the majority of the habitable regions of the globe, has from the earliest times been extensively utilized. When, in the course of cultural development, the sense for beauty was awakened, the art of wood finishing had its beginning. In ancient Egypt the embellishment of wood structures by painting and gilding reached a comparatively high state of development, and it was diffused thence, slowly, eastward and westward throughout the settled regions of the world. Each country receiving the tradition, modified and adapted it in conformity with the nature of the native woods, the materials available and the cultural genius of its people.

In the Far East, and especially in China, a highly specialized art developed under the early dynasties, and was carried thence to Japan where it reached its highest state of development. The treatment familiar on Chinese and Japanese articles of vertu and known as lacquer is based on the sap of a tree extensively cultivated in both countries solely for this use, the *Rhus verniciifera*, which is closely related to the *Rhus toxicodendron* of the West, and similarly poisonous. Various grades of lacquer or varnish are made by treatment and selection of its sap or juice, and the lacquer, coloured with selected dyes or pigments is applied in successive coats (in the finer pieces as many as 16) each laboriously ground down with emery flour or other abrasives and as laboriously polished with different substances, the final polish being given with pulverized deer's horn. Each coat must be dried in the dark and in a moist atmosphere. Inlay work and other decorative materials are applied to the lacquer while it is still moist and imbedded therein by the application of subsequent coats.

In Europe during the middle ages and later, besides gilding and similar processes, the decoration of wood consisted principally in staining with a vegetable dye, such as a decoction of log wood, or a chemical agent, such as tannic acid, and the subsequent application of a drying oil or a spirit varnish, consisting of a gum resin (*sandarach elemi*, *damar*, etc.) dissolved in a volatile solvent, or East Indian lac dissolved in alcohol. Wax was also a favourite material for finishing such work.

The French artisans early developed a finishing process of unique quality which is still popular under the name "French Polish." The process is simple though somewhat tedious. After

the surface has been properly prepared a very dilute solution of shellac in alcohol is applied with a pad made of stocking material. As soon as this coat is dry another is applied over it. This is repeated until the required lustre is obtained. Then, using the same pad, the surface is polished with a very little linseed oil, and after standing over night the polishing with oil is repeated. The soft sheen obtained in this way cannot be duplicated.

The varieties of woods used in construction at the present time differ widely in physical characteristics as well as in their chemical reactions. As a consequence different methods of initial treatment or preparation are required. Wood finishers classify them as "soft" or "hard," connoting generally their relative absorbent properties; "open" or "close" grain, indicating the relative solidity of the surface offered for finishing; resinous or non-resinous, the former class including woods such as cypress, which contain juices that are not really resins; and "plain" or "figured," these terms connoting the visual prominence of the wood structure.

All open grain woods require "filling" as a preliminary to the decorative treatment. This so-called grain consists of the sap-ducts which have been laid open in cutting the lumber, and becomes apparent in those woods having large sap-ducts. These are chiefly the woods classified also as "hard woods." The principal types encountered are butternut, walnut and the *juglans* family in general; oak, of all varieties; ash, elm, mahogany, rosewood, and chestnut. The following, classified as close grain woods, are, with the exception of maple, birch, cherry, gum and yellow pine, also classified as soft: bass, beech, birch, cedar, cherry, cotton wood, cypress, fir, gum, hemlock, holly, maple, the pines, poplar, redwood, spruce, sycamore and tulip. The preliminary treatment in all cases includes stopping of cracks and nail holes with putty coloured to match the finish to be applied, sandpapering with fine sandpaper to a smooth surface, removal of blemishes if the finish is to be transparent, and thorough dusting off.

Transparent Finish in the Natural Colour.—The woods suited to this treatment are those possessed of natural beauty due to their colour or configuration of grain. Those ordinarily selected for this treatment are the hard woods in general, sometimes including close grained woods like the hard pines, the maples, some of the cedars, cherry, cypress and some types of birch. The natural beauty of certain of these woods, especially oak, is often enhanced by "quarter sawing" in which the boards are cut diagonally across the log.

The more open grain woods are "filled" with paste wood-filler, of which the best grades consist of finely powdered quartz ground to a rather stiff paste in a special varnish. The filler may be coloured or uncoloured. In the latter case, being transparent, it merely provides a smooth surface for varnishing. In the former, the grain is more clearly defined and very beautiful effects may be obtained by the addition of colour, aluminium bronze or white pigment. The paste filler is applied across the grain with a stiff brush, and after it has "set," but before it becomes hard, the surplus is wiped off, again across the grain, with excelsior, burlap or similar material. After the remaining filler has become completely hard, the entire surface is sandpapered with fine sandpaper and carefully dusted off. The first coat of varnish is then applied, using a flat varnish brush. The grade of varnish used depends upon the finish desired. If the work is to be rubbed or polished, the varnish selected is a rubbing and polishing grade; if not, a softer and more elastic grade of interior varnish is usually preferred. In either case three or more successive coats are applied if a good finish is desired. Sufficient time is allowed for the complete drying of each coat—from 24 to 48 hours, depending upon the character of the varnish. However, quick drying varnishes made from synthetic resins, in which the drying time has been reduced to a few hours, have recently been introduced.

If the more beautiful finish produced by rubbing is desired, each coat of varnish after thorough drying, is rubbed with powdered pumice stone and water or pumice stone and oil to produce a perfectly smooth surface. If a dull or low lustre finish is desired, the final coat is rubbed only. If a lustrous finish is required the rubbing of the final coat is followed by polishing with rottenstone and oil. For both rubbing and polishing a pad made by

fastening felt to a flat block is most serviceable, and for sandpapering a similar pad is serviceable, the sandpaper being laid over the felt.

Staining.—The modern tendency in wood finishing is to colour the wood before applying the finish. In fact, it has long been the practice to stain many of the choicer woods, such as mahogany, walnut, rosewood, oak, etc. The natural colour of mahogany is a very pale yellow, but staining of this wood has been so long in vogue that the very name suggests red, though in recent years brown has become the more popular colour. Certain woods are also stained to imitate rarer varieties, as, for instance, birch and maple to simulate mahogany, or birch in imitation of cherry.

The older craftsmen employed a variety of vegetable dyes and various chemicals to produce the effects they required, but with the invention of coal-tar dyes, in their great variety and beauty, the older art has largely fallen into disuse. Many of these so-called "aniline dyes" are now sold as powders under the names of the woods on which they are supposed to be used, as, for example, mahogany brown, mahogany red, walnut brown, oak stain, etc. Most of the stains used in ordinary finishing, however, are purchased ready for use from the manufacturers, who furnish them in endless variety.

Stains are of five types, selected according to the woods on which they are to be used—water stains, oil stains, spirit stains, acid stains, and penetrating stains, the last including alkaline stains. The water stains are usually prepared by the user by dissolving the dye in water, though they can be purchased in solution; the rest are obtained ready for use from the manufacturer. The oil stains are generally preferable to the water stains, since they do not "raise the grain" of the wood like the latter, which necessitate sand-papering. The water stains nevertheless are preferred for the light coloured soft, absorbent woods, because oil has a tendency to darken these. Where lacquer is the finishing material, water stains are usually preferred, because of the better adhesion of the finish after their use. Many stains are also made with the same insoluble pigments that are used in the manufacture of paint; and finally, varnish stains are procurable for first coating in which the stain and the first coat of varnish are applied in one operation. Acetic acid is usually added to some stains to increase the solubility of the dyes not readily soluble in water; and oil or spirit—usually turpentine or an alcohol—is substituted for water in other stains for similar reasons.

With water or spirit stain the procedure is to apply the stain with a soft brush. Skill is required here to obtain evenness of distribution. A coat of dilute shellac varnish is then applied. This serves to stiffen the wood fibres that have been "raised" by the stain, so that they may be easily cut. The surface is then lightly sand-papered with fine sand-paper. The transparent wood-filler is next applied if required, followed by a second application of stain, if required, and a second light sand-papering. The varnishing follows—two, three, or more coats, either rubbed or un-rubbed, according to the finish desired.

The term enamel, originally applied to fused vitreous coatings on metals, is now also used for opaque pigmented varnish coatings. Such finishes were formerly produced with spirit varnishes (principally dammar) but are now commonly produced with prepared enamels. As found in the market, the better grades of these consist of zinc oxide or the best quality of lithopone ground in a special rubbing varnish.

In producing the finish the wood is first filled, if necessary. One or two coats of flat drying oil paint are then applied, followed by two or more coats of the enamel, according to the quality of finish desired. These coats may be rubbed, as in clear varnish finishing, and the final coat polished; or they may be applied successively without further treatment.

Graining.—This type of finish, once universal, is now rarely used, except where necessary to match old work. Its purpose is to imitate with cheaper woods the colour and figuration of more expensive woods. Expert grainers of the old school can so closely simulate rare and costly woods that it is almost impossible for the eye alone to distinguish between them. Woods usually selected for the purpose are the common soft close grained woods, such as

pine, poplar, soft maple, etc. A "ground colour" closely resembling the prevailing colour of the wood to be imitated is first applied, two or more coats being necessary. These colours may be bought ready for use. Specially prepared graining colours to match the deeper shades of the wood to be imitated are then applied evenly with a soft flat brush. This process is called "rubbing in," from the fact that paste colours formerly used, necessitated rubbing to spread them. A comb of steel or hard rubber is then passed over the portions of the work that are to be left plain. For imitating the less open grain hard woods, such as walnut, cypress, yellow pine, cherry, etc., the steel comb is covered with a rag. Rags are also used for wiping out "heart-grains." Then by the use of combs and wiping rags the expert grainer can closely imitate the grain pattern of any wood. The finishing touch is added by "overgraining," to soften and blend the work, with water colour, to which a little beer or vinegar has been added. For commercial work machines, stencils and transfers are available which fairly imitate the grains of various woods. The chief objection to them is that the pattern is monotonously duplicated. The most successful of these is perhaps the "graining wheel," consisting essentially of a printer's ink roller bearing the grain pattern in relief. A more recent invention consists of a steel roller which stamps the grain pattern into the substance of the wood, which is then filled, stained and treated exactly like the wood imitated. The completed work is preserved by varnishing.

WAX FINISH AND PAINTING

Instead of varnish, wax is often used for finishing natural or stained wood surfaces. This is one of the oldest methods of wood finishing. The material used was formerly beeswax dissolved, with the aid of heat, in turpentine, or simply the plain powdered wax, spread with the aid of weighted brushes. Both methods are still used, especially in the finishing of hardwood floors, but the commoner modern practice is to use prepared waxes, consisting of several kinds of wax with a small proportion of a volatile solvent. This treatment produces a dull finish, which becomes lustrous with rubbing. The usual undercoat for wax is shellac varnish. No special skill is required to produce this finish, vigorous rubbing being the chief essential. The same effect is produced in more permanent form by the so-called "hard wax finishes," containing carnauba or other hard waxes.

While not usually classified as a method of wood-finishing, painting is more commonly practised than any other method. In the methods just considered the purpose is to enhance the natural beauty of the wood itself, whereas paint is applied for the purpose of concealing the wood. Other types of finishing require that the wood shall be uniform in colour and free from defects and blemishes, but as paint (like enamel, already considered) permanently hides the surface, no selection is necessary.

Preparation for painting is essentially the same as for the types of finishing already discussed. The surface is sandpapered; open grain woods are filled with paste filler coloured with the paint to be used; nail holes, cracks, etc., are stopped with putty similarly coloured; the surface is again sandpapered; and finally all resinous spots and knots are coated with a shellac varnish. The first or "priming" coat is then applied. This coat usually contains somewhat more oil and more volatile "thinner" (turpentine or mineral spirit) than the succeeding coats, to facilitate penetration and assure firm adhesion. The second coat contains less oil and less volatile "thinner" than the priming coat; and the third, which is usually the finishing coat, less "thinner" than the second coat.

The methods of decoration with paint are of infinite variety, depending upon the taste, skill and ingenuity of the craftsman, since the hues, tints and shades at his disposal are practically unlimited and the possible combinations countless.

Lacquer and Other Special Finishes.—The oriental lacquer produced from the *Rhus vernicifera* has already been described. Another type of finish, long used in the West for preserving the lustre of polished metal surfaces and called by the same name, consists simply of spirit varnish—resins dissolved in alcohol or other volatile solvent. This type was largely superseded for the purpose by another form of "lacquer" consisting of nitrated cellu-

lose dissolved in amyl acetate or other volatile solvent with the addition of various "plasticizers," such as castor oil. These were similar in general composition to collodion (nitro-cellulose dissolved in sulphuric ether) or celluloid, in which the plasticizer is camphor. The technical study of nitro-cellulose, stimulated by its importance in explosives, photography, moving pictures, the manufacture of artificial silk and of celluloid products, naturally led to a consideration of its possibilities as a decorative and protective coating. Research and experiment quickly led to the production of a nitro-cellulose, or "pyroxylin," which contained less nitrogen and was therefore more stable than the earlier types, and at the present time many industrial products requiring a finish are coated with pyroxylin lacquer.

Various chemicals which in reacting with the chemical components of the various woods produce colour changes of greater or less intensity are occasionally used by wood finishers, though to a less extent than formerly. The most popular of these is the treatment known as "fuming." It consisted formerly of prolonged exposure of the wood—chiefly oak or mahogany—to the fumes evolved from strong ammonia. It is now commonly brushed on the surface, but the older process yields more uniform effects. Other chemical stains with which varied effects may be produced on different woods are tannic, pyrogallol, chromic, picric, acetic, nitric, hydrochloric and sulphuric acids, the alkalis, potassium bichromate, potassium permanganate, copper sulphate (blue vitriol), ferrous sulphate (green vitriol), ferric chloride, chrome alum and manganese sulphate. These chemical agents all have the advantage of producing permanent coloration, in contradistinction to many of the commonly used dyes. Wood treated in this way is finished as with ordinary stains.

Various effects are produced by first applying ground coats of flat paint or enamel, and after this foundation is dry applying a coat of transparent glaze of a different colour and while still wet stippling, wiping with a rag in various patterns, imitating graining with brushes and a whisk broom, etc. The effect known as "antiquing" is produced in a similar manner, by applying over the flat ground coats a semi-transparent glaze coat of somewhat darker tone. Raw umber or a mixture of raw and burnt umber is commonly used. While the glaze is still wet it is wiped off with a soft rag. Sufficient colour remains to give the "antique" effect desired. The "old ivory" effect is produced by adding to white paint a little raw sienna and burnt umber for the ground coats and after these are dry glazing with a thin mixture of the raw sienna and burnt umber. Ebony is simulated by painting first with vermilion (Japan colour) and finishing with two or three coats of black tinted with Chinese blue. All these special finishes should be protected with one or two coats of varnish.

Spray Machine Finishing.—The spray painting machine was used to an unimportant extent from 1870 to 1923, but it was only with the introduction of pyroxylin lacquer into the furniture and automobile finishing field, in 1923, that it found extensive application. Since that date the improvement of the device has progressed rapidly and its adaptation to other fields has steadily spread. But for this machine the industrial lacquers, which dry too rapidly for application by brushing, could not have been utilized. With slight modifications it was found equally serviceable for the application of paint and varnish, and its use with these has rapidly expanded. With it many decorative effects, such as mottling, spatter finishes in one or several colours, glazing, colour misting, etc., can be produced rapidly and at comparatively slight expense. Modern pyroxylin lacquers are of three types: (1) clear, quick-drying, unpigmented lacquers, applied by the spray-gun; (2) quick-drying pigmented lacquers also applied by the spray-gun; (3) slower drying pigmented lacquers applied with a brush.

The first type, used to replace varnish in the finishing of furniture and similar industrial products, is applied to surfaces already stained, filled and otherwise prepared in practically the same way as for finishing with varnish. The lacquer coating hardens within a few minutes. Two or three coats are usually applied, the final coat being rubbed as in finishing with varnish. Pigmented spraying lacquers are most largely used for finishing automobiles, railway coaches and similar products. The rate of drying is somewhat

slower than that of the clear lacquer, but still quite rapid. Two or more coats are applied, with or without rubbing according to the finish desired.

Brushing lacquers were devised for domestic use. They are pigmented, like the coloured spraying lacquers, but the speed of drying has been retarded so as to permit application with a brush. They are, nevertheless, completely hard within about 30 minutes. They are "flowed" from the brush and cannot be worked over like varnish. The technique is different, but easy to acquire, and the results are novel and both beautiful and enduring.

Still more recently, to meet the competition of lacquer and to overcome some of its disadvantages, the quick-drying oil varnishes known as "four hour varnishes" have been developed. They are, to all intents and purposes, oil varnishes in which certain synthetic resins have been substituted for the fossil resins commonly employed.

INTERLACED ARCHES. Arches which span twice the width of the space between the piers of an arcade, so that each arch crosses two others. In some cases the arches interlace, their mouldings crossing alternately over and under those of the other arches; in some cases the whole is on one plane and the arches merely intersect. Interlacing arches are common in Romanesque work (see BYZANTINE AND ROMANESQUE ARCHITECTURE), especially Norman, and also in English Gothic (see Gothic Architecture), and are also occasionally used in Moorish work, as in the great mosque at Córdoba (8th century). For illustrations see ARCADE.

INTERLAKEN, a Swiss town (1,864 ft.) in the canton of Berne, situated on the flat plain (*Bödeli*) between the lakes of Brienz (E.) and of Thun (W.), and connected by steamer, as well as by railway (17½ m.) with the town of Thun. It is built on the left bank of the Aar, and grew up around the religious house of Austin Canons, founded about 1130 and suppressed in 1528. In the surviving buildings of the convent religious services (Anglican, Scottish Presbyterian and French Protestant) are now held, while the more modern castle is occupied by offices of the Cantonal Government. The fine and well-shaded avenue called the *Höhweg* runs through the main portion of the town, and is lined on the north side by a succession of huge hotels and the large Kursaal. Interlaken is much frequented in summer, partly because of the glorious view of the Jungfrau (13,669 ft.) which it commands to the south, and partly because it is the best starting-point for many excursions, as to Schynige Platte, Lauterbrunnen, Grindelwald, Mürren and Jungfrauoch. The lines serving these places all start from the eastern railway station (that from Thun reaches the western or main railway station), whence steamers depart for the Giessbach Falls, Brienz and Meiringen, on the way to Lucerne or to the Grimsel Pass. In 1920 the population of Interlaken was 3,261 (mainly Protestant and German-speaking). Opposite Interlaken, and on the right bank of the Aar is Unterseen (in 1900, 2,607 inhabitants), which was built in 1280 by Berthold von Eschenbach.

See *Fontes rerum Bernensium* (original documents up to 1366) (8 vols., Berne, 1883-1903); *Die Regesten des Klosters zu Interlaken* (Coire, 1849); E. Tatarinoff, *Die Entwicklung der Probstei Interlaken im XIII. Jahrhundert* (Schaffhausen, 1892).

INTERLOPER, one who interferes in affairs in which he has no concern. This word, with the verbal form "to interlope," first appears at the end of the 16th and beginning of the 17th century in connection with the interference of unauthorized persons in the trade monopoly of the Russia Company and later of the East India Company. The *New English Dictionary* quotes from H. Lane (1590), *Haklyt's Voyages*, "From those parts the Muscovites were furnished out of Dutchland by enterlopers with all arts

and artificers and had few or none by us," and also from the *Minutes of the Court of the East India Company*, 22nd of February 1615, "to examine all suspected persones that intend interloping into the East Indies or Muscovy." Edward Philips (*New World of Words*, 1658) defines interlopers at common law as those "that without legal authority intercept the trade of a company, as it were Interleapers." The word appears to be of English origin, for the Dutch *enterlooper*, smuggler, often given as the source, was taken from English, as was the French *interlope*. The word is a compound of *inter*, between, and *lope*, a dialectal variant of "leap." A common word for a vagrant, or "straggler," as it is defined, was till 1580 "landloper," and the combination of "straggler" and "interloper" is found in *Horsely's Travels* (Hakluyt Soc.), 1603-1627, "all interlopers and straglyng Englishmene lyving in that country."

INTERMEZZO. An interlude or entr'acte of a light and pleasing character serving as a contrast between the acts of a more serious drama or tragedy, and, in its developed form, continuing as an independent piece in this manner throughout the whole work, two entirely independent works, one serious and one light, being thus presented in alternate instalments. Pergolesi's famous *La serva Padrona* was such an intermezzo as originally produced. Nowadays the term is more generally applied to a short piece introduced between the larger movements of a symphony or sonata or to an independent short composition.

INTERNAL COMBUSTION ENGINES. An internal combustion engine is one in which energy is directly translated into mechanical power by causing an explosion to take place behind a piston. Professor Andrade has epigrammatically described this as "putting the furnace into the cylinder."

An explosion is an event of so sudden and violent a character that it might well seem impossible for man effectively to bring under his complete control so destructive and apparently unruly an agent; yet many billions of perfectly regulated gaseous explosions now minister daily to our needs in internal combustion engines of all kinds throughout the world.

Genghis Khan, in China, is recorded as having first used gunpowder in cannon about A.D. 1234 and King Edward III. in western Europe about A.D. 1327; the earliest proposal to utilize explosions (of gunpowder) to obtain *continuous* motive power was probably made by Christian Huygens in 1680, and Papin and the Abbé Hautefeuille later endeavoured to develop his proposal, but without success; it has now long been agreed that gunpowder is an entirely unsuitable substance for employment in any internal combustion engine.

R. Street, in 1794, proposed an engine driven by a flame-ignited explosive mixture of vapourised spirits of turpentine and air, and Sir Dugald Clerk regards this as the first real gas engine described in Britain. In 1820 W. Cecil at Cambridge described to the Cambridge Philosophical Society his engine operated by the explosions of a hydrogen-air mixture used to create a partial vacuum below a piston, the atmospheric pressure then producing the working stroke, much as in the earliest steam engines; he describes such an engine and states that at 60 revolutions per minute the explosions were perfectly regular; this is considered to have been the first actually working gas engine in the world.

With this brief introduction, we pass to the consideration of the various forms in which the internal combustion engine is used. These may be divided as follows:

- I. Gas Engines
- II. Heavy Oil Engines
- III. Light Oil (or Petrol) Engines
- IV. Special Engines

Separate articles are devoted to DIESEL ENGINE and AERO-ENGINE.

GAS ENGINES

The commercial career of the gas engine began with Samuel Brown (1823 onwards), whose design operated on the atmospheric-vacuum principle; actual Brown "gas-vacuum" engines were made and sold, and in 1832 were in regular service at Croydon, Soham, and Old Brompton; Brown engines were also fitted in a road

vehicle in 1826, and in a 36-foot boat in 1827.

Progress after this became more rapid; Wright in 1833 described an engine working with an inflammable mixture of gas and air much as in a normal double-acting high-pressure steam engine; followed William Barnett (1838) to whom the gas engine owes important advances, as he first realized the importance of compressing the explosive charge before ignition; he invented also the well known Barnett igniting cock which remained in general use up to as late as 1892. The next noteworthy advance was due to Barsanti and Matteucci who in 1859 produced a singular design known as the "free-piston" engine, subsequently improved in practical details by Otto & Langen; these inventors, at the 1867 Paris exhibition, first showed an actual example of their later well-known and widely used "free-piston" engine. In this the cylinder was vertical, of considerable height, and open at the top; it contained a heavy piston, below which, when in its lowest position, the explosive charge of gas and air was fired electrically; the piston was quite free in its ascent, and was fired upwards by the explosion, like a projectile; its ascent continued until the pressure below fell sufficiently for the atmospheric pressure and its friction, to bring it momentarily to rest; immediately thereafter the atmospheric pressure, its weight and the partial vacuum beneath it caused its rapid descent, during which a rack attached to the piston engaged with, and drove, a pinion, thus turning a shaft carrying a heavy fly-wheel; near the end of its descent the burnt gases were allowed to escape into the atmosphere. The engine was excessively noisy in operation and mechanically an outrage, but it possessed three advantages:

- (1) The exploded mixture was very rapidly expanded.
- (2) The expansion ratio obtained was considerable—often as much as 6:1.
- (3) The partial vacuum produced below the piston was utilized in its operation.

Hence, for the period, its gas consumption was quite economical, amounting to only about 44 cu.ft. per B.H.P. hour; to this comparative economy much of its commercial success was due.

Lenoir, in 1860, had commenced building his gas engines which were worked exactly like, and closely resembled in appearance, a double-acting steam engine of normal horizontal pattern; he introduced an uncompresssed mixture of gas and air into his cylinder during the first part of the stroke; cut off and ignition then simultaneously took place, and the remaining (*i.e.*, the working) portion of the stroke was then performed by the pressure and expansion of the exploded charge. A great many Lenoir engines were built, and worked with great regularity, smoothness and quietness; but they were very wasteful, the gas consumption being commonly roundly 100 cu.ft. per B.H.P. hour; mainly on this account the Lenoir engine was in due course entirely superseded by the mechanically much inferior Otto and Langen "free piston" engine above described.

By 1860 the necessity of pre-compressing the working charge before ignition was clearly recognised by several investigators; as early as 1799 Lebon, in France, had referred to compression, but the real originator of the practice was Barnett; in 1861 G. Schmidt stated definitely to the Society of German Engineers that explosion engines would work more economically, if the mixture were compressed to three atmospheres before ignition as in this way "a great expansion and heat transformation is possible."

The Beau de Rochas Cycle.—But it was in 1862 that the essential requirements, and the means of satisfying them, were first explicitly stated by Beau de Rochas in Paris, who then laid down the following four essential conditions for the greatest economy in working: (1) A maximum cylinder volume with a minimum cooling surface. (2) A maximum rapidity of expansion (3) A maximum ratio of expansion. (4) A maximum initial pressure of the ignited charge.

And he stated further that these conditions can be practically realized by the adoption of the following sequence of operations: (1) Suction during the first out-stroke of the piston. (2) Compression of the mixture during the following instroke. (3) Ignition of the compressed charge at the dead point, and subsequent expansion of the exploded gases during the next out-stroke; this is

the "working stroke." (4) Expulsion of the burnt and expanded gases during the next in-stroke.

This is the celebrated Beau de Rochas cycle now universally employed in all "four-stroke" cycle internal combustion engines.

The Otto Gas Engine.—Another 14 years elapsed, however, before de Rochas' suggestions were embodied in an actual engine; but in 1876 Otto produced the world-famous "Otto silent gas engine," in which the "de Rochas" or "four-stroke" or "Otto" cycle, as it is variously termed, was strictly followed; and the Otto silent gas engine at last launched the internal combustion engine upon its amazing commercial career.

A single-acting four-stroke internal combustion engine of the simplest possible type is shown diagrammatically in fig. 1. A cylinder, open at one end, is fitted with a closely fitting piston which drives a crankshaft through the medium of the connecting rod indicated; when the piston is in its uppermost position there is still a portion of the cylinder volume above it, and this is termed the "combustion chamber"; forming part of this chamber is the valve-pocket containing an inlet valve A (here shown as of the simplest "automatic" type—as used in early engines), and an exhaust valve B which is operated by means of a cam C and "tappet-rod" D. The cam C is borne on a shaft gear-driven at half-speed from the

FIG. 1.—DIAGRAM SHOWING VALVE AND CAM OPERATIONS OF 4-STROKE CYCLE INTERNAL COMBUSTION ENGINE

crankshaft as indicated by the dotted circles; this is termed the "cam-shaft" or "half-time shaft" or "timing shaft." The action is as follows:—Suppose that by some means the engine has been set in motion. On the first down-stroke of the piston the partial vacuum produced above it causes the automatic inlet valve A to open, and a mixture of gas and air to rush in, filling the combustion chamber and volume swept out by the piston; this is the *suction stroke*. On the succeeding up-stroke the automatic inlet valve at once closes, and the charge of gas and air is compressed by the ascending piston into the combustion chamber; this is the *compression stroke*. At the upper dead point the compressed charge is

ignited by some suitable means, explosion instantly takes place, a great rise of pressure occurs, and the piston is driven forcibly downwards by the inflamed mixture whose pressure and temperature rapidly fall during the expansion; this is the *working stroke*. At the end of this stroke the exhaust valve B is lifted by its cam and held open throughout the succeeding up-stroke, causing the expanded and burned gases to be discharged into the atmosphere;

FROM GIBSON AND CHORLTON, "MODERN MECHANICAL ENGINEERING" (BLACKIE & SONS)

FIG. 2.—CLERK 2-STROKE CYCLE INTERNAL COMBUSTION ENGINE

this is the *exhaust stroke*. This cycle is now repeated indefinitely and the crankshaft rotates continuously, the crank-pin thus receiving *one* working impulse in each *two* revolutions. In all modern gas engines the inlet valve A is also cam-operated from a half-speed shaft.

In the four-stroke cycle engine the utilization of the same cylinder alternately as a charging pump and as a power cylinder though very convenient as a simplification in construction involves the serious drawback of only one working impulse in every four piston strokes, and accordingly in single-cylindere or few-cylindere gas engines the crankshaft rotation can only be kept at a tolerable degree of uniformity by providing one, or frequently two, massive fly-wheels which by their great angular momentum maintain the rotation rate only slightly impaired during the exhaust, suction and compression periods.

The Clerk Cycle.—Attention was in consequence soon concentrated upon providing some means of increasing the frequency of the working impulses in gas engines, without sacrifice of economy, and as early as 1878 Sir D. Clerk had produced his first *two-stroke*, or "Clerk cycle" engine, of which an improved example was shown at the Paris Electrical Exhibition of 1881. The operation of this engine (fig. 2) was as follows:—The engine comprises two cylinders, viz., a power cylinder A and pump cylinder B, each containing a piston as shown. The power cylinder A has at its outer end a ring of exhaust ports EE' which are overrun by the piston C when near the end of its out-stroke. The piston D of the pump cylinder B is driven by a crank set of about 90° in advance of the power crank and on its out-stroke sucks into B a charge of mixed gas and air through a sliding valve H and pipe W. At the commencement of D's in-stroke, H being closed, compression of the charge in B begins, and as soon as the pressure rises above that in the power cylinder A, it is delivered into the combustion chamber G of the power cylinder through an automatic inlet valve, the power piston C being then at the end of its out-stroke, as shown. On its in-stroke C first masks the ports EE' and next,—the automatic inlet immediately closing,—compresses the thus entrapped fresh charge into the combustion chamber G. At the inner dead point the compressed mixture is exploded and the piston is driven forcibly downwards, thus performing the working stroke; the expanded and burnt gases rush out into the atmosphere immediately the piston uncovers the ring of ports EE'. It is clear, then, that in this engine every out-stroke of C is a working stroke, and thus the design provides one impulse in every revolution, and so has double the impulse-frequency of the four-stroke cycle.

An ideal two-stroke, or Clerk, cycle engine accordingly should develop twice as much power as a four-stroke engine of the same size and speed. In practice, however, the two-stroke cycle possesses certain features which prevent the ideal performance being attained; these are:—(1) In the four-stroke engine the inlet valve is opened just before the end of the piston in-stroke and

remains open throughout the whole of the suction stroke and usually for a short period thereafter, so that cylinder-charging continues during about 220° of crank-shaft revolution. But in the two-stroke cycle engine the charging period is only the short interval elapsing between the un-covering and re-covering of the ports EE' by the piston, which usually occurs during some 80° of crank shaft revolution. Hence in the two-stroke engine it is in general impossible to get so large a charge as in the four-stroke.

(2) In the four-stroke engine, discharge continues throughout the whole of the exhaust stroke (and in practice even longer), and thus the residual burnt gases are definitely expelled by the piston during its exhaust in-stroke so that, finally, only the combustion chamber remains filled with residual burnt gas, and this often at somewhat less than atmospheric pressure. But in the two-stroke engine the whole cylinder remains filled with hot residual exhaust gases which, while assisted in their exit by the incoming cool fresh charge, *heat* this fresh charge, so expanding it and thus reducing its density and so further diminishing the "volumetric efficiency" of the engine.

(3) Loss of fresh charge frequently occurs by "short circuiting" through the exhaust ports, and many small two-stroke cycle engines suffer some loss of unburned gas from this cause. Clerk cycle engines have been practically superseded in small sizes by the Day engine next described, though a modern example of a small Clerk cycle design appears in the "Dolphin" petrol engine, an account of which is given in *The Gas, Petrol & Oil Engine*, vol. ii. But in the largest types of two-stroke gas engines the Clerk cycle prevails, with some modifications, as in the well-known Koerting and Oechelhauser designs referred to later.

The Day Engine.—A valuable simplification of the Clerk cycle engine was made in 1891 by Day who ingeniously dispensed altogether with the charging pump B (fig. 2) by adapting the crank chamber to perform its service; the Day engine is illustrated in fig. 3 in two forms, that on the left showing the "two-port" type as used in the well-known "Bolinders" marine oil engine, while that on the right illustrates the "three-port" type as universally employed in the small high-speed two-stroke engines of motor bicycles, launches, etc.

In each of these the crank-chamber is completely enclosed so as to be air-tight. In the two-port type the ascending piston creates a partial vacuum in the crank-chamber and the charge of fresh mixture at once enters through an automatic valve as indicated. On the down-stroke this valve at once closes and the mixture is compressed in the crank-chamber to a few lb. per sq.in. pressure; when near the bottom of its stroke the piston first over-runs the exhaust port (on right), the expanded and burnt gases above it at once rushing out through the exhaust, and immediately afterwards over-runs an inlet port (on left) communicating with the crank-chamber, thus permitting a charge of fresh mixture to enter the cylinder. A "hump" on the piston deflects the stream of entering fresh mixture upwards and so minimizes loss by short-circuiting through the exhaust port. The piston, rising, first cuts off the inlet and exhaust ports and next compresses the entrapped charge into the combustion chamber where it is fired, and the working stroke next follows as usual. The two-port engine thus requires one valve, but the three-port engine is valveless, and is the simplest form of internal combustion engine possible, the only moving parts being the piston, connecting-rod and crankshaft. Referring to the right-hand diagram of fig. 3, the third port is shown below the exhaust port. When the piston rises the inlet port is closed, and, as before, a partial vacuum is created in the crank chamber; when near the top of its stroke the *lower* edge of the piston over-runs the third port and fresh charge immediately rushes into the crank-chamber. The subsequent descent of the piston first cuts off the charging port and next compresses the fresh charge in the crank-chamber; the remainder of the cycle is as in the two-port type.

These two-stroke engines will obviously run equally well in whichever direction the crankshaft may be started; this property renders their reversal easy—a valuable feature in marine applications.

Simple Theory.—The working substance is usually, for sim-

plicity, regarded as air, conforming strictly to the equation:—

$$pv = cT \quad (1)$$

where p is pressure, estimated in lb./sq.ft.; v is the volume of 1 lb. in c.ft.; c is a constant, having the value of about 53.3; and T is "absolute temperature" in °F and is equal to the ordinary °F plus 460. The action is further imagined as taking place with the same mass of air always within the cylinder, and the

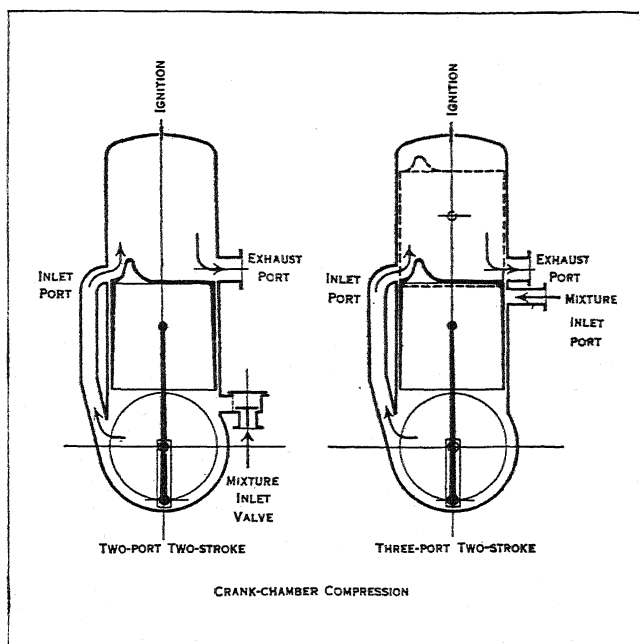

FIG. 3.—DIAGRAMS SHOWING 2-PORT AND 3-PORT 2-STROKE INTERNAL COMBUSTION ENGINES WITH CRANK-CHAMBER COMPRESSION

compression and expansion are regarded as "adiabatic," i.e., no gain or loss of heat to the cylinder walls is contemplated. Fig. 4 exhibits the ideal indicator diagram of a four-stroke cycle engine with these simplifying assumptions.

Imagine the piston as at the top of its stroke with the combustion chamber volume filled with air; this is represented by the point O on the diagram, the combustion chamber volume being v_0 and the atmospheric pressure p_0 . The piston next performs the suction stroke and the corresponding line or is traced on the diagram; at 1 the whole cylinder volume, v_1 , is filled with air at atmospheric pressure (p_1). The return of the piston next compresses the air into the combustion chamber, the rise of pressure with diminution of volume being represented by the (adiabatic) compression curve 1-2. At the end of the compression in-stroke the mixture is exploded and an instantaneous rise of pressure occurs from T_2 to T_3 ; next follows the working out-stroke and the exploded gases expand (again adiabatically) as indicated by 3-4. At the end of the working stroke the exhaust opens suddenly and the burnt charge rushes out, the pressure falling instantly to that of the atmosphere, as indicated by 4-1. Then during the return exhaust in-stroke of the piston the line 1-0 is traced. This cycle is then repeated indefinitely.

In theory the working air is regarded as receiving a sudden accession of heat at 2 which causes its temperature (absolute) to rise from T_2 to T_3 , and a sudden withdrawal of heat at 4, whereby its temperature is reduced from T_4 to T_1 . During the periods of adiabatic compression and expansion no loss or gain of heat is considered to occur. Thus the only heat *given* to the working air per cycle is during the explosion 2-3, and the only heat *subtracted* is that during the "exhaust drop" 4-1. The difference between the heat given and the heat subtracted, or "rejected," is the (heat equivalent) of the mechanical work done by the piston per cycle. Accordingly as both heat exchanges take place at constant volume, if K_v denote the specific heat of the working air at constant volume we have:—

$$\text{Heat given per cycle} = H = K_v(T_3 - T_2) \quad \text{B.Th.U.}$$

$$\text{Heat rejected do.} = R = K_v(T_4 - T_1) \quad \text{B.Th.U.}$$

Work done per cycle $= H - R = K_v(T_3 - T_2) - K_v(T_4 - T_1)$.
(B.Th.U. = British Thermal Unit, the heat required to raise 1 lb. of water 1° F.) and thus:—

$$\text{The Thermodynamic Efficiency} = \frac{H - R}{H} = 1 - \frac{R}{H} = 1 - \frac{T_4 - T_1}{T_3 - T_2} \quad (2)$$

This equation expresses the efficiency in terms of the absolute temperatures at the four corners of the diagram; it is much simplified in the following manner:— The ratio $\frac{v_1}{v_2}$, termed the adiabatic compression ratio, is always known, and is denoted by r ; then $r = \frac{v_1}{v_2}$, and it will also be observed that in the four-

stroke engine r is also equal to $\frac{v_4}{v_3}$,—the ratio of adiabatic expansion. Now it is easily shown in thermodynamics that along an adiabatic curve of a perfect gas the product $Tv^{\gamma-1}$ is constant where γ is the ratio of the specific heat of the gas at constant pressure to the specific heat at constant volume. So that, from fig. 4 in this case:—

$$T_2 v_2^{\gamma-1} = T_1 v_1^{\gamma-1} \quad \therefore T_2 = T_1 \left(\frac{v_1}{v_2} \right)^{\gamma-1} = T_1 r^{\gamma-1}$$

$$T_3 v_3^{\gamma-1} = T_4 v_4^{\gamma-1} \quad \therefore T_3 = T_4 \left(\frac{v_4}{v_3} \right)^{\gamma-1} = T_4 r^{\gamma-1}$$

Substituting these values for T_2 and T_3 in (2) gives:—

$$\text{Thermodynamic Efficiency} = 1 - \frac{T_4 - T_1}{T_4 r^{\gamma-1} - T_1 r^{\gamma-1}} = 1 - \left(\frac{1}{r} \right)^{\gamma-1}$$

and accordingly the expression takes the very simple form:—

$$\text{Thermodynamic Air Efficiency} = 1 - \left(\frac{1}{r} \right)^{0.4} \quad (3)$$

as for air $\gamma = 1.4$ roundly, in the simple theory here set out.

A committee of the British Institute of Civil Engineers in 1905 recommended the adoption of this expression to indicate the ideal maximum thermodynamic efficiency of the four-stroke engine; it is known as the 1905 Air Standard, and has been very extensively

FIG. 4.—IDEAL "OTTO" OR 4-STROKE CYCLE DIAGRAM

employed. It makes the ideal maximum efficiency increase with the compression ratio, as is shown by the following figures:—

For $r =$	4	6	8	10	12	14
The air std. =	.426	.512	.565	.602	.630	.652

In spite of the simplifying assumptions involved it has very well served its purpose; thus, after very extended experience Ricardo, *The Automobile Engineer*, 1928, observed, "As we raise the compression ratio of an engine we improve both the power output and the efficiency very nearly in proportion to the increase in the Air cycle efficiency."

Estimation of Horse-power.—The smaller-powered quicker

running classes of gas engine are usually tested for power by some form of brake dynamometer by which the "brake" or "effective" horse power is directly determined. With larger engines indicator diagrams (see fig. 4) may be taken from the working cylinder; the average height of the figure 1234, measured by the scale of pressures of the diagram, gives the mean effective pressure on the piston in lb./sq.in. during the working stroke; this is usually denoted by p .

Now let d denote the piston diameter in inches, s its stroke in inches, and n the number of revolutions of the crankshaft per minute. Then the piston area is $.7854 d^2$ square inches, and therefore the mean effective piston load during the working stroke is $.7854 d^2 p$ lb. weight.

This load works through $\frac{s}{12}$ feet; and accordingly the "indicated work" performed per working stroke is $.7854 d^2 p \times \frac{s}{12}$ foot-lb. In one hour $60 \times \frac{n}{2}$ working strokes are made and, assuming them all exactly alike, the total indicated work per hour is thus $.7854 d^2 p \times \frac{s}{12} \times 60 \times \frac{n}{2}$ foot-lb.

But a horse-power is, by definition, a rate of working of 33,000 foot-lb. per minute, or $60 \times 33,000$ foot-lb. per hour; finally, therefore the indicated horsepower of a single-cylindered single-acting four-stroke cycle internal combustion engine is expressed by: $\frac{.7854 d^2 p s n \times 60}{12 \times 2 \times 60 \times 33,000}$; and this reduces by ordinary arithmetic to:—

$$\text{Indicated H.P.} = .992 d^2 p s n \times 10^{-9}. \quad (4)$$

If the engine have N cylinders, the total I.H.P. is obviously N times as great as (4).

Suppose that by test both the I.H.P. and B.H.P. of an engine have been ascertained. Then their difference, viz., I.H.P. — B.H.P. is the horse-power absorbed in engine friction and in doing any other work incidental to the performance of the cycle of the engine. Their ratio, viz., $\frac{\text{B.H.P.}}{\text{I.H.P.}}$ is termed the "mechanical efficiency" of the engine and is usually denoted by η ; thus:—

$$\text{Mechanical Efficiency} = \eta = \frac{\text{B.H.P.}}{\text{I.H.P.}}. \quad (5)$$

The product ηp , i.e., mechanical efficiency multiplied by indicated mean effective pressure, is termed the "brake mean effective pressure."

The mechanical equivalent of one B.Th.U. is 778 ft.-lb. of work; and accordingly the heat equivalent of one horse-power-hour is $\frac{33,000 \times 60}{778} = 2,545$ B.Th.U. Suppose, for example, trial

of a gas engine to show that 15 cu. ft. of coal gas was consumed per I.H.P. hour, the gas having a heat value of 500 B.Th.U. per cu. ft. Then $15 \times 500 = 7,500$ B.Th.U. of heat are expended in obtaining 2,545 B.Th.U. of indicated work; and thus the absolute indicated thermal efficiency = $\frac{2,545}{7,500} \times 100 = 33.9\%$.

If the mechanical efficiency of the engine has been found to be 85%, so that $\eta = 0.85$, then the brake thermal efficiency would be $33.9 \times 0.85 = 28.8\%$. If the ratio of compression, r , of the engine were 6, the corresponding ideal air standard efficiency would be 51.2%. And accordingly the relative indicated thermal efficiency = $\frac{33.9}{51.2} \times 100 = 66.2\%$. Similarly the relative brake thermal efficiency = $\frac{28.8}{51.2} \times 100 = 56.25\%$. These figures are from

actual test results from a well-designed 100 B.H.P. gas engine in 1923. The small gas engine is rarely as efficient as the large one, contrary to the steam engine.

GAS ENGINE PROGRESS

Fuels Used by Gas Engines.—The principal are:—(1) Town's gas; often styled "coal gas." (2) Producer gas. (3) Coke oven gas. (4) Blast furnace gas. (5) Natural gas.

For a description of these, see FUEL; GAS MANUFACTURE; NATURAL GAS.

The table following gives some average values of these fuels and data relating to their employment for power purposes in gas engines:—

TABLE I. Gas Engine Fuels; average heat values

Fuel	Heat value in B.Th.U. per c.ft. at 1 Atm and 60° F.	Minimum vol. of air, c.ft. required per c.ft. of fuel	Maximum heat evolved on combustion of 1 c.ft. of mixture B.Th.U.
Town's gas	500	5.5	77
Coke-oven gas	400	4.0	80
Producer gas (from anthracite or coke) . .	130	1.0	65
Blast-furnace gas . . .	100	0.75	57
Natural gas	950	9.5	90

To avoid overheating the engine it is in practice found necessary to provide a considerable *excess* of air in order to reduce the heat evolved per cu.ft. of mixture used to form 50 B.Th.U. in the smaller types to 35 B.Th.U. in the largest. This practical limitation prevents advantage being taken of the high heat-evolution per cu.ft. of Town's gas, coke-oven gas and natural gas, and furnishes the reason for the suitability of so poor a gaseous fuel as blast-furnace gas.

Ignition.—The ignition of the charge in gas engines with certainty and regularity proved for long a difficult problem first successfully solved by the Barnett (flame) igniting cock (1838), already mentioned, which continued in use up to about 1892. A method very widely used up to about 1923, particularly in small-powered gas engines, was that known as "hot-tube" ignition; it was first employed in the Stockport gas engine in 1883 and in its simplest form it consisted merely of a metal tube, usually of iron or nickel, a few inches long, closed at its outer end, screwed into the end of the engine cylinder, its open inner end being in constant communication with the contents of the combustion chamber ("open-tube" ignition). The tube was continuously heated during working by an external Bunsen-flame lamp, and explosion of the engine charge occurred as soon as the compressed fresh mixture reached its red-hot portion. Tube ignition proved quite satisfactory for engines of up to about 20 horse-power.

Modern gas engines are almost universally fitted with electrical

FIG. 5.—CROSSLEY HORIZONTAL GAS ENGINE; SECTIONAL VIEW

ignition, commonly of the low tension magneto type wherein a magneto with a rocking armature provides current to a low-tension make-and-break ignition plug fitted to the combustion chamber of the cylinder. High tension magneto ignition, substantially as used in all petrol engines, though of robust type, is also becoming more general; thus in 1922 the gas engines of, *inter alia*, the National, Campbell, and Browett-Lindley companies were fitted with H.T. ignition.

Starting of Gas Engines.—For engines of less than about 30 H.P. no special starting apparatus is usually needed; having

retarded the ignition, and turned on the gas supply, the fly-wheel is turned by hand as quickly as possible and the engine thus started.

Many gas engines of 30–200 H.P. are started by aid of a small pump fitted to the engine by which an initial charge of gas and air is delivered by hand-power into the combustion chamber, and ignited by “flicking over” the L.T. magneto by hand; many flywheels are furnished with a ring of holes round the rim for insertion of a crow-bar, by which the engine may be “barred” round so as to get the crank-pin in a favourable position for starting, *i.e.*, about 20° beyond the inner dead centre on the firing stroke. Large gas engines are started by compressed air stored in cylindrical steel reservoirs at a pressure of 100–300 lb. sq.in. The air compressor is sometimes belt-driven from the engine, but in very large engines is a separate unit driven by a small auxiliary engine. A special air-starting valve is fitted to the combustion chamber of the cylinder, and on admission of the compressed air through this the engine commences to turn, and takes up its working cycle after a few revolutions.

Modern Gas Engines.—In gas engines of less than about 400 H.P. but little essential change has occurred since 1910; there is a steady output by many builders of repute of a nearly standard type of horizontal four-stroke cycle single-acting one- or two-cylindrical engine using Town's gas or producer gas as fuel. A normal engine of this type, by Crossley Bros. is shown in fig. 5, comprising a water-jacketed cast iron cylinder fitted with a gas-tight cast-iron piston driving a crankshaft in the usual manner by means of a connecting rod. The very massive flywheel will be noted; in this case it is formed with an internally-toothed ring and by means of the hand-wheel and enmeshed pinion shown “barring” round before starting is effected. At the closed end or “breach end” of the cylinder is the combustion chamber containing at the top the mixture inlet valve and at the bottom the exhaust valve both, of course, cam-operated from the half-speed shaft. Ignition is by low-tension (L.T.) magneto. The engine speed is regulated by a governor which varies the lift of the inlet valve.

Vertical Gas Engines.—The considerable bulk and weight of the horizontal slow-running larger gas engine has caused attention to be given to faster-running multiple-cylindrical inverted-vertical designs, occupying much less floor area, and of diminished size and weight. Prominent among British builders of this type is the National Gas Engine Co. whose designs range from a four-cylinder, two-crank, single acting four-stroke inverted vertical tandem engine of 300 B.H.P. at 300 rev. per minute, to a 12-cylinder six-crank similar design of 1,500 B.H.P. running at 200 rev. per

The *tandem double-acting four-stroke engine* possesses the important advantage that every stroke is a working stroke. A view of a 2,500 Horse-power M.A.N. engine, in part section, is shown in fig. 6. The two liberally water-cooled cylinders A, A', are in line with their water-cooled pistons mounted on a common piston-rod (also water-cooled), to one end of which is attached the connecting-rod C driving a single-throw crankshaft D. The

FIG. 7.—SECTION OF 600 B.H.P. KOERTING ENGINE CYLINDER

three crossheads EEE are adjusted to carry the weight of the piston rod and also of the two heavy pistons, so that these “float” in the cylinders, thus greatly reducing engine friction and consequent wear. The inlet valves will be noted at the top, and the exhausts at the bottom, of each cylinder. To illustrate performance:—Eight engines of this type by Vickers had each a cylinder bore of 43.3 in., a stroke of 47.3 in. and, using blast furnace gas, developed roundly 1,800 B.H.P. at a speed of 100 rev. per minute. One of the largest installations of M.A.N. engines is a 65,000 horse-power plant at Bruckhausen. The type is very reliable and economical; a 2,000 H.P. engine using blast furnace gas has run, day and night, during 19 months. In 13,870 consecutive hours the engine actually ran during 13,687 hours, *i.e.*, 98.6% of the whole time possible; and the stoppages were due to the blast furnace, and not to the engine.

Large Two-stroke Gas Engines.—The large two-stroke Clerk cycle engine has proved very successful, particularly in the horizontal designs of Koerting & Oechelhauser.

The Koerting is a single-cylindrical double-acting horizontal two-stroke engine, and the piston thus receives a working impulse in every stroke. A sectional view of a Koerting cylinder appears in fig. 7. The engine is characterized by the long water-cooled piston AA,—of length fully half that of the cylinder; in its extreme right and left positions the piston over-runs a central belt of exhaust ports BB, and so permits the escape of the burnt gases into the exhaust branch C. At each end of the cylinder is a mechanically operated inlet valve D, D'. The illustration shows the contents of the right-hand end of the cylinder exhausting through BB; simultaneously the inlet D' is opened admitting firstly air only, and immediately afterwards the working charge of mixed gas and air. The preliminary air is a scavenging charge; the working charge is delivered to the inlet valve boxes by separate double-acting pumps driven by the engine and no mixture of gas and air occurs until they jointly enter the working cylinder; this is an important point in relation to large gas engines. The piston now moving towards the right first cuts off the exhaust ports BB and next compresses the mixture into the combustion chamber where it is fired (by L.T. magneto) as usual, the resulting explosion driving the piston towards the left. The same cycle of operations is performed in the left-hand end of the cylinder, and thus *every stroke* of the piston is a working stroke. Starting is effected by compressed air stored at 150–300 lb./sq.in.; the air starting valves are shown at EE in fig. 7.

The Siegner Co. have built Koerting engines giving 2,000 horse-power from a single cylinder of 42 in. bore and 55 in. stroke, running normally at 80–90 revs. per minute. The inlet valves of these very large engines were 19.7 in. in diameter, with a lift of 3.14 in. The American de la Vergne Co. have installed at Buffalo

FIG. 6.—LARGE HORIZONTAL GAS ENGINE. A 2-CYLINDER, DOUBLE-ACTING, 4-STROKE, SINGLE-CRANK NUREMBERG ENGINE

minute. One “National” installation of this type aggregates 11,500 horse power.

Large Gas Engines.—From about 1910 improvement in the largest types of gas engine have been mainly in matters of detail as, *e.g.*, in the more extended use of refuse material as fuel for the gas producers: in the employment of high tension electrical ignition: and in better cooling and governing arrangements.

The large horizontal slow-speed engine is typified by the four-stroke double-acting tandem design as developed by the Nuremberg (M.A.N.), Ehrhardt, Deutz, and Haniel companies in Europe, and built also in Great Britain by the Lilleshall Co., Vickers and Galloways.

Koerting-type engines aggregating 40,000 B.H.P. Upwards of 250,000 B.H.P. of Koerting engines had been constructed in 1923.

The Oechelhauser Engine.—This successful large two-stroke gas engine works on a modified Clerk cycle; a diagrammatic view appears in fig. 8. The engine is of the horizontal single-acting type having a cylinder AA open at both ends, containing two pistons BB¹ working in opposite directions, and driving a common three-throw crankshaft. B drives the central crank through an ordinary connecting rod, while B¹ is fitted with a short piston rod R terminating in a crosshead Q fitted with side rods PP¹ and return connecting rods MM¹ driving the two side cranks. The combined gas and air pump HH is also driven from the crosshead Q as indicated. Just before it reaches its extreme "out" position piston B over-runs the ring of exhaust ports C; at the same time piston B¹ over-runs firstly the ring of air inlet ports D and immediately thereafter a second ring of gas ports E. The exhaust gases at once escape through C, assisted by the scavenging charge of air under slight pressure entering through D. This fresh air also cools any residual exhaust gas, so minimizing risk of pre-ignition, and preventing loss of fresh fuel through the exhaust when the gas ports E open. The pistons next approach one another and compress the entrapped fresh charge between them; at the end of the "in," i.e., compression stroke, the mixture is fired electrically and the working out-stroke then follows. The engine thus furnishes one impulse per revolution. The double-acting pump H is an air-pump on one side of its piston and a gas-pump on the other; gas and air are pumped separately into the reservoirs L and K respectively, in which a pressure of 5-6 lb./sq.in. is maintained. It will be noted that the gas and air are only mingled actually within the working cylinder. Oechelhauser engines to Messrs. Beardmore's designs range from 400 horse power at 130 rev. per min., with cylinder 24 in. bore and stroke of 30 in., to 2,500 horse power at 80 rev. per min., with cylinder bore of 48 in., and stroke of 60 in.

The Fullagar Engine.—A valuable advance in the double-piston Oechelhauser type of engine was made by H. F. Fullagar about 1912. By associating together two open-ended cylinders he dispensed with the somewhat cumbersome side-rods and return connecting-rods of the Oechelhauser design, and also was able to use a normal flat two-throw crankshaft. In this way weight and cost were saved and a very compact engine, giving two impulses per revolution, resulted. The essential feature of the Fullagar power unit is a pair of side-by-side open-ended cylinders with their pistons connected across by special diagonal tension rods; the obliquity of these rods is not great, and the side-thrusts arising therefrom are borne by crossheads and (water-cooled) guides. The compressed power charge between, say, pistons A and B being fired, B is driven downwards thus actuating the left-hand crank, while A is driven upwards, thus simultaneously actuating the right hand crank through a tension rod; hence as the result

FROM GLAZEBROOK, "DICTIONARY OF APPLIED PHYSICS" (MACMILLAN & CO.)

FIG. 8.—DIAGRAM OF THE 2-STROKE DOUBLE-PISTON OECHELHAUSER ENGINE

of each working impulse the crankshaft experiences a nearly simple "torque"; moreover, the cylinders being open-ended, no stresses are set up in the engine-framing during running; thus the Fullagar engine may be built somewhat light for its power output. As described here, the charges of gas and air are as if supplied by pumps formed by boxing in the top crossheads; the charge is delivered at a pressure of about 3 lb./sq.in. As with other two-stroke cycle engines, the Fullagar may be run in either direction by giving it the necessary initial motion, and suitably timing the ignition.

An early experimental engine of 550 B.H.P. by Allen of Bedford comprised two Fullagar units with cylinders of 12 in. bore, and each piston with a stroke of 18 in.; normal speed 250 rev. per min. A 30-hour trial of this engine showed an absolute thermal indicated efficiency of 37.6%; the weight of the engine was only 87.5 lb. per B.H.P. which is small for a stationary design. A 2,000 horse-power engine by Belliss and Morcom in 1918 comprised three Fullagar units, with 18 in. cylinders and 27 in. stroke, running at 170 rev. per minute. This engine used as fuel coke-oven gas having a net calorific value of 440 B.Th.U. per c.ft. and tests showed a full-load consumption of roundly 22½ c.ft. of gas per B.H.P. hour, corresponding to an absolute brake thermal efficiency of 26%. The Fullagar engine also uses oil fuel in the Diesel manner, and marine Fullagar-Diesel engines are constructed by Cammell Laird and others in sets of 3,000 B.H.P. and over.

HEAVY OIL ENGINES

The success of the Otto and Langen engine, described above, and the final establishment of internal combustion engines on a commercial basis by the Otto silent gas engine of 1876, directed the close attention of many engineers to improving further such engines particularly in relation to the fuels employable. Town's gas was an expensive fuel, and available only in large centres of population. The increasingly wide distribution of petroleum oils, particularly the paraffin oils, lamp-oils, or kerosenes, no doubt suggested that if such oils could be rendered available as fuel a much wider area of usefulness would be opened to the internal combustion engine. The earliest of such engines to achieve a considerable measure of success was the Priestman Oil engine introduced in 1885.

Heavy Oils.—This is a general name for inflammable liquid hydrocarbons, particularly petroleum, of flash point exceeding about 75° F and ranging in specific gravity from 0.78 to 1.0; with such liquids a considerable preliminary heating is necessary to obtain an explosive mixture of their vapour with air, and the earliest heavy oil engines were accordingly of the vapourizing class, and used as fuel American and Russian kerosenes, Scotch paraffin and shale oils, and even crude and residual petroleum oils.

The Early Priestman Oil Engine.—This engine was built (1885) in four-stroke cycle single-cylindere types up to 11 horse power, and gave best results when using as fuel kerosenes of 0.8 sp.gr. and flash point about 100° F. The oil fuel was delivered by air pressure through a minute orifice, in the form of a very fine spray or mist, into an exhaust-heated vessel or "vapourizer," where it immediately became gaseous; in this condition, during the suction stroke of the engine, it entered the cylinder together with a correct proportion of air drawn in through an automatic valve; this mixture was then compressed and fired and the working stroke followed as usual. To start the engine the vapourizer received a preliminary heating from a blow-lamp; a small hand-pump then furnished air for the initial spraying of the fuel into the vapourizer; the flywheel next being turned by hand, the engine started running. As soon as all was well warmed up, the blow-lamp was extinguished, the engine exhaust thereafter maintaining the vapourizer at its necessary high temperature. A test of a 4.5 horse-power, 8.5 in. bore × 12 in. stroke × 180 rev. per min., Priestman engine in 1890, using as fuel Broxburn lighthouse oil of .81 sp.gr. and flash point 152° F, showed a consumption of 1.243 lb. of oil per B.H.P. hour. In later tests (1892) of an engine of the same size, running at 204 rev. per minute, and using as fuel Royal Daylight oil of .79 sp.gr. and flash point

77° F, the consumption was reduced to 0.842 lb. per B.H.P. hour. The pressure of compression in these tests was 35 lb./sq.in., and of explosion, 151.4 lb./sq.in. above atmosphere; and the total heat value of the Royal Daylight oil was stated to be 21,490 B.Th.U. per lb.

Gardner Paraffin Engine.—Priestman was quickly followed by other inventors, as Griffin, Samuelson, Thornycroft, etc., who used exhaust-heated vapourizers, and by Gardner, Howard, Smith-Dudbridge, Crossley, etc., who used lamp-heated vapourizers. In the earlier Gardner paraffin engines, for example, the paraffin was supplied, either by gravity or under pressure, to the "mixer" diagrammatically shown in fig. 9. The paraffin, entering through K, passed into the small duct D through a hand-regulated needle-valve N. The air entered through the branch A. The spring-supported disc, V, borne on a spindle terminating upwards in a needle valve P automatically closed the fuel supply when the engine ceased running. The branch C communicated with the lamp-heated vapourizer.

FROM CLERK AND BURLS, "GAS, PETROL AND OIL ENGINE" (LONGMANS, GREEN & CO.)
FIG. 9.—EARLY GARDNER PARAFFIN "MIXER"

During each suction stroke of the engine, air drawn in through A depressed the disc V, so permitting delivery of a sprayed charge of fuel through D. The mixture of the air and fuel-spray next passed via C into the vapourizing vessel which was continuously heated by an external Bunsen-flame oil lamp. As fuel it was found practicable to use kerosenes of .825 sp.gr. and up to 200° F flash (by close test). Four-stroke vapourizing engines of this type were built having from 1 to 8 cylinders, and developing from 5 to 200 horse-power.

In the vapourizer, heavy oil fuels were rendered gaseous, mixed with a suitable volume of air, admitted to the cylinder and then exploded exactly as in an ordinary gas engine. Simple though this would be were heavy oils hydrocarbons of one definite chemical composition, it has proved practically troublesome with actual heavy oils, which are in general composed of a mixture of many different liquid hydrocarbons, boiling at temperatures ranging from 200° F to 600° F; thus completely to vapourize such fuel its temperature must be raised at least to 600° F. But at this high temperature the lighter constituents of the fuel are liable to be "cracked," i.e., decomposed into free hydrogen and carbon; the carbon deposits in the vapourizer, in time choking it up. In practice a fuel temperature in the vapourizer of about 500° F was found to be the best to use. This necessary pre-heating of the fuel involved three serious disadvantages:—(1) The fresh charge of air and vapour being heated before entering the cylinder, had expanded thus reducing the mass of the charge, and hence the power output of the engine. (2) The fresh charge being heated, only a low compression ratio, usually 3.0 to 3.5, could be employed in order to avoid detonation and pre-ignition troubles. (3) The use of a low compression ratio kept the thermodynamic efficiency of such engines low.

Accordingly although the heat value of kerosene usually somewhat exceeds that of petrol, vapourizing oil engines designed to use either fuel usually give only some 85% of their maximum power output with paraffin, and show a reduced economy.

In small powers (5 H.P. or so), vapourizing engines are still used to a small extent for domestic lighting and light agricultural work, but are rapidly being replaced (a) by the much more cleanly and convenient small petrol engine, and (b) by more modern and simple heavy oil engines as described later herein.

The Hornsby-Akroyd Oil Engine.—An important simplification in the working of heavy oil engines was effected by Akroyd

Stuart (1886–90) who succeeded in dispensing both with a separate vapourizer and also with all ignition apparatus. The famous Hornsby-Akroyd oil engine was the first to utilize successfully the heated wall of a special portion of the combustion chamber to effect both vapourization of the fuel and the automatic ignition at the correct instant of the working charge. A sectional view illustrating this engine appears in fig. 10 which shows an ordinary single-acting horizontal four-stroke cycle internal combustion engine but with an extension A, termed the "hot bulb" attached to the end of the combustion chamber, communication between them being by a relatively small passage B.

The action is as follows:—The hot bulb receives a preliminary heating from an external blow-lamp; the engine flywheel being next turned by hand, the piston during the suction stroke draws a charge of air directly into the cylinder through an air inlet valve; at the same time the charge of oil is delivered by the small force-pump into the hot bulb where it vapourizes and the vapour, mixed with residual exhaust gas from the previous cycle thus fills the bulb, the cylinder containing air alone. On the compression stroke of the piston the air passes through the narrow passage B into the bulb and then mixes with the oil vapour; the mixture is at first too rich to ignite, but the engine is so adjusted that just as the compression is completed a correct mixture is attained; the heat of the hot bulb then causes automatic ignition, and the resulting pressure drives the piston outwards, thus performing the working stroke. The bulb temperature is maintained by heat derived from successive explosions during running. After prolonged heavy-load running the bulb tends to become too hot, which causes pre-ignition of the charge, and also "cracking" of the oil, with resulting deposit of "coke"; on the other hand if the engine be run light for some time the bulb tends to become too cool to ignite the charge. A suitable bulb temperature is maintained by varying the supply of cooling water to the jacketed forward end of the bulb by means of the hand-controlled valve C. With reference to the automatic ignition of the charge, Sir D. Clerk observes (*The Gas, Petrol and Oil Engine*, vol. ii.):

"It is a peculiar fact that oil vapour mixed with air will explode by contact with a metal surface at a comparatively low temperature, and this accounts for the explosion of the compressed mixture in the hot bulb A, which is never really raised to a red heat. It had long been known to engineers conversant with gas engines that in certain conditions of the internal surface a gas engine will run and ignite with great regularity without any special form of ignitor, if only some portion of the interior surface of the cylinder or combustion chamber be so arranged that its temperature is moderately raised. Although that temperature may be too low to ignite the mixture at atmospheric pressure, yet when compression is complete the mixture will often ignite quite regularly."

FROM CLERK AND BURLS, "GAS, PETROL AND OIL ENGINE" (LONGMANS, GREEN & CO.)
FIG. 10.—EARLY HORNSBY-AKROYD OIL ENGINE

In an old early two-stroke cycle engine (circa 1880) Clark screwed a bolt into the end of the piston, the bolt being long enough to project well into the explosive charge. After running the engine for about 15 minutes in the usual way he found that if the flame-igniting device were put of action the engine still continued to run regularly, the mixture being fired by the heated end of the bolt which caused ignition just as the mixture became fully compressed; in this case, however, the bolt attained a high red heat. Later, "hot-bolt" ignition was for a time used in some oil engines by, e.g., Clayton and Shuttleworth and Crossley.

Test of a single-cylindere 32. B.H.P. Hornsby-Akroyd engine in 1903 gave results as follows:—

Compression pressure, 85 lb./sq.in.

Explosion pressure, 260 lb./sq.in.

Lbs. of fuel used per B.H.P. per hour (full load), 0.613.

The fuel used was "Russolene" oil having a sp. gr. of .82, a flash point of 88° F (close test), and a heat value of 18,450

FIG. 11.—PETTER "C" TYPE HEAVY OIL ENGINE

B.Th.U. per lb.; the Brake Thermal Efficiency was therefore

$\frac{2545}{613 \times 18450} \times 100 = 25.5\%$. The engine ran at 230 rev. per minute.

Many other "hot bulb" engines soon appeared, *e.g.*, the Blackstone, Crossley, National, Robey, Petter, Ruston, etc. Thus, in the Crossley Lampless oil engine, the oil is vapourized by injection into a hot bulb forming a prolongation of the combustion chamber; ignition is, however, here effected automatically by a hot tube which projects into the bulb and is maintained at the high temperature necessary to cause ignition by heat derived from the successive explosions; many early hot-bulb engines were similarly fitted. During prolonged running at heavy load a small spray of water could be injected into the exploded mixture through the "water sprayer"; the practice of water injection was at one time somewhat extensively adopted, but it is preferable to avoid it if possible.

Numerous hot-bulb engines have appeared since about 1886 varying only in the details of vapourization of the fuel, their mode of operation being, in general, not essentially different from that of Akroyd Stuarts' engine.

SEMI-DIESELS

Appearance of the Diesel engine (*q.v.*) in 1895, with its remarkably low fuel consumption and high efficiency of performance, attracted engineers to the problem of obtaining this low fuel consumption without being compelled to have recourse to the extremely high compression and high-pressure injection-air-blast of

the Diesel, which involve a heavy and costly engine, necessitating great refinement in design and manufacturing processes to ensure satisfactory continuous running.

This problem has been very well solved by combining the hot bulb engine with a moderate compression and airless or "solid injection of the fuel at or about the instant of maximum compression in a large class of engines of both four-stroke and two-stroke cycle, now termed semi-Diesels.

The accepted definition of a semi-Diesel engine is as follows:—

"A semi-Diesel engine is a prime mover actuated by the gases resulting from the combustion of a hydrocarbon oil. A charge of oil is injected in the form of spray into a combustion space open to the cylinder of the engine at or about the time of maximum compression in the cylinder. The heat derived from an uncooled portion of the combustion chamber, together with the heat generated by the compression of air to a moderate temperature, ignites the charge. The combustion of the charge takes place at, or approximately at, constant volume."

By 1928 the great majority of hot bulb semi-Diesel engines operated on the two-stroke cycle, with or without crank chamber compression (*see above*); among the few examples of four-stroke cycle hot bulb semi-Diesels the Ruston and Hornsby "Class M" engine may be noted. These, built in single-cylindere horizontal type from 6 to 40 B.H.P., are run on crude, standard Diesel, or refined oils, and show a consumption from .48 to .6 lb. per B.H.P. hour. The hot bulb receives a preliminary heating by lamp, and the oil fuel is injected by a small force-pump as usual. Starting is effected by hand, or compressed air if preferred. Four-stroke hot bulb semi-Diesels were also then built by Fielding and Platt, and by Tangye; the four-stroke type though more costly to build, is somewhat more economical in fuel consumption than the two-stroke, and requires also in general considerably less oil for lubrication.

The great simplicity, low production cost, and considerable fuel economy of this type caused it to grow rapidly in favour with power users, and among prominent builders in 1928 may be mentioned:—Allen, Babcock, Beardmore, Bolinders, Campbell, Gardner, Marshall, Mirrlees, Petter and Robey.

A typical two-port, two-stroke, hot-bulb, semi-Diesel heavy oil engine with crank-chamber compression (*see above*) is the (Swedish) Bolinders engine as largely used for marine purposes in motor trawlers, etc., which is built in robust four-cylindere designs up to 500 brake horse power. In this engine air enters an enclosed crank-chamber during the up-stroke of the piston through automatic valves, and near the end of the down-stroke, under slight pressure, rushes into, and charges, the cylinder through an inlet port, and assists also in the expulsion of the burnt gases through an exhaust port on the other side. On the succeeding up-stroke the air is compressed to 125–150 lb./sq.in. into the combustion chamber and hot bulb and at the end of compression the fuel pump sprays the charge of oil into the bulb, the explosion automatically following. The hot bulb receives a preliminary heating by lamp, and the engines are started by compressed air.

To reverse the marine Bolinders engine it is slowed nearly to the stopping point, when a special device sprays a charge of oil into the bulb before the piston has quite completed its up-stroke; a premature explosion follows, and reversal of motion takes place, the engine thereafter running equally well in the new direction.

Vickers-Petter Heavy Oil Engines.—These engines are also solid-injection, two-port, two-stroke cycle semi-Diesels with crank-chamber compression, but with the bulb *water-jacketed*, as shown in fig. 11. By extended tests the makers are enabled to obtain automatic ignition of the charge using only a moderate compression pressure, and thus eliminate the *hot-bulb*. These engines are built of single-cylindere 25 B.H.P. type running at 375 rev. per min. to six-cylindere 600 B.H.P. running at 270 revs. per minute, and use as fuel refined, crude and even low-grade residual petroleum oils; the consumption is as low as 0.43 lb. of fuel per B.H.P. hour. Starting from cold is effected by compressed air in about one minute.

Though there is no "uncooled portion of the combustion chamber" in this and the following type, they are still usually classed

by engineers as "semi-Diesels" as the combustion of the fuel is, in general, of the "constant volume" type.

"Cold Starting" Heavy Oil Engines.—Lastly is to be noticed a large modern class of heavy oil engine mostly of four-stroke type in which the bulb is entirely eliminated. The type depends for ignition solely upon the high temperature attained by the air on compression; it employs compression pressures higher

FIG. 12.—INDICATOR DIAGRAMS FROM BLACKSTONE "COLD STARTING" SEMI-DIESEL ENGINE

than those used in the hot bulb class, yet lower than those in the true Diesels; the fuel is sprayed by airless or "solid" injection into the combustion space at, or near, the instant of maximum compression, the resulting combustion being, in general, partly at constant volume and partly at constant pressure. Such are styled "cold starting" engines and are usually included among "semi-Diesels," as in a true Diesel engine the combustion pressure should not rise above the maximum pressure of compression.

This is very well illustrated by fig. 12, which is a reproduction of diagrams taken from a 150 B.H.P. Blackstone cold starting heavy oil engine. It will be observed that the maximum compression pressure was 380 lb./sq.in., while the maximum explosion pressure was 550 lb./sq.in. at full load, and that combustion continued constant at this maximum explosion pressure for a short portion of the working stroke.

Four-stroke cold-starting engines were built in 1928 by, among others, the following prominent British makers:— Blackstone, Campbell, Crossby, National, Premier, Robey, Ruston & Tangye; these were built in units of from 6 to over 300 B.H.P.

The table below shows roughly the progressive increase in fuel economy in heavy oil engines from the introduction of the early Priestman vapourizing paraffin engine of 1885 to the Scott-Still combined Diesel-steam type of 1928:—

TABLE II. Illustrating progressive fuel economy in Heavy Oil Engines

Type	Average fuel consumption in lb. per B.H.P. hour
Early Priestman Vapourizing "Paraffin" engine	1.24 to 0.84
Early Hornsby-Akroyd hot bulb	0.61
Later improved hot bulb engines	0.48 to 0.6
Water-cooled bulb engines	0.43
"Cold Starting" engines	0.41
True Diesel engines	0.39
Still-Diesel-steam engine	0.35

BIBLIOGRAPHY.—The subject of heavy oil engines is a large one, and only a somewhat superficial account can be presented in a short article; readers who wish to proceed further may refer with advantage to some of the following works:—

Pollock, *Hot-bulb Oil Engines* (1919); L. H. Morrison, *Oil Engines* (1919); A. H. Goldingham, *The Design of Oil Engines* (1922); A. W. and Z. W. Daw, *Oil and Gas Power* (1923); A. H. Bird, *Oil Engines* (1923); A. P. Chalkley, *The Diesel Engine*, 6th ed. (1927). See the various engineering and marine journals.

LIGHT OIL (OR PETROL) ENGINES

Few inventions in the short space of a single generation have effected such profound changes in human life as the small high-speed light oil internal combustion engine, more familiarly known

as the "petrol motor." Not only has it completely revolutionized land transport, but it has also rendered popular flight by heavier-than-air machines, and in marine, submarine, industrial, agricultural, and even in domestic life has wrought important and far-reaching changes.

Daimler's Engines.—The principal credit of the invention of this all-important type of internal combustion engine is due to Gottlieb Daimler (1834–1900). Up to about 1883 even the smallest internal combustion engines were extremely heavy weighing as much as 1,100 lb. per horse-power, and running at not more than 200 rev. per min.; Daimler's 1886 engine ran at fully 800 rev. per min., and weighed only 88 lb. per horse-power. An early design by him is illustrated in fig. 13; it is of the normal four-stroke inverted-vertical type with enclosed crank-chamber and "splash" lubrication. Daimler first used the starting handle. The valves will be noted in a pocket on the right of the cylinder, the (automatic) inlet being placed above the cam-operated exhaust; between them is to be seen the platinum open-tube igniter, heated by an external petrol-burning lamp.

In fig. 13 a simple type of float-feed carburetter is indicated, but in the earlier Daimler motors a surface carburetter was used in which warmed air was drawn through a constant thickness of petrol during the suction stroke of the engine.

Thus Daimler's great achievements were (1) The successful

FROM GLAZEBROOK, "DICTIONARY OF APPLIED PHYSICS" (MACMILLAN & CO.)

FIG. 13.—DIAGRAM OF EARLY DAIMLER ENGINE

employment of high revolution speeds enabling bulk and weight to be greatly lessened and power increased, and (2) The successful and safe employment of mixtures of volatile liquid hydrocarbons or "petrols" as fuel. The first Daimler motor-bicycle ran in 1886, and the first Daimler-engined car in 1887. It is curious at the present day to learn that he did not regard favourably the application of his little engine to road vehicles, and that he devoted his attention later to their use in propelling launches and canal boats, in which services they were largely used from 1887 onwards.

But in 1889 Panhard and Levassor arranged for the manufacture of Daimler's engines in France, and progress in automobilism quickly became apparent. Contemporaneously with Daimler, Benz of Mannheim had devoted much attention to the production of a small I.C. engine for road vehicles, and achieved considerable success; as early as 1878 Charles Benz fitted a tricycle with a $\frac{1}{2}$ horse-power motor, and obtained a speed of 7 miles per hour. The early Benz cars, belt-driven by a horizontal four-stroke single- or double-cylindrical rather slow-running engine located in the rear of the vehicle, for some years enjoyed a deservedly high reputation; at the 1889 Paris exhibition a Benz car was the sole representative of automobilism!

Among the early pioneers must also be mentioned de Dion Bouton, who effected substantial advances in motor-car engines from 1895 onwards; these little engines—fitted even then with high tension ignition with non-trembling coil and dry battery—ran very fast and had a notably high power output. The early de Dion $1\frac{1}{2}$ and $2\frac{1}{2}$ horse-power motor tricycles were widely used for several years. Their original engine was air-cooled with the now long familiar finned cylinder and aluminium crank-case, splash lubrication, automatic inlet valve, high tension electric ignition, and ran at 1,500–1,800 rev. per min. The early heavier type cars of Daimler and Panhard were usually driven by two-cylindrical engines of about $3\frac{1}{2}$ in. bore \times 5 in. stroke \times 700 rev. per min., and were fitted with open-tube ignition, with external lamps to keep the tubes hot (see p. 500, GAS ENGINES). Four-cylindrical water-cooled engines largely increased in number from 1902 onwards.

Early estimates of the power required for cars were ludicrously inadequate; even in 1896 the late Sir D. Salomons stated publicly that the horse-power necessary had been raised from four to six; yet, within a very few years cars were running with engines of 60, 80 and even 100 horse-power.

The four-cylindrical four-stroke inverted-vertical single-acting water-cooled engine with cam-operated "poppet" inlet and exhaust valves, H.T. magneto ignition, float-feed carburetter and semi-forced lubrication has now for long been firmly established as the standard petrol motor of the average road automobile.

By 1928 a tendency towards the greater luxury of the six-cylinder-engined car became manifest; a few eight-cylindrical cars were also built; and the Daimler Motor Co. had even put on the market a twelve-cylindrical car, the "30 H.P. double-six." A few successful two-cylindrical small cars were also largely employed in 1928, notably the 7 H.P. "Jowett," and the "Trojan."

Fuels of Petrol Engines.—The change, mainly effected by Daimler, from the heavy slow-running gas engine to the small high-speed light liquid fuel motor proved practically a lengthy task, the choice of a suitable and easily procurable fuel being particularly difficult. It is to be remembered that in his day the petroleum industry was young, and the lighter volatile and highly inflammable constituents of crude oil were regarded as dangerous, and treated mainly as waste substances. The mixture of light hydrocarbons known in Britain as petrol, in America as gasoline and in France as essence, now so largely used consists, for the most part, of the lighter constituents of crude petroleum oils, and ranges in specific gravity from about .68 to .78. The earliest engines "carburetted" their air, *i.e.*, obtained an explosive mixture of air and vapour from the liquid fuel, by passing the air drawn in by the engine on the suction stroke over a series of trays fitted in a closed vessel; the trays were kept supplied with a thin layer of the liquid fuel by a small pump. The air thus became saturated with vapour, and correct proportions of the mixture were obtained before reaching the engine by regulated admission of an additional quantity of fresh air. This was the general principle of the surface carburetter, which survived in a few cases (as, *e.g.*, the Lanchester) even as late as 1910. The insuperable objections to the type were (1) The difficulty of obtaining a correct mixture at varying speeds and temperatures, (2) The lighter constituents of the fuel usually evaporated first, leaving a heavier and relatively non-volatile residuum which was wasted. Hence arose a great demand for a practically homogeneous petrol of about .68 sp.gr., but the rapid growth in the

world consumption soon exhausted available supplies of this very light spirit.

Maybach's famous "float-feed" carburetter, invented in 1893, was, however, found to supply a completely satisfactory practical solution of the problem of using successfully much heavier grades of petrol, and this, in numerous improved forms, is in universal use at the present time. A diagrammatic illustration of this cele-

FROM CLERK AND BURLS, "GAS, PETROL AND OIL ENGINES" (LONGMANS, GREEN & CO.)

FIG. 14.—DIAGRAM OF EARLY "MAYBACH" CARBURETTER

brated device is given in fig. 14. Within the chamber A is a light brass or copper cylindrical float B which maintains at a constant level the petrol supplied through C by its action on the central needle valve D through the weighted levers E. A small duct H maintains constant communication between the float chamber and the spray chamber F which contains the spray nozzle J within which the petrol rises nearly to the top when the engine is at rest. During the suction stroke air is drawn through the funnel-shaped intake OO and gauze screen K, and passes up the *Vena contracta* or choke tube L surrounding the spray nozzle; in the choke tube the air velocity is great and its pressure in consequence small; the petrol accordingly issues from the nozzle in a very fine stream and, mingling with the air, is broken up into spray. This "atomization" and the subsequent vapourizing are assisted by impact upon a corrugated cone M, above the jet; the mixture then passes on to the engine along an inlet pipe N, being usually adjusted on its way by admission of a regulated further quantity of fresh air. It is clear that by use of the spray nozzle all the fuel is used, and no selection of the more volatile constituents is possible.

The specific gravity of commercial "petrols" has risen steadily from .68 to .78, the usual range being however from about .72 to .76. Increasingly large supplies are obtained by the "cracking" of heavier petroleum oils. (See PETROLEUM; LOW TEMPERATURE CARBONIZATION; GASOLINE; ALCOHOL: *In Industry*.)

Two essentials of a motor spirit for every-day use are:—(1) Easy starting, and (2) "Anti-knock" properties. Some heavier petrols do not vapourize at (British) winter temperatures and recourse must be had to carburetter warming to enable a start from cold to be effected. The possession of "anti-knocking" properties is of the greatest value in the fuel; detonation is an almost instantaneous automatic explosion of the mixture as a whole, and is evidenced by the "pinking" or "knocking" of the engine; it causes an immediate reduction in power and rapid overheating which sets up pre-ignition of the mixture. Moreover an easily detonating fuel restricts the compression ratio that may be used in the engine, and so reduces its thermal efficiency. (See p. 500 under GAS ENGINES.)

Certain substances, as the liquid hydrocarbon toluene (C_7H_8), the coal tar product benzol, ethyl alcohol, lead tetra-ethyl, etc., when added to ordinary "petrols" in suitable proportions possess the property of reducing the tendency of the fuel to detonate, and are accordingly often termed "anti-knock dopes." Modern petrols are carefully prepared mixtures designed to possess reasonable anti-knock and easy-starting qualities. Exhaustive investigations relating to the various liquid fuels for motors were carried out by the Empire Motor Fuels Committee, whose Report 1923-4 is of great value.

RATING AND PERFORMANCE

It is shown above that the brake horse power of a single-acting four-stroke petrol engine with N cylinders is expressed by:—

$$\text{B.H.P.} = 992 \cdot d^2 \cdot \eta_p \cdot s n N \times 10^{-9}. \quad (1)$$

For rating purposes in car and motor-boat competitions it was found necessary at an early date to have some formula which should give simply, and in terms of some easily ascertainable dimensions of the engine, the maximum practicable horse-power, to a reasonable degree of approximation.

An examination by Sir D. Clerk, of the performance of about 100 engines in 1905-6 showed at that time a prevailing piston

speed $\left(= \frac{n \times 2s}{12} \right)$ of roundly 1000 feet per minute, with a brake

mean effective pressure, η_p , averaging 70 lb./sq.in. If, in (1) above, 6000 be substituted for $s n$ and 70 for η_p , the equation will be found to reduce by common arithmetic to:—

$$\text{B.H.P.} = 0.417 d^2 N \quad (2)$$

In 1906, the Royal Automobile Club decided to take 0.4 as the coefficient instead of 0.417, and thus was obtained the famous R.A.C. Rating Rule for petrol engines, viz.:—

$$\text{R.A.C. Rating} = 0.4 d^2 N \quad (3)$$

where d is the cylinder bore in inches. This simple formula was also adopted by the British Treasury for taxing purposes, and has continued in operation up to the present time.

In passing, it may be noted here that at the end of 1927 there were running on the 178,361 miles of roads in Great Britain, a total of 1,694,000 licensed motors, as compared with 270,000 in 1919. The amount received by the British Treasury for motor licences for the year ending Nov. 30, 1927, totalled £23,456,378.

The R.A.C. and Treasury rating formula, depending only upon the number and the *square* of the bore of the cylinders, immediately caused petrol engine designers to concentrate on the problem of obtaining a maximum output from the minimum cylinder.

In this direction extraordinary success has been achieved, particularly by British designers; even by 1912 tests of normal engines at Brooklands showed a power output averaging nearly 50% greater than that given by the R.A.C. formula, individual cases showing an excess of even 100%. Much of the improvement has resulted from recognition of the necessity of designing an engine not only as a prime mover, but also as a highly efficient *pump*; the increased pumping, *i.e.*, volumetric efficiency, coupled with increased revolution speeds, has enabled remarkable results to be achieved; a notable early instance is furnished by a Vauxhall four-cylinder 3.54 in. \times 5.12 in. racing engine, with a Treasury rating of, roundly, 20 H.P., which developed 90 B.H.P.—or $4\frac{1}{2}$ times its rating—when running at 3,600 rev. per min.

After the outbreak of war in 1914 it soon became manifest

that the high-speed petrol engine was of fundamental importance in connection with road transport, aircraft, and later “tanks,” and all available engineering skill was for some years again concentrated upon effecting still further improvements. There have resulted very high-speed motors, both small and large, of extraordinarily high power output in relation to their size and weight, rivalling in efficiency the largest slow-running stationary types. Many examples can be cited from the tiny four-cylinder, seven H.P. and eight H.P. Austin and Singer designs respectively to the six-cylinder 35/120 horse-power Daimler engine, the lower figure representing the R.A.C. rating.

Even more striking is the astonishing success achieved with the petrol engine as applied to racing aircraft; thus the 1928 12-cylindred “broad-arrow” water-cooled four-stroke single-acting Napier “lion” racing aero-engine with a bore of 5.5 in. and stroke of 5.125 in., using a compression ratio of 10:1, and a fuel composed of 75% petrol, 25% benzol, and a small “dope” of lead tetra-ethyl, and weighing 835 lb., had a power output of 875 B.H.P. at 3,300 rev. per minute; or 1 B.H.P. for each 0.954 lb. of weight. (See AERO-ENGINE.)

In Table III. some figures are given for a few typical modern engines; the values in the extreme right-hand column depend on the nature of the service demanded from the engine; thus petrol engines for marine work, or for driving heavy road lorries are called upon for a much heavier continuous power output than are the engines of normal motor-cars, and are accordingly more robustly built and are in general run at somewhat slower speeds. At the extreme top of the range of output performance is the racing aero-engine from which all that is demanded is an absolutely maximum output during a very short period of time.

Capacity Rating.—A mode of petrol engine rating much employed for classifying purposes is that obtained by taking the total volume swept out by the pistons in one stroke of the engine, and this is termed the “capacity” rating. It is evidently expressed by piston area \times stroke \times number of cylinders, or, in symbols:—

$$\text{Capacity Rating} = 0.7854 d^2 s N \quad (4)$$

If d and s be in inches, the value is expressed in cu.in. It is, however, more usually expressed in cubic centimetres; so that d and s , denoting the bore and stroke in *millimetres*, and N being the number of single-acting four-stroke cylinders, we have:—

$$\text{Capacity Rating} = 7854 d^2 s N \times 10^{-7} \text{ c.c.} \quad (5)$$

$$\text{or, in litres,} \quad = 7854 d^2 s N \times 10^{-10} \quad (6)$$

A useful expression of performance is to state the B.H.P. per litre of capacity; this is given in the extreme right-hand column of Table III., and is of course at once obtained by dividing the B.H.P. by the capacity. If the general formulae for B.H.P. (Eq. 1) and for capacity (Eq. 4) be employed we get the useful relation:—

$$\text{B.H.P. per litre} = 771 \cdot \eta_p \cdot n \times 10^{-7} \quad (7)$$

TABLE III.—Some data relating to a few typical engines of recent years

Engine	No. of cyl.	Bore		Stroke		Rating		Normal full speed r.p.m.	B.H.P. at normal full speed	B.H.P. per litre of capacity at normal full speed
		Inches	mm.	Ins.	mm.	R.A.C.	Capacity in c.c.			
Thornycroft 4-ton lorry engine, M/4	4	4.5	114.3	6	152.4	32.4	6,245	1,200	37	5.92
14/28 Morris-Oxford normal motor-car engine	4	2.95	75	4.02	102	13.93	1,802	1,700	24.3	13.5
35/120 Daimler sleeve-valve large car engine	6	3.85	97	5.13	130	35.5	5,764	1,600 (at a car-speed of 45 m.p.h.)	76	13.2
7 H.P. Austin; the very-small-car-type engine	4	2.2	56	3.0	76	7.74	748	2,400	10.5	14.0
8 H.P. Singer; a small four-seater car-type engine	4	2.2	56	3.38	86	7.74	848	2,000	12.4	14.6
Napier “Lion” racing aero-engine	12	5.5	139.7	5.125	130	145.2	23,907	3,300	875	36.6
Bristol Mercury Mk I. racing aero-engine	9	5.75	146	6.5	165	119	24,854	2,500	800	32.2

wherein ηp is the brake mean efficient pressure in lb./sq.in. and n is the number of revolutions per minute.

Small Motor-car Engines.—A recent 15.9 Morris engine, a typical engine of the average motor car, is a four-cylindere, four-stroke vertical unit of 3.15" (80 mm.) bore, and 4.92" (125 mm.) stroke, and accordingly has a Treasury rating of $0.4 \times 3.15^2 \times 4 = 15.9$, and a capacity of $7854 \times 80^2 \times 125 \times 4 \times 10^{-10} = 2.513$ litres.

The four cylinders are cast *en bloc* with side-by-side inlet and exhaust valves cam-driven through adjustable tappet rods; the valves are all of the same size, and their springs and stems are enclosed by a readily removable cover-plate to exclude dust and retain oil. The cylinder heads are detachable, facilitating greatly decarbonisation and access to the valves.

The power output by bench tests is as follows:—

At rev. per min.	1,000	1,500	2,000	2,500
B.H.P.	14.0	21.5	27.5	31.2

The off-set hollow crankshaft is borne in three bearings which are housed in the lower part of the cylinder block, thus giving great rigidity to the engine. The connecting rods are of duralumin, and all main and big-end bearings are of white metal in bronze shells. Aluminium-alloy pistons are used. Lubrication is forced, by a drowned plunger pump driven by an eccentric on the camshaft,—to the three main crankshaft bearings, the four big ends (via the hollow crankshaft), and also to the camshaft bearings. The pump in-take is through a gauze filter easily removable for cleaning; a gauge on the dashboard of the car indicates the oil pressure in the circulating system while running. Ignition is by the usual H.T. (high-tension) magneto.

The "Baby Austin" Engine.—The performance of the modern tiny motors typified by recent Austin and Singer designs is so remarkable as to merit special notice. A section of a seven H.P. Austin small-car engine is given in fig. 15. The four *en bloc* cylinders of 2.2 in. bore and 3.0 in. stroke (see table) are fitted

FIG. 15.—SECTION OF 7 H.P. AUSTIN ENGINE

with a detachable head. The pistons are of aluminium alloy. The side-by-side valves are cam-operated in the usual manner. Lubrication is by a drowned oil-pump driven from the camshaft as indicated, and ignition is by H.T. magneto. Thermosyphon cooling with a "film" radiator and fan. The four-throw crankshaft is borne in two roller bearings. The mixture is supplied by a Zenith carburetter. The power output is:—

At rev. per min.	1,000	1,500	2,000	2,500	2,800
B.H.P.	3.8	6.2	8.7	11.0	12.0 (max.)

This miniature engine propels its car containing three or four adults with ease at 35 miles per hour on an ordinary good road-surface, with a petrol consumption of 40–50 miles per gallon.

The Eight H.P. Singer "Junior."—A recent design of this car has an engine of the same bore as the seven H.P. Austin, but with the larger stroke of 3.38 in. (see table). The cylinders and crankcase form a single casting and an aluminium casing houses

FIG. 16.—THE 35/120 H.P. 6-CYLINDER DAIMLER SLEEVE-VALVE ENGINE

the timing gear and forms the front support of the engine. The short stiff crankshaft is borne in two solid white-metalled bearings. The pistons are of cast iron with three spring rings, the lowest ring securing the gudgeon pin. The connecting-rod big end bearings are of white metal in bronze shells. The valves in this engine are overhead and inclined and are operated by rockers; the overhead camshaft, oil-pump, magneto, and starting and lighting dynamo are all driven from an intermediate shaft placed above the front end of the crankshaft and driven by it through helical gearing; the drive from the intermediate shaft to the overhead camshaft is by double roller chain fitted with an automatic tensioning device. The detachable cylinder head is a single casting carrying the camshaft in three bearings, and is fitted with renewable valve guides. Lubrication is by pump and troughs; the pump intake draws the oil through an easily removable gauze filter, and delivers into four troughs into which the connecting rods dip, and also up to the overhead camshaft and valve rocker bearings. The oil pressure is indicated by a gauge on the dashboard. Cooling is on the "convection" or "thermo-syphon" system. Ignition is by H.T. magneto. A Solex horizontal carburetter is used. The engine is enclosed, dust-excluding and oil-retaining. The power output is:—

At rev. per min.	1,000	1,500	2,000	2,500	3,000	3,250
B.H.P.	6.2	9.3	12.4	14.9	16.2	16.4 (max.)

and in the autumn of 1927 a car fitted with one of these very small engines accomplished a run from London to Edinburgh, and back in $24\frac{1}{2}$ consecutive hours, corresponding to an average speed throughout of about 33 miles per hour.

Sleeve Valve Engines.—In these the poppet valves are replaced by ported sliding sleeves which, in the single-sleeved engine is the working barrel of the cylinder and has a motion partly reciprocating and partly angular, while in the double-sleeved engine both the ported working barrel and the second ported sleeve enveloping it have a simple axial reciprocating motion.

Space permits but a brief reference to the single-sleeved type, but the Burt-McCollum design has been successfully employed for some years in the engines of Barr and Stroud, Caledon, Argyll, and Karrier; an exhaustive account of this type is given by Ensor in the *Proc. Inst. Auto. Engrs.* (1927–8).

The Daimler-Knight Double-sleeve Engine.—Used with great success since 1908, the smooth running "Silent Knight" engine is deservedly famous. The four-stroke, single-acting, six-cylindere, 35/120 h.p. design, illustrated in fig. 16, has a bore of 3.85 in. a stroke of 5.13 in., and consequently a Treasury rating of 35.5. Bench tests show that at a speed of 3,000 rev. per min. the engine develops roundly 120 b.h.p. At a car speed of 60 miles per hour the engine runs at 2,140 rev. per minute. The manner in which

the ported light steel sleeves regulate the inlet and exhaust periods is clearly shown in fig. 17.

The inlet port opening and the exhaust port closing at the beginning of the suction stroke is shown in A. The inner sleeve is rising and the outer sleeve is descending. The exhaust is shown closed and the inlet closing at the beginning of the compression stroke in B. The ports in the inner sleeve are passing

FIG. 17.—DIAGRAM SHOWING ACTION OF THE DAIMLER SLEEVE VALVES

up into the cylinder head, where they are sealed by the junk ring during the period of maximum pressure and temperature at the beginning of the firing stroke (C). In D, the exhaust is already well opened at the beginning of the exhaust stroke. The sleeves are now again moving to the position shown in A.

SPECIAL TYPES OF INTERNAL COMBUSTION ENGINES

The Humphrey Internal Combustion Pump.—If the water within a partially filled, vertically placed U-tube be displaced it will perform nearly isochronous oscillations about its position of rest. H. A. Humphrey (1906-9) has ingeniously utilized the oscillatory motion of a large water-column to effect the raising of great volumes of water from a lower to a higher level.

A diagrammatic view of the simplest form of the Humphrey

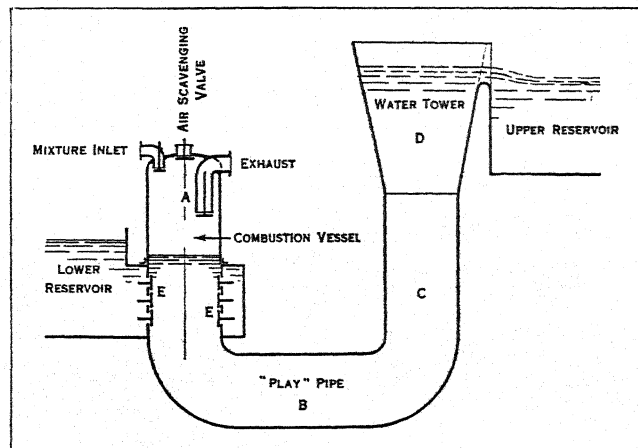

FIG. 18.—DIAGRAM OF THE HUMPHREY INTERNAL COMBUSTION PUMP

pump is given in fig. 18. ABCD is the U-tube the arm A being closed and forming the combustion vessel, while the splayed-out arm D is open and in free communication with the upper reservoir. Through the mixture inlet an explosive charge of gas and air is introduced into A and electrically fired; the pressure developed by the explosion drives down the water level in A, correspondingly raising it in D, thus producing delivery into the upper reservoir. The great momentum of the moving water column causes the downward motion in A to continue until the pressure in the com-

bustion vessel becomes less than atmospheric; the exhaust valve then opens by its own weight and at the same time the air scavenging valve is opened by the atmospheric pressure; the burnt gases are now discharged into the atmosphere. By this time the level in A has fallen below that in the lower reservoir and a new supply of water then enters through the nest of valves EE; during the whole of this period water is evidently being delivered into the upper reservoir. The column then comes momentarily to rest, and during the return swing to the left the rising level in A first closes the exhaust valve by its impact and next compresses above it a mixture of residual exhaust and scavenge air; when the column is thus again brought to rest the pressure in the upper part of A being considerable, the column begins its second swing to the right and in the course of this the pressure again falls to less than that of the atmosphere but this time, by means of a suitable interlocking gear, the exhaust and air scavenging valves are held closed; the mixture inlet valve, however, opens and an explosive charge of gas and air enters A. The second swing of the column to the left then compresses this fresh charge in A, and the cycle is then repeated. The Humphrey pump thus works on a modified four-stroke cycle (see above, "Gas Engines"), but with strokes of unequal length, the working (expansion) stroke being particularly long, which makes for its high efficiency. The cycle-frequency depends upon the mass of water in the "play" pipe, and is determined by varying the length of this pipe; a frequency of 15 to 30 cycles per minute is commonly employed. The pump is very quiet, as the exhaust takes place at practically atmospheric pressure, and is suitable for lifts up to 150 feet. The pump is also built to work on a two-stroke cycle; and later designs provide for the use of oil as fuel.

At the Metropolitan Water Board's 300 horse-power installation at Chingford, Essex, England, are four pumps each with a cylinder A seven feet in diameter, and each designed to lift 40 million gallons per diem; and a fifth, with a five-foot cylinder dealing with 20 millions per diem. These are all operated by producer gas supplied by four Dowson gas producers using anthracite as fuel. The consumption per actual pump-horse-power hour is only about 0.9 lb. of anthracite.

The Still Internal Combustion Steam Engine.—Commonly some 30% of the total heat of the fuel used in a Diesel engine is carried away in the exhaust gases at a (full load) tem-

FIG. 19.—THE STILL INTERNAL COMBUSTION STEAM ENGINE

perature of some 800-900° F. and, in favourable circumstances, a saving in running costs can be effected by utilizing this heat in special types of steam boiler. W. J. Still has gone further by arranging for the exhaust and jacket heat to add directly to the power output of single-acting Diesel engines; this he has effected by enclosing the lower portion of the working cylinder, and arranging for this end to work as an ordinary high-pressure condensing steam engine.

The method adopted is illustrated by fig. 19. Above the piston the usual Diesel sequence of operation is performed. The upper (Diesel) part of the cylinder is heavily water-jacketed, and the lower part is steam-jacketed; in the steam-jacket works a slide-

valve by which admission of steam to the lower end of the cylinder is regulated: the exhaust steam from the cylinder passes into an ordinary condenser. The water-jacket is connected at its top with the upper part of an auxiliary oil-fired steam boiler (shown on right), and at its lower end, through a feed-heater, with the bottom of the same boiler. Through this feed-heater passes the exhaust from the Diesel end of the working cylinder, entering at a temper-

FIG. 20.—THE "SWASH-PLATE"

ature of, say, 900° F and leaving at the much reduced temperature of some 150° F only, thus giving up heat to the water system. This heated feed-water then enters the cylinder jacket, and receives some further heat by conduction through the working barrel, thereby rising in temperature to, say 350° F. The water (and steam) circulation continues through the upper pipe to the auxiliary steam boiler, in which a pressure of 180 lb./sq.in. is shown.

From the top of the boiler dome is taken the dry working steam to the steam jacket and thence, via the slide valve, to the lower end of the working cylinder. In this way heat conducted through the upper part of the cylinder liner (or "working barrel"), together with much of the heat ordinarily wasted in the exhausted burnt gases is recovered and utilized, and at full load it is claimed that up to 7 lb. of steam may be obtained per B.H.P. hour of the engine, with an increase of about 20% in power output, and much improved economy in fuel consumption. The cylinder liner in the Still engine is usually only about one-third of the normal thickness, and is ribbed externally to improve its heat-conducting properties.

Trials by C. B. Boys showed that, per B.H.P. hour, 3.28 lb. of steam was obtained from the jacket alone, and 6.0 lb. from the jacket and exhaust gases jointly; also that the mean effective pressure from the Diesel end of the cylinder was 90 lb./sq.in., while that from the steam end was 14 lb./sq.in., twice per cycle; accordingly this four-stroke engine showed a total mean effective pressure per cycle of $90 + 2 \times 14 = 118$ lb./sq.in.

A four-cylinder Scott-Still engine, 22 in. diameter \times 36 in. stroke, giving 1,250 B.H.P. at 120 rev. per minute using solid (or "airless") injection with automatic fuel inlet valves (see DIESEL ENGINE), tested by the Marine Oil Engine Trials committee, showed a fuel consumption of only 0.354 lb. per B.H.P. hour at full load, corresponding to an indicated thermal efficiency of 40.9%, and a brake thermal efficiency of 36.9%. In this engine the steam side was arranged to operate on the compound principle, one high-pressure cylinder exhausting into a receiver whence the remaining three cylinders derived their steam supply. Scott-Still engines are also often arranged with some cylinders as ordinary single-acting Diesels and the rest as combined Diesel-steam units as above described.

In the 1928 Scott-Still marine Diesel engine the general method of waste-heat recovery was unchanged but the steam cylinders were separate double-acting cylinders of normal type. The 3,000 B.H.P. Scott-Still engine of 1928 design, for example, comprised six single-acting two-stroke solid injection Diesel cylinders of 27 in. bore and 45 in. stroke, working in conjunction with two double-acting steam cylinders of 25 in. bore and 45 in. stroke at a normal speed of 105 rev. per minute.

The Still engine involves the addition of a feed heater, an auxiliary boiler, a condenser, and all the associated steam engine mechanism to the ordinary Diesel engine; but it enjoys, among others, the following valuable compensating advantages:—(1) An extremely high fuel economy. (2) By firing-up the auxiliary boiler

the total mean effective pressure can be substantially increased thus enabling the engine safely to carry a big overload. (3) Steam from the auxiliary boiler serves for starting the engine, and the cylinders are well heated when the Diesel parts come into operation; the use of compressed air for starting is thus avoided. (4) Manoeuvring is also simplified, and again the use of compressed air is rendered unnecessary.

The Michell Crankless Engine.—This engine was rendered possible by the invention of A. G. M. Michell in 1905 of the famous "Michell thrust block," in which the theoretical conditions laid down by the late O. Reynolds were first definitely incorporated. Prior to the introduction of the Michell bearing, multiple collared bearings were invariably used, in which experience showed that the maximum thrust pressure practicable was about 60 lb./sq.in. Michell soon showed that 500 lb./sq.in. at 1,750 rev. per minute could be maintained continuously, with a bearing temperature not rising above 125° F; later, improved bearings were constructed which functioned continuously under a thrust pressure of 3,000 lb./sq.in.; and under special test conditions as much as 13,000 lb./sq.in. has been successfully borne.

Briefly, in the Michell bearing the rubbing surfaces are capable of tilting, thus becoming slightly inclined to one another in the direction of motion, so that the oil film between them is wedge-shaped with the thicker edge at the entrance. A continuous flow of oil between the surfaces is thus induced and the film constantly renewed, thus effectively preventing actual metallic contact from occurring. In these circumstances the coefficient of friction is reduced to about .0018, i.e., only some $\frac{1}{20}$ of the value when the rubbing surfaces are maintained strictly parallel to each other.

A plane disc fixed obliquely on a rotating shaft is an old mechanical device for obtaining reciprocating motion, and was illustrated and described as long ago as 1841 by Willis in his classic *Principles of Mechanism* wherein also it is shown that if the shaft rotates uniformly a simple harmonic motion of the reciprocating piece results. The device is illustrated in fig. 20; AA is the "swash-plate" or "slant," mounted obliquely upon a shaft BB, and CC is a rod whose end is kept always in contact with the plate as indicated. Obviously, if the shaft BB rotates on its axis the rod CC will reciprocate. Conversely, if CC reciprocate,—and friction is not too great—it will communicate to BB an angular motion through a semicircle in making its stroke from right to left; by a second rod similar to CC, placed to the left of the swash-plate the shaft can be caused to perform a second semicircle, thus completing a revolution. This is the *modus operandi* of the swash-plate engine; CC becomes the piston and piston rod, the spring E the working impulse, and the bearing F the engine cylinder. Hydraulically-operated multi-cylindrical swash-plate engines have been used for years in warships for training the big

BY COURTESY OF THE NATIONAL GAS ENGINE CO.

FIG. 21.—NATIONAL-MICHELL CRANKLESS ENGINE

guns; these engines are both of single- and double-swash-plate design, the latter having two swash plates set back to back, conferring valuable balancing qualities.

The nature and action of the Michell crankless gas engine will now be clear from inspection of the diagram fig. 21, showing a "slant" with eight cylinders, arranged in opposed pairs spaced equally around, with their axes all parallel to that of the shaft. The working pressure is communicated to the "slant" through Michell thrust slippers having spherical seats, as indicated. As the engine operates on the four-stroke cycle (see above "Gas En-

gines"), opposed pistons are coupled together by means of a yoke in order to effect the suction strokes.

Eight 280 horse-power National-Michell crankless engines, each direct-coupled to a Michell gas booster, were installed at the works of the Australian Gas Light Co. of Sydney, N.S.W. Each unit delivers 500,000 cu.ft. of gas per hour at a pressure of 7.25 lb./sq.in., when running at its normal speed of 750 rev. per minute. (G. A. Bt.)

INTERNATIONAL, THE. A number of international associations or congresses of Labour and Socialist bodies have at various times adopted the title of the "International," and three of them are of historic importance. The first of these, having for its full title the International Working Men's Association, was established in 1864, and came to an end ten years later after a troubled existence. This was commonly known as "The International," and is thus termed historically. Founded under the leadership of Karl Marx and Engels—Marx himself drew up its programme in 1866—it was in some of its elements a revolutionary body and as such is revered by the Communists of the 20th century.

The Second (Socialist) International, was founded 15 years after the demise of the International, and constituted, down to the outbreak of the World War, a body representative of the world's Labour-Socialists. The war brought irreconcilable differences and consequent secessions, and the establishment of a Bolshevik Government in Russia led to the formation in 1919 of the Third (Communist) International, also known as the Komintern, which now leads the world's revolutionary forces, the Second (Socialist) International adhering to moderate views and the parliamentary principle. The Second and Third Internationals thus exist (1928) contemporaneously. In the following sections, the history of these three bodies is described in some detail.

THE (FIRST) INTERNATIONAL

The International Working Men's Association, commonly called "The International," was formed in London in 1864. It was a society of working men of all nations, somewhat like a cosmopolitan trades union, but bearing a still closer resemblance to an international social science association for discussing and furthering the rights of labour. The occasion of its formation is commonly alleged to be the visit of some French workmen to the London Exhibition of 1862. In the course of their visit the labour question was discussed, and a desire for the further interchange of ideas expressed. Nothing decisive was done till 1864, when a great public meeting of working men of all nations was held at St. Martin's hall, London, and a provisional committee was appointed to draft the constitution of the new association.

The first four congresses of the International, held at Geneva (September 1866), Lausanne (1867), Brussels (1868) and Basle (1869), marked the rapid development of the association. It gained its first triumph in the effectual support of the bronze-workers at Paris during their lock-out in 1867; and it repeatedly aided the English trade unionists by preventing the importation of blackleg labour from the Continent. It soon spread as far east as Poland and Hungary, and it had affiliated societies with journals devoted to its cause in every country of western Europe.

Anarchism v. Socialism.—It was supposed to be concerned in all the revolutionary movements and agitations of Europe, gaining notoriety as the rallying point of social overthrow and ruin. Its prestige, however, was always based more on the vast possibilities of the cause it represented than on its actual power. Its organization was loose, its financial resources insignificant; the Continental unionists joined it more in the hope of borrowing than of contributing support. At the successive congresses its Socialist tendencies became more and more pronounced; it declared its opposition to private property not only in railways but in mines and the soil, holding that these should revert to the community. The principle of inheritance was saved only by a narrow majority. In 1869 M. Bakunin, the Russian anarchist, with his immediate followers, joined the association, and at once asserted his character as the "apostle of universal destruction."

The relation of the association to the Commune rising at

Paris in the spring of 1871 has been the subject of much dispute. It is now agreed that the International as such had no part in originating it, but its French members joined in it heartily. After the fall of the Commune the general council of London, Karl Marx included, issued a long and trenchant manifesto, approving its action and extolling the "glorious vanquished." From the fall of the Commune the decline of the association is to be dated. The English trade unionists, intent on more practical concerns at home, never took a deep interest in its proceedings; the German Socialists were hindered by law from corporate action; America was too remote. But it found its worst enemies within its own ranks; there was a deep division between the Socialists led by Marx and the anarchists led by Bakunin and the Swiss Federation of the Jura at the congress of 1872, held at The Hague, when Bakunin, being expelled by the Marx party, formed a rival International, which found its chief support in Spain and Italy. The old International now transferred the seat of its general council to New York; but it survived only long enough to hold two more congresses (Geneva 1874, Philadelphia 1876) and then quietly expired.

The party of Bakunin, styling themselves "autonomists," had a bloodier history. The programme of this party concentrated on the violent destruction of the State, passing over subsequent difficulties. It endeavoured to realize this in the great communal risings in southern Spain in 1873, when its adherents took part in the general insurrection, and at Alcoy, San Lucar de Barrameda and elsewhere were for a short while in power. They failed in leadership and organization, and were suppressed, though not without difficulty, by the national troops. The "autonomists" lingered on till 1879, when the collapse was complete of an association which once extended from Hungary to San Francisco, and alarmed the minds of men with visions of universal ruin. (X.)

THE SECOND (SOCIALIST) INTERNATIONAL

The Second International was constituted in 1889, 15 years after the disappearance of the First. Unlike the latter, it possessed no powerful central authority and its early meetings were mainly devoted to discussion of the tactics and methods of the affiliated national parties, but from 1911 onward the question of war and peace received more attention. It had already been discussed at the congress of Amsterdam in 1903, and from that date Jaurès began the study of the question which inspired his book, *L'Armée nouvelle*. At the congress of Stuttgart in 1903 the question was again discussed, at greater length, and Hervé's denunciation of all "patriotism" led Bebel and Volmar to declare that the Social Democrats would instantly rise to defend Germany if ever she were attacked.

Conditions Before the War.—The European horizon steadily darkened, especially after 1911. The Agadir incident, the Italo-Turkish War and the Balkan wars, in succession, made the menace of a general conflagration appear imminent, and the efforts of the Socialist parties to avert the catastrophe became more urgent and strenuous from that time. Their efforts culminated in the extraordinary congress (1912) at Basle, called to consider the international situation and the action to be taken by Social Democrats to prevent war. A manifesto was issued, exhorting all workers to unite to secure from their Governments a pacific foreign policy.

This problem of peace was put on the agenda for the tenth congress of the International which was to have been held in Vienna two years later, in Aug. 1914. The congress would have coincided with the 50th anniversary of the founding of the International in London in 1864. For this occasion Austrian Socialists had prepared an illustrated commemorative album in which Kautsky, Victor Adler and others had related the history of the Socialist movement during the last half century. This document, which appeared in print at the moment when the World War broke out, was distributed ten years after as a souvenir among members of the executive committee of the International when they met in the former capital of the Habsburgs in June 1924. The album contains, among other things, a series of medallion portraits of 66 members of the B.S.I. (International Socialist Bureau), which had its headquarters before the war in the Maison du Peuple at Brus-

sels. Lenin's portrait is not among them, although he was a member of the bureau for many years; but there are Rosa Luxemburg and C. G. Rakovsky, together with Jaurès, Ebert (the future president), also Stauning, Branting and MacDonald, who later became premiers of Denmark, Sweden and Great Britain respectively. There are delegates of trade unions too, but these are few and far between. The bureau, representing all the live forces of Socialism, met for the last time at the Maison du Peuple, Brussels, on July 29 and 30, 1914.

Even at that moment, when the world already lay under the shadow of war, optimism still prevailed. Adler regarded a war between Germany and France as a moral impossibility; Haase, chairman of the Social Democratic group in the *reichstag*, relied at this eleventh hour, not on humanity, but on the pusillanimity of the kaiser. Jaurès, speaking on the evening of July 30 for the last time, still affirmed his confidence in a pacific solution, but prophesied in a flash of inspiration that if, in spite of all, war were let loose on the world by its masters, then at the close, each nation would turn upon those responsible for the disasters of the war and say: "Go, and seek pardon from God and man." The next day he was assassinated in Paris, and a state of war had been declared in Germany.

The bursting of the storm put an abrupt end to all international activities (see SOCIALISM). While the war lasted no single meeting of the executive committee took place, but some tentative efforts were made to revive international action. The most important of these were an attempt by the Dutch-Scandinavian committee (vigorously supported by Camille Huysmans, secretary of the Second International) to convene an international congress at Stockholm in 1917, and that of the Italian Socialist Morgari to convoke conferences at Zimmerwald (Sept. 1915) and at Kienthal (April 1916). The first of these efforts (the projected Stockholm conference) proved abortive mainly because of the refusal of the Allied Powers to grant passports to the delegates; at the Zimmerwald and Kienthal conferences only certain groups of the international proletariat were represented, and from these elements there was presently to emerge the Communist International known as the Third International.

Activity After the Armistice.—On the morrow of the Armistice the need for international unification was felt with renewed force. Conferences were summoned successively at Berne (Feb. 1919), Lucerne (Aug. 1919) and Geneva (Aug. 1920) with a view to re-establishing the Second International. Meanwhile, however, the so-called Third or Communist International had been formed at Moscow, and for some time parties or groups who were unwilling to be affiliated to either the Second or the Third grouped themselves in a Workers' International Union of the Socialist parties with Vienna as its centre—hence the name "Vienna International." (The principal groups concerned were the British I.L.P., the German Independent Socialists and the Austrian Social Democrats.) In the beginning of 1920 this organization tried to bring about the unification of all proletarian organizations, and succeeded in calling together in Berlin a reunion of the executives of the three groups in April 1922. But this effort at reconciliation ended in complete failure.

Since then the Communist International has steadily accentuated its opposition to Social Democracy. On the other hand the points of dispute between Vienna and London became progressively less. In 1921-22 the French, English, German, Italian and Belgian Socialists, who were adherents either of the Vienna International or the Second International, met first in Paris, then in Frankfurt, and of one accord adopted the resolutions which have since become famous as the "Frankfurt Resolutions." Anticipating the Dawes scheme, these demanded the reduction of the German debt to a reasonable figure, and, further, demanded the end of military occupations of former enemy territory and the annulment of inter-Allied debts.

Congress at Hamburg.—By December of the same year these two internationals had agreed to call a Socialist international congress at Hamburg. This took place on May 27, 1923, when the International was reconstituted—the Communists being excluded—and the conditions on which parties or groups could be ad-

mitted were defined. Agreement was reached with difficulty on a Franco-German text which, drawing on the Marxian vocabulary for its somewhat heavy terminology, appealed to "those who acknowledged the aim of the working class to be the replacement of the capitalist mode of production by the Socialist mode of production and who see in the *class struggle* (*lutte des classes*) which manifests itself in political and economic action the means of emancipating the working class."

But when it came to translating this text into English the British delegates raised a discussion, arguing that the words "*lutte des classes*"—the touchstone of Socialism on the Continent—were not in current use in England; that the extremists, who alone used the expression, spoke not of "class struggle" but of "class war," and that it would be better in these conditions to retain the idea but to paraphrase it in such a way as this: "independent political and industrial action of the workers' organizations." And so it was arranged. The Franco-German text was retained, for it could only have been altered at the cost of emasculation; but for British consumption a free translation was allowed.

The present writer has thought it necessary to report this little incident, as it cannot fail to be instructive, showing as it does that, in spite of community of words and, on the whole, unity of tactics, English Labour men and Continental Socialists do not speak quite the same language. Now, these differences of terminology are the outward expression of other more deep-rooted differences arising out of the widely differing environment in which contemporary Socialism is formed and developed. On reading such pre-war books, for instance, as the *Études socialistes* of Jean Jaurès, Ramsay MacDonald's *Socialism and Society* or Kautsky's *Das Erfurter Program*, we see how widely the Socialism of Jaurès, instinct with the spirit of the French Revolution, and still more the Socialism of Ramsay MacDonald, who draws inspiration from the pacific and fraternal idealism of Christianity, is to be differentiated from the more "materialist" and more "economic" Socialism of the German Marxians.

Since the war, however, these differences have become less acute, even from the theoretical point of view. A sort of amalgam has been established between the various national parties. German Socialism has become less doctrinaire; French Socialism has drawn nearer to Marxianism under Guesdist influence; the Socialism of the I.L.P. has almost completely captured the English working-class movement. Between those parties which recognise Social Democracy as their basis, there exists not only international unity of organization but unity of programme.

This emerges clearly from the two first congresses of the new International. The Hamburg congress of 1923 succeeded beyond all expectations. There were present 630 delegates from 30 countries, representing 7,000,000 affiliated members. During the debates, which lasted five days, the following points were discussed: international action against international reaction, working-class policy on an imperialist peace, the eight-hour day, and the reform of international social legislation. But the most important achievement of the congress was the fusion of the London and Vienna groups and the adoption of the statutes of the new "Labour and Socialist International" (L.S.I.).

In the three years preceding the second congress of the new Second International (Aug. 1925) that organization was finally consolidated, and began to make itself more and more felt in international politics; its congresses have been held regularly at the prescribed intervals. There is no gainsaying the fact that direct action by the workers and the existence in all Western countries of a powerful Socialist party (either working within the Government or using its influence from outside) have to a very large extent determined the new policy which eventually produced the London agreement on reparations (1924) and the Locarno pact of mutual guarantee. To be convinced of this we have only to look for a comparison at the resolutions passed at Hamburg on the reparations problem and those at Marseilles on security. There can be no better instance of the influence which Socialism has acquired over the various Governments and of its emergence as the decisive factor in matters of international policy. (For bibliography see the article SOCIALISM.)

(E. VA.)

THE THIRD (COMMUNIST) INTERNATIONAL

The Communist International (abbrev. *Komintern*) is the international organization of the Communist party of all nations, founded in 1919. It is also called the Third International. Its structure and programme it differs from the First and Second. Communism sympathises unreservedly with the first International, founded under the leadership of Marx and Engels, whose policy was essentially one of active revolution. As, however, its organization lacked a definite central point and had not its roots in party associations, its practical manifestation, the Paris Commune, was bound to fail. Lenin evolved his theory of revolutionary movement from the lessons of the failure of the Commune, and arrived at the conclusion that a successful revolution might begin as a spontaneous popular upheaval, but could only achieve and retain victory in the form of an organized and systematically controlled movement which could not only put down all opposition, but could at once organize the resources of the country.

Birth of the Third International.—In 1889, when the Socialist Labour movement had recovered its force, the Second International (*see above*) was founded. Up to 1914 this represented the international organization of the Socialist-Labour movement as a whole. The constructive importance of the Second International, from the point of view of the Communist parties, lay in the fact that it organized and grouped labour in trade unions, co-operatives, educational associations and political parties. The Second International already contained a Bolshevik opposition which refused to assimilate with the larger body. It was led by Lenin, who was a member of the International Bureau (B.S.I.) of the Second International in 1914. In 1914 the Second International collapsed. The Communists date the epoch of the Communist International from this moment. This epoch emerged out of a transitional period comprising the first three years of the war, during which Lenin struggled to "transform the imperialist war into a civil war." The foundations of the Third International were laid at the conferences of Zimmerwald and Kienthal in Switzerland. It only achieved real authority, however, when the leaders of the German army conceived the idea of making the Russian February revolution more extreme. The German supreme command brought Lenin and Trotsky to Russia in the fond hope that the fire of the Russian revolution which they were kindling in Russia would stop at the frontiers of Germany.

The Third International was not formally founded till March 1919. Up to that date the Communist parties believed that they would be able to break up the Socialist parties from within and transform the Second International bodily into a Communist organization in the tempest of the world revolution. Especially during the episodes of the Soviet republics in Bavaria and Hungary, and even after their collapse, during the labour troubles in Britain, Germany, Italy, etc., Moscow continually believed the outbreak of world revolution imminent every hour, and expected that the Socialist parties could be simply absorbed in the Communist parties. As it grew ever plainer that this hope (which at first was shared by Lenin) was Utopian, the Communists devoted even greater energy to their own International.

Fundamental Principles.—The following are their basic principles:

1. The Communist International is the organization of the Communist parties of each nation; it is therefore revolutionary. Its chief purpose is to accelerate the development of events towards world revolution. It rejects any compromise or co-operation with bourgeois parties. Similarly it rejects parliamentarism as a normal method of political development. In certain circumstances it advocates a unity of front with Socialist parties, including the Second International. This is, however, never more than a temporary and tactical co-operation. The Communist International is honest enough to state openly that it is only ready to support the Socialist parties so far as "the hangman's rope supports the convict." The aim of the Communist International is the creation of really revolutionary proletarian parties which shall be the advance guard of the revolution, and the combination of them in a great homogeneous international Communist party. Their headquarters are only "for the moment," as Lenin said, and probably

not for long, in Moscow; later they will move to countries where the economic system and the proletariat alike are more advanced, so soon as one such country achieves a Soviet constitution.

2. The Communist International is no loose organization like the Second International, but an association bound together by a common programme and principles, and receiving its orders from a central organ, the bureau of the Third International. This central organ does not merely issue general rules of conduct, which may be carried out or not by the individual national parties according to their own convictions and views of the general situation; it lays down policy to the smallest details. The men at the head of Communist parties have been repeatedly changed under orders from the International, and tactics (e.g., the question of co-operation with the Socialist parties, or the attitude to be adopted towards parliament) have often been defined in detail by resolutions of the International bureau. This central organ of the Communist International is indubitably in close personal and political touch with the Russian Government, the Soviet of People's Commissaries.

3. The individual Communist parties are, despite a general uniformity, not all organized on the Russian system. The Communist parties of Western Europe are "open parties" which anyone may join. In some countries the Communist parties are proscribed by law. Wherever it is possible, a sort of military organization probably exists, exactly as in the Nationalist and Fascist parties.

4. In matters of internal policy the individual parties are, as already stated, strongly influenced by the Communist International, but there are great differences between the nations. In countries where democracy is firmly based and parliamentary tradition of long standing, the tactics of the Communist parties are correspondingly modified. Communists take part in parliament, bring forward legislative motions, etc.; at times they even co-operate with the Socialist parties. This is, however, only a temporary tactical move, the ultimate aim being always world revolution. The formation of the so-called "unified front" is a means to an end and a tactical move. The organized workmen in the trade unions are to be captured in such a way that the trade unions gradually come under the influence of the Communist parties.

The conditions of affiliation to the Communist International prescribe that every party which desires affiliation to the C.I. must develop a systematic and persistent Communist activity within the trade unions, works committees, co-operative societies and other mass organizations of workmen. Within these organizations it is necessary to organize cells, which by persistent and continuous work must win the unions, etc., to the cause of Communism. The Communist cells must be completely subordinated to the party as a whole.

Developments Outside the Industrial Proletariat.—Since the aim of the Communist International is world revolution, and since the state of the Continent of Europe has grown much less disturbed since 1921, the chief aim of the Communist International proved unattainable. The revolution had taken the offensive at isolated points, but failed to develop into a world-wide movement. The International therefore put forward officially the doctrine that sudden enthusiasm alone will not bring about world revolution; this must be achieved by a strict organization which must first be created. Such an organization, however, presupposes a compact Communist international unified front.

The Communist International began by continuing the traditional policy of the Second International. It desired to be an organization of manual labour. But in Russia the actualities of the situation soon forced the party to admit the peasants as members (at first only the poor peasant, later the medium peasant). A Peasants' International was founded in 1923, but made slow progress. Nevertheless, it then became possible to embrace the extremist agrarian movement—a matter of the greatest importance in countries where large estates are common. The rather unexpected pronouncement was therefore made that "the peasants have become the natural allies of the workmen." Thus a link was forged with what had been the oldest revolutionary movement in Europe. To-day, indeed, with the emergence of the peasants from

serfdom, their status and feelings, especially in central Europe, have changed radically. It is most unlikely that revolutionary feelings will ever become widespread among them.

Oriental and Colonial Propaganda.—Far more important is the connection between the Communist International and parties and currents of thought which may be described as the heart of the movement for national and economic independence among the colonial and semi-colonial territories of Asia and Africa. Countries such as India, China and the wholly independent Japan are already represented in the Communist International by considerable parties, although these parties differ very markedly from those of Western Europe. The psychological bases for intensive Communist propaganda in Asia are, firstly, the appalling conditions in the newly developed enterprises (women's and children's labour, long hours of labour, barrack conditions for workmen); and secondly—perhaps more important—the breakdown of the social structures of these countries. Throughout Asia the family is the basis of society. Industry destroys this, and nothing comes to replace it. But man, in the Far East, cannot live except as member of a community. He cannot grasp the idea of an abstract existence, secured simply by a contract of labour. Existence is uprooted, and all his instincts revolt against an economic system which attempts to make him into an individual. This revolt finds its plainest expression in the Communist movement, the essence of which is thus the resistance of the social instincts to the destructive influences of industrial life.

Furthermore, the restrictions placed by the United States and Australia upon immigration, the restrictions placed on Indian emigration to Africa, the unfortunate results which attended Chinese labour conditions in South Africa, combined with the insistence laid by the white races on the preservation of racial distinctions, have created a real and practical feeling of unity among all coloured races and nations throughout the world—a feeling which extends throughout all Africa and Asia, and as far as the negroes of America. In the face of this racial antagonism, Soviet Russia is the only Power to-day which stands on principle for racial equality and full equality of rights for all races on their own territory.

Thus Communist propaganda directed against the influence of European capitalists and the partisans of racial superiority in Asia has an easy task. Even Japan has been led by similar motives to a political *rapprochement* with Soviet Russia. Communist propaganda in Asia and Africa is therefore adapted to local conditions. Social and national considerations take the first place; less insistence is laid on the purely economic factor.

The resentment against capitalist exploitation, combined with the struggle against the Imperialist European Powers and against the United States, inevitably draws the leaders of those movements towards Russia, and thus towards the Communist International. This connection has been developed by special congresses to the oriental peoples (as that of Baku in 1920), and has certainly been exploited by the Russian Government to further Russia's traditional foreign policy in Asia. In all these countries the small tenant farmers are particularly susceptible to the allurements of the Communist programme.

In the last few years, however, the economic antagonisms have become intensified in the Far East also, especially in China. Chinese industrialists and capitalists have rejected the communistic influence, which has frequently made itself felt by very drastic means, and this class antagonism in the Far East has undoubtedly caused a weakening in the authority of the Third International.

Results up to 1927.—The Communist International forms a bond between the States organized on the Communist system and the Communist parties in the capitalist bourgeois States. In this way one may look on its work as the "formation of the front line of a world-revolution." In fact, a country which contains a strong and active Communist party finds it impossible to participate in a European counter-revolutionary movement. In terms of practical politics, this means that the States of Europe would find it hard to undertake war against Russia, in face of the opposition of their own Communists and Socialists. This is probably the greatest success of the Communist International. The Com-

munist International is therefore both an association of national parties with a definite internal political programme, and at the same time an international political organization of really international importance on a world-wide scale.

It remains to be seen to what extent the fall in Russian credit may result in a loosening of the relations of the European Communist parties with the Russian authorities so that the policy of the Communist parties will no longer depend so much on instructions from Moscow. Hitherto, in spite of the nominal independence of the Communist International, its policy has been clearly dictated from Moscow, whereas in future financial support from Moscow may possibly only take place in exceptional cases.

INTERNATIONAL ADVERTISING ASSOCIATION, THE, according to its printed constitution, is an organization "for the purpose of furthering the best interest of advertising." It is strictly a business association and is maintained by business men and advertisers in the belief that any organization that will improve advertising will thereby reduce the cost of advertising. There were in 1928 approximately 25,000 members of this association located in nine different countries. The parent association is made up primarily of: (a) local advertising clubs; (b) departmental organizations; (c) sustaining members; (d) members at large; (e) Better Business bureaux.

(a) Local advertising clubs are voluntary associations, whose purposes are usually: (1) to prevent false, deceptive and misleading advertising in the district in which the club exists; (2) to conduct study circles and present educational courses in advertising; (3) to hold local meetings which are addressed by leading business men on business and advertising topics of general interest. Upon the payment of the stipulated dues, the amount depending upon the number of members, the local club may become affiliated with the parent association. (b) Departmental organizations represent specific branches of advertising such as associations of newspaper publishers, trade-paper publishers, retail advertisers or advertising agents. (c) Sustaining members are either individuals or concerns interested in the improvement of advertising who contribute directly to the support of the International Advertising Association. (d) Members at large are individuals or concerns which wish to affiliate themselves with the parent association but which, because of their geographical location or for other reasons, are not able to join one of the auxiliary groups. (e) Better Business bureaux are organizations similar in nature to the local advertising clubs whose chief purpose is to protect advertising from false, deceptive or misleading claims. The Better Business bureau aids the local prosecuting attorney or other officials in securing evidence to convict fraudulent advertisers.

The organization of the International Advertising Association is extremely complex. First it is divided into 18 district subdivisions. The first 12 of these are made up of various groups of States in America; the 13th of the Philippine islands; the 14th of Great Britain and all countries in the British Empire except Canada, Australia and New Zealand; the 15th, of Canada, except British Columbia; the 16th, of Australia and New Zealand; the 17th, of all Europe except Great Britain and Ireland; and the 18th, of the Orient.

Once a year the International Advertising Association holds a convention which is attended by delegates from all of the various districts. This convention opens with addresses by delegates in the various churches of the city where the convention is entertained. The four following days are given over to discussions of the most prominent problems incident to the advertising, sale and distribution of goods and services. Many of the leading business men of the world have accepted invitations to address these conventions. Some of the sessions are given over to the discussion of technical questions by the various departmental organizations. Previous to 1929, the annual conventions were held in the United States, Great Britain and Canada. (H. E. A.)

INTERNATIONAL BUREAUX. The beginnings of the international movement may be traced back for more than a century. In 1823, for the first time, scientific congresses were held in Germany, to which representatives of other countries were invited. France, England and the United States soon followed this example. The need was soon felt for permanent bureaux to carry out decisions made. This was the origin of international bureaux, some official and some private bodies, dealing with the widest range of subjects: Agriculture, trade and industry; communications and transport; labour; medicine and hygiene; economics and finance; law and administration; arts and sciences; humanitarianism, religion, morals and education; sport and travel; feminism; international languages; bibliography and documentation; disarmament.

In 1909 there were 300 such bureaux; in Nov. 1912, 510. The World War was a serious hindrance to international life, and a large number of private bureaux were closed. After the war it took a long while to re-establish international relations. Many of these bureaux became inter-allied in character and several years passed before they again became really international.

An international handbook (*Annuaire de la vie internationale*) was founded in 1905, and published in 1905, 1906 and 1907 by the Institut international de la Paix. Another series was published in 1908-09 by the International Bibliographical Institute, and in 1912 by the Union of International Associations with the aid of the Carnegie Foundation. Since the World War the League of Nations has become the centre for international bureaux. Four editions of the *Handbook of International Organizations* have been published, in 1921, 1923, 1925 and 1926. Only such bureaux as replied to the questionnaire sent out by the secretariat of the League of Nations were included and, therefore, certain omissions were inevitable. Nevertheless, it can claim to give a fairly complete survey of international life at the present day. The last edition contains about 400 entries. This shows a decided decrease in the number of international bureaux since 1912. An examination of the dates of foundation discloses a still greater diminution; for, since 157 were founded after the World War and eight during the war, it follows that of the 510 bureaux recorded in 1912, 250 at most survived. These figures prove clearly the fatal effect of the war on international relations and the long time required for their re-establishment.

The geographical distribution of these international bureaux is of interest. Switzerland heads the list with 83 bureaux. Then comes France, 74; Great Britain, 63; Belgium, 60; the Netherlands, 40; the United States, 22; Germany, 19; Italy, 8; Austria, 6; Denmark, 6; Sweden, 4; other countries, 12, one in each. The importance of these bureaux varies greatly. Several will be found under separate headings (*see* RED CROSS, etc.). Bureaux founded on general treaties, that is to say, based on international conventions, signed by the various States, should be classed separately.

Bureaux Based on International Conventions (Addresses as in 1928). Advisory committee for the international protection of nature Founded, 1913. Seat, Basle: 22 Spitalstrasse.

Central international office for the control of the liquor traffic in Africa, 1919. Brussels: Ministry for Foreign Affairs.

Central Office for international railway transport, 1893. Berne: 36 rue Monbijou.

International bureau for the publication of customs tariffs, July 5, 1890. Brussels: 38, rue de l'Association.

International bureau of commercial statistics, 1913. Brussels: Ministry of Finance.

International bureau of the Pan American postal union, 1912. Montevideo.

International bureau of the telegraphic union, 1868. Berne: 1, Effingerstrasse.

International bureau of the universal postal union, 1874. Berne: 2, Schwanengasse.

International bureau of weights and measures, 1875. Paris: Parc de St. Cloud.

International Central-American office, 1908. Guatemala: 10a, calle Oriente, No. 1.

International commission for air navigation, July 11, 1922. Paris: 20, avenue Kléber.

International commission for the decennial revision of nosological nomenclature, 1900. No permanent secretariat.

International conference for promoting technical uniformity on railways, 1882. Berne: Federal Railway Department.

International conference for the study of epizootics, 1920. Paris.

International exchange service, 1886. Brussels: Belgian International Service, 45 rue des Longs-Chariots.

International hydrographic bureau, 1919. Monaco: 3 avenue du Port.

International institute of agriculture, 1905. Rome: Villa Umberto 1.

International institute of refrigeration, 1920. Paris: 9, avenue Carnot.

International prison commission, 1880. Groningen (Netherlands).

International public health office, 1907. Paris: 195 Bd. St. Germain.

Office of the American international union for the protection of trade marks, Dec. 6, 1927. La Havane: 55, calle de Trocadero.

Permanent court of arbitration, 1899. The Hague.

United international bureaux of industrial, literary and artistic property, 1885. Berne: 7 Helvetiastrasse.

Article 24 of the Covenant has defined the relations of the League of Nations with international bureaux in the following terms:

"There shall be placed under the direction of the League all international bureaux already established by general treaties if the parties to such treaties consent. All such international bureaux and all commissions for the regulation of matters of international interest hereafter constituted shall be placed under the direction of the League.

"In all matters of international interest which are regulated by general conventions but which are not placed under the control of international bureaux or commissions, the secretariat of the League shall, subject to the consent of the Council and if desired by the parties, collect and distribute all relevant information and shall render any other assistance which may be necessary or desirable.

"The Council may include as part of the expenses of the secretariat the expenses of any bureau or commission which is placed under the direction of the League."

In practice these relations have been, up to now, somewhat vague. Four international bureaux have been placed under the direction of the League: The international bureau for assistance, from June 1921; the international hydrographic bureau, from Oct. 2, 1921; the central international office for the control of the liquor traffic in Africa, from Jan. 11, 1922; and the international commission on air navigation, from July 1922.

The bureaux which existed before the League of Nations was founded show no eagerness to surrender their autonomy and merely maintain contact with the international bureaux section of the secretariat of the League of Nations—of which M. Nitobé (Japan) was the director for seven years, and since 1927, M. Dufour-Féronce (Germany).

The League of Nations publishes a quarterly bulletin of information on the work of international organizations, containing a summary of the proceedings of the congresses and conferences held in the period. Further, the League of Nations allocates to the Union of International Associations at Brussels a subsidy for the publication of a collection of international resolutions; vol. i. appeared in 1923. It contains the resolutions passed by 15 conferences and congresses. When it is remembered how many bureaux there are, it will be realized that an enormous number of volumes will be required to contain all their resolutions. (E. Cl.)

INTERNATIONAL CHAMBER OF COMMERCE, an important international institution established in 1920 at a meeting of the chief business interests of Belgium, France, Great Britain, Italy and the United States, and subsequently joined by 40 other nations, to promote the development of international trade, to remove or mitigate the effects of trade restrictions, and to foster harmonious commercial relations among the nations.

The machinery by which the Chamber seeks to attain its objects is as follows:—

The Chamber is governed by a council to which representatives are elected by the national committees in the various countries. The secretary-general carries out the decisions of the council under the supervision of the president and a small executive committee.

Committee organization is designed to cover important subjects which are brought before the council by the affiliated countries. There are committees for commercial policy and trade barriers; industrial statistics; international industrial agreements; fairs and exhibitions; international settlements and economic information; double taxation; bills of exchange, cheques and export commercial credits; international commercial arbitration; international protection of industrial property; trade terms; sea, air, rail and highway transport; and telegraph, telephone and postal services.

Biennially the International Chamber holds a congress in one of the affiliated countries, which is attended by delegates representing the different countries. These congresses are outstanding features of the organization. The congress which was held in Stockholm in 1927, was attended by 800 delegates from 35 different countries; previous congresses were held in Brussels (1925), Rome (1923) and London (1921). The congress of 1929 met at Amsterdam.

In each country which desires to participate in membership, there is established a national committee representing the industrial, commercial, financial and transport interests of the country. The national committees are the administrative and co-ordinating links between the council on the one hand and the actual members in their respective countries. The International Chamber has established a court of arbitration to facilitate the settlement of commercial disputes between the traders of different countries.

There are two categories of members. Organization members are representative bodies such as chambers of commerce, federations of manufacturers, etc. Individual firms and companies engaged in business activities are eligible for associate membership.

INTERNATIONAL DATE LINE. If a voyager travel eastward to the Antipodes and thus "anticipate the sun," his timing will be 12 hours in advance; if another travel westward, then his will be as much in arrear. There will thus be a difference of 24 hours when they meet. To avoid confusion, mariners chose the 180° meridian as a convenient line (known as the International Date Line), at the crossing of which they changed the name of the day, forward if going west; backwards if going east. The International Date Line, largely consequent on American initiative, while retaining the 180° meridian in the Pacific, is arranged so as to bring the Aleutian islands and Alaska into the same dating as America, and certain of the South Sea islands into the same dating as Australia and New Zealand.

INTERNATIONAL HARVESTER COMPANY, THE, for many years a leader in the manufacture of farm-operating equipment, and also a large manufacturer of farm and industrial tractors, motor trucks and coaches, was originally formed in 1902 under the laws of New Jersey, and acquired at that time the farm-implement properties and businesses of a number of old established concerns, notably the McCormick and Deering companies. In 1913 the company was divided into two organizations, the International Harvester Company of New Jersey and International Harvester Corporation, the latter taking over the foreign business and manufacture of tractors, motor trucks and other so-called "new lines." In 1918 the two companies were reunited into the present International Harvester Company. Manufacturing plants and binder twine mills are situated at: Chicago (5); Canton; Rock Falls and Rock Island, Ill.; Milwaukee; Auburn, N.Y.; Chattanooga, Tenn.; Fort Wayne and Richmond, Ind.; New Orleans, La.; St. Paul, Minn.; Springfield, O.; Chatham and Hamilton, Ont.; Croix, France; Neuss, Germany; and Norrköping, Sweden. The International Harvester Company leases iron mines in Minnesota and owns coal mines in Kentucky; it also owns steel furnaces and rolling mills in South Chicago, together with a by-product coke plant.

There are about 30 subsidiaries which represent three main groups of activity; manufacture, selling and transportation. An-

other activity is the purchase and sale of Manila fibre in both the Philippine Islands and the United States. The company also owns a plantation in the Province of Matanzas, Cuba, for the production of Mexican sisal fibre. For the three years 1924-26, inclusive, the company's reports showed a steady gain in net working capital. As of Dec. 31, 1926, total current assets were \$203,851,000, and total current liabilities \$34,449,000, leaving a net working capital of \$169,402,000. Other financial statistics for the year ending Dec. 31, 1926 were: Net income \$22,658,892; surplus for the year \$12,107,951; total surplus, \$77,042,890; and total assets \$307,824,282. The capital stock authorized is \$100,000,000 7% preferred cumulative (par \$100) and \$130,000,000 common (par \$100), of which on Dec. 31, 1926 there was outstanding \$65,568,400 preferred and \$99,876,772 common. The general offices of the company are at Chicago. (G. A. R.)

INTERNATIONAL INSTITUTE OF AGRICULTURE. An international institution founded in 1905 on the initiative of Victor Emmanuel III., king of Italy. A Californian merchant, David Lubin, convinced of the political as well as the economic importance of maintaining a proper balance between industrial and agricultural development, had come to the conclusion that in an age of international trade, of trusts, and concentrated capital, agriculture would be unable to hold its own in the economic arena against the coalesced forces of industry, commerce and finance unless organized effort, under government auspices, placed it in possession of a knowledge of crop conditions and available supply of farm products in all producing countries. He argued that on an international market, such as that for cereals, cotton, etc., prices are determined by world and not by national conditions, that information on these conditions was not then available for the farmer and the consumer as it was not procured for all countries through concerted, co-ordinated, international effort. Each country did as much or as little as it saw fit in the field of crop-reports, estimates, and statistics; reliable information was entirely missing for many important links in the chain of production; and this left the field open to the price manipulator whose activities affected injuriously farmers, traders, manufacturers and the public at large, disturbing the relative values of farm and industrial products, and replacing stability by speculation. After attempting in vain to draw the attention of persons in authority in the United States to the need of an initiative to ensure concerted effort in this field, Lubin came to Italy and laid his ideas before the king, who deeming the matter worthy of attention instructed his Government to enquire into it. On their favorable report the king took the initiative of inviting the Governments of all countries to Rome to consider the advisability of founding a permanent international organ for gathering, assembling and disseminating reliable information on the production and trade in agricultural staples and to study the needs of agriculture with regard to credit, co-operation, and marketing facilities. Thirty-six Governments answered the invitation, in May 1905 their representatives met in Rome, and signed a convention establishing in that city the International Institute of Agriculture.

The I.I.A., which opened its doors in 1908, was a pioneer in the field of international economic co-operation, being the first of those permanent official international organs which have since become so familiar a feature of the post-war world. Seventy-four Governments are affiliated to the institute which they support by annual contributions fixed by the convention of 1905 and subsequently raised to meet the depreciation of the currency in which they are paid.

In the field of crop reporting and agricultural statistics the I.I.A. has achieved much; largely as a result of its efforts these government services have greatly improved in the several countries, which send in their data regularly to the institute at Rome where they are summarized and published at monthly and sometimes more frequent intervals, thus keeping all concerned regularly posted on the expansion or shrinkage of actual and prospective supplies of the staples. With the financial assistance of the International Education Board it undertook in 1925 to organize the first international agricultural census to be taken in 1930-31 by all countries on a plan proposed by the institute to secure

comparable data. It follows the work done in the different countries in the science and practice of agriculture and in agricultural economics (credit, cooperation, marketing) its functions being informative. It promotes contacts in the agricultural world and for this purpose has organized a Permanent Committee of Agricultural Associations and an International Scientific Council consisting of 22 commissions of experts. It co-operates with the International Labour Office of Geneva through a Joint Advisory Agricultural Committee on which both bodies sit; it is represented on the Consultative Economic Committee of the League of Nations. It has become the recognized world centre for co-ordinating congresses on matters of interest to agriculture: soil chemistry, forestry, seed breeding, wheat growing, fertilizers, etc.

The I.L.A. is governed by a permanent committee of delegates appointed by the affiliated Governments, and by a general assembly of Government delegates meeting, as a rule, once every two years in Rome. The staff is international. The I.L.A. publishes a monthly Bulletin of Agricultural and Commercial Statistics, a monthly International Review of Agriculture, a Yearbook of Agricultural Statistics, a Yearbook of Agricultural Legislation, and a large number of special studies. (O. R. A.)

INTERNATIONAL LABOUR ORGANIZATION, THE. This organization was created in 1919 by Part XIII. of the Treaty of Versailles, headed "Labour." This part was reproduced in all the later peace treaties, appearing as Part XIII. of the Treaties of Saint Germain, Neuilly, Trianon, and Part XII. of the Treaty of Sèvres. These treaties are the first known to history to contain articles dealing with labour.

ORIGIN AND CONSTITUTION

The idea of protecting labour by international conventions may be traced back to the humanitarian theories of a handful of thinkers who over a century ago foresaw the necessity of establishing economic co-operation among the nations in order effectually to remedy the evils which might spring from the development of modern industry. The name of Robert Owen is often quoted as a pioneer of international Labour legislation on account of the two memoranda which he submitted to the Congress of Aachen in 1818. But though Owen was indisputably a pioneer of protective legislation, his memoranda do not contain the idea of an understanding between governments for the establishment of identical protective measures in favour of their wage-earners. A French industrialist, Daniel Le Grand, attempted to promote this idea between 1840-60. But it was only after 1890 that certain governments began to show an interest in it. A conference was held in Berlin, convened by the German Government, but it confined itself to enunciating a few very general principles. At last, in 1900 the idea took form when a private organization, encouraged and subsidized by certain governments, was formed under the name of the "International Association for Labour Legislation" with headquarters at Basle.

In 1905 a technical conference summoned by the Association worked out two draft labour conventions, the one dealing with the limitation of night work for women in industry, the other with the prohibition of the use of white phosphorus in the match industry. In 1906 a diplomatic conference adopted these drafts and a few states ratified them. A new technical conference was convoked in 1913 to regulate by new conventions the prohibition of night work for young persons employed in industry and to fix a 10-hour working day for women and young persons. The second diplomatic conference was due to assemble in the autumn of 1914. Meanwhile, the World War broke out. The work was taken up again and officially consecrated by the peace treaties which concluded the War of 1914-8.

Labour in the Peace Treaties.—The pre-War movement in favour of protection of labour was not in itself strong enough to enforce it. In most countries it was the work of intellectuals, legal experts, or politicians. With few exceptions (*e.g.*, Germany), the workers' organizations took little interest in it. But in almost all the belligerent States the War brought into prominence the share taken by the working classes in national defence and national life. The workers became conscious of this fact. As early

as Sept. 1914 a manifesto of the American Federation of Labor declared that peace should not be signed without the participation of representatives of Labour. In July 1916 at a conference at Leeds, of the trade unions of the Allied countries, in Oct. 1917 at a conference of the trade unions of the neutral countries and the Central Powers at Berne, and again at the conference of the inter-Allied Socialists at London in Sept. 1918, the same idea was taken up.

"The Treaty of Peace which will end the war and will assure to the peoples political-economic liberty and independence," said the London manifesto, "must also safeguard the working class of all countries from the attacks of international capitalist competition and assure it a minimum guarantee of moral and material order as regards labour legislation, trade union rights, migration, social insurance," etc.

Immediately after the War these tendencies grew far more pronounced. Revolutions had broken out in the conquered countries and their character had been invariably social. In the victorious countries the leaders of the governments pronounced, in accordance with the general feeling, that the working classes must receive a new place in the national communities. In Feb. 1919, at Berne, the trade unions of all European countries, allied, neutral, or defeated, claimed a labour charter and suggested that the old association, with its labour office, should be transformed into a great official organization of international labour legislation. A few days earlier (Jan. 29, 1919) the peace conference had resolved to constitute a commission for international labour legislation under the presidency of Samuel Gompers, and had called on it "to enquire into the international means necessary to secure common action on matters affecting the conditions of employment." The commission sat during February and March, 1919. It worked out a text which, having been adopted by the peace conference on April 11 and 28, 1919, became part XIII. of the Treaty of Versailles.

Principles and Procedure of the Organization.—A preamble at the head of Part XIII. defined as follows the principles which gave birth to the organization.

1. Universal peace, which it is the object of the League of Nations to establish, can be established only if it is based on social justice, and social justice implies the working out of equitable conditions of labour, which it is urgently necessary to apply.

2. The regulation of labour conditions must be accomplished internationally because "the failure of any nation to adopt humane conditions of labour is an obstacle in the way of other nations which desire to improve the conditions in their own countries."

3. Examples of the methods of improving conditions of labour were given: the establishment of a maximum working day and week, the prevention of unemployment, the provision of an adequate living wage, the protection of the worker against sickness, disease and injury arising out of his employment, the protection of children, young persons, and women, provision for old age and injury, protection of the interests of workers when employed in countries other than their own, recognition of the principle of freedom of association, the organization of vocational and technical education and other measures.

In another article (427) of the Treaty of Peace, these principles are formulated afresh and in a more precise form and recognized as "well fitted to guide the policy of the League of Nations" in industrial matters. These principles having been laid down, the Peace Treaty prescribed that a permanent organization should be established for their promotion. The commission, on meeting in Paris, was approached with proposals emanating from workers' representatives and even from certain states (such as Italy) which aimed at permitting a sort of international parliament to decree labour conditions which every state would be compelled to adopt. Such proposals appeared incompatible with the idea of national sovereignty as entertained by most states. The International Labour Organization, it was thought, should not form a "super-state," any more than the League of Nations. The Commission adopted as a basis of its deliberations a British draft which was more modest and, above all, more elastic, and attempted

to reconcile the independence of individual states with the authority of an official organization.

The system adopted was as follows: The International Labour Organization consists of two essential organs: the General Conference of representatives of the members, and an International Labour Office controlled by a governing body. The conference meets "from time to time as occasion may require and at least once in every year." It is composed of four delegates of each of the member states, of which two are government delegates and the two others represent respectively the employers and the workpeople. These last two delegates must be chosen by the governments in agreement with the industrial organizations, if such organizations exist, which are most representative of employers or workpeople, as the case may be, in their respective countries. This shows a characteristic feature of the new organization. In the Assembly of the League of Nations only Government delegates have seats, but in the Labour Organization delegates representing the employers and the workpeople of the member states intervene. This indicates the solidarity of economic and protective forces which has imposed itself on the world since the War.

The conference deals with questions which have been included in its agenda by the governing body, and the agenda is transmitted to the member governments four months before the meeting of the conference. At the close of its discussions it may adopt recommendations or draft conventions by a majority of two-thirds of the votes cast by the delegates present, but not otherwise. The member states undertake that, within a year at most from the closing of the session of the Conferences, or if special circumstances prevent this, in no case later than eighteen months, they will bring the recommendation or draft convention before the authorities within whose competence the matter lies, for the enactment of legislation or any other action. In the case of a recommendation the member states will inform the Secretary-General of the League of the action taken. In the case of a draft convention the member will, if it obtains the consent of the proper authorities, communicate the formal ratification of the convention to the Secretary-General and will take all necessary action to make the convention effective.

It is necessary to consider the exact weight which the system carries. The states, under the Peace Treaty, have not undertaken to ratify automatically all draft conventions adopted by the International Labour Conference, but only to submit the drafts to the authorities competent to enact the legislation. They are still free to ratify or not. But when there was only the International Association for Labour Legislation, before the War, the states which had sent plenipotentiaries to the diplomatic conferences were not even bound to approach their parliaments with the resolutions adopted. The obligation which they have now undertaken may seem to carry little weight, since each state remains free, within its sovereign rights, to ratify or not; but in essence the whole system rests on an appeal to the public opinion of each of these states, and an appeal to parliament, the authoritative expression of this opinion. The whole mechanism invented by the negotiations of the treaty constitutes an act of faith in the feeling of justice which should animate corporate humanity.

Once the conventions have been ratified, the mechanism of their application instituted by the Peace Treaty develops in the following manner: by the act of ratification the states contract a mutual agreement to respect equally all clauses contained in a convention. They must allow mutual supervision of their application of these clauses. By Art. 408 of the Treaty of Versailles they undertake to send an annual report to the conference in which they give a list of the measures for such application. Comparison of these reports may always form the subject of discussion at the conference. It may be noted that, to facilitate this discussion, the Conference decided at its Eighth Session to set up a committee to examine the summaries of these reports. To prepare for this work, the Conference also invited the governing body to appoint a technical committee of experts. The committee of experts met for the first time in 1927 and submitted a report to the governing body, which was transmitted to the Conference. If one of the

ratifying states fails to apply the convention, or applies it imperfectly, other ratifying states, or even industrial associations of employers or of workers, may file complaints. When such complaints are received, the governing body of the International Labour Office must deal with them. If necessary it may submit the complaint to a commission of enquiry (Art. 411-414). In the last instance, The Permanent Court of International Justice can be called on to pronounce judgment. This court may even, under Art. 418, indicate the measures, if any, of an economic character which it considers to be appropriate and which other governments would be justified in adopting against a defaulting government.

THE I.L.O. IN OPERATION

The first conference was convoked at Washington in Oct. 1919. The International Office was not yet constituted. The programme of the conference had been fixed in the Peace Treaty itself, and a committee of organization entrusted with its preparation. Six draft conventions were voted concerning: (1) The limitation of hours of work in industrial establishments to eight hours a day and 48 hours a week. (2) Unemployment. (3) The employment of women before and after child-birth. (4) Night work for women. (5) The minimum age for the admission of children to industrial employment. (6) Night work for young persons in industry. The Washington conference constituted the International Labour Office, and nominated its first governing body. This governing body appointed the director, M. Albert Thomas. In 1920 a conference was held at Genoa, which was devoted to maritime questions and passed three draft conventions. The first fixed the age of admission to work at sea, the second dealt with unemployment benefit in case of loss by shipwreck, the third dealt with finding employment for seamen.

In 1921 the third session at Geneva voted seven draft conventions dealing with: (1) The age of admission for children to agricultural employment. (2) The right of association and combination of agricultural labourers. (3) Workmen's compensation in agriculture. (4) The use of white lead in painting. (5) The application of the weekly rest to industrial establishments. (6) The minimum age of admission of young persons to employment as trimmers or stokers. (7) The compulsory medical examination of children and young persons employed at sea. Each of these sessions voted at the same time a number of recommendations.

The fourth session at Geneva in 1922 only voted a recommendation concerning statistical and other information relative to emigration and immigration. The fifth session at Geneva in 1923 also voted only one recommendation concerning general principles for the organization of inspection services to ensure the applications of laws and regulations for the protection of the workers. The sixth session at Geneva in 1924 instituted the procedure of giving the conventions two readings, at intervals of one year. Some conventions were thus given a first reading, most of them being voted in 1925. The session of 1924 definitely passed one recommendation only concerning the utilization of the spare time of workers. The seventh session, Geneva, 1925, finally voted four draft conventions concerning (1) workmen's compensation for accidents, (2) workmen's compensation for occupational diseases, (3) equality of treatment for national and foreign workers in workmen's compensation for accidents, (4) night work in bakeries.

The eighth session, Geneva, 1926, adopted a draft convention concerning the simplification of the inspection of emigrants on board ship; and the ninth session, also held in Geneva in 1926, adopted two draft conventions concerning respectively seamen's articles of agreement and the repatriation of seamen. The tenth session, Geneva, 1927, adopted two draft conventions on sickness insurance, one for workers in industry and commerce and domestic servants, and the other for agricultural workers. At all these sessions recommendations also were adopted. The 1927 session of the Conference put into operation for the first time a new procedure, known as the "double discussion" procedure. According to this system, a question placed on the agenda of the Conference by the governing body will, at the first of two successive sessions,

form the subject of a general discussion, and if the Conference considers that it is suitable for a convention or recommendation, it will determine the form of the questionnaire to be sent to governments with a view to the detailed examination of the question at the succeeding session of the Conference.

In all, not counting recommendations, 25 International Labour conventions were submitted to the States for ratification between 1919 and 1927. These conventions dealt with industry, commerce and, in some cases, navigation and agriculture. As regards agriculture a dispute arose in 1921. It was maintained that the International Labour Organization had not the right, under the Peace Treaty, to deal with the protection of agricultural labourers. On this point an advisory opinion of the Permanent Court of International Justice was taken through the mediation of the League of Nations under Art. 14 of the Peace Treaty. The Permanent Court gave a judgment recognizing the competence of the International Labour Organization.

Ratifications.—In Oct. 1927, the League of Nations had registered 243 ratifications. This figure has given rise to much discussion. The International Labour Organization includes 55 States. If one excepts the conventions adopted since 1925, not many of which had been ratified by 1927, about 900 acts of ratification could in theory have taken place for the other 16 conventions. There have been only 224 ratifications, that is, about one-fourth of the total possible. But this low figure calls for certain remarks. The same value cannot be attached to all ratifications.

1. There are a certain number of conventions which could not be ratified by all States, despite their general character. The maritime conventions, for example, do not interest the States which have neither coasts nor ships. Similarly, there are countries of small proprietors where the number of wage-earning agricultural labourers is quite insignificant. There are others, again, where certain unhealthy industries against which conventions are directed, have not established themselves.

2. There are numerous States in which industry is of little importance and where national labour legislation hardly exists. The Hejâz, Siam and other states have indicated that the measures laid down in certain conventions are inapplicable to the conditions under which the wage-earning labourers in these countries work.

3. International action is only beginning, and all sorts of reasons delay ratification; not merely the inexperience and inattention of the great national administrations, for which the international conventions are often matters of secondary importance, but also the hesitation to contract obligations which sometimes appear to threaten the output, or at least the competitive capacity, of the country on the international market.

Nevertheless, important results have been obtained. In the eight years preceding the War the two conventions of Berne had been ratified by a very few states only. When, since the World War, such conventions as that which forbids night work for women or that which attempts to cope with unemployment have obtained the ratification of 16 or 20 states, including great industrial countries like Great Britain, France or Italy, many thousands of workpeople are definitely assured of the benefits of reform. For, under the text of the conventions, the contracting states cannot, for a period of 10 years, go back on the obligations which they have assumed, even in crises where they would be tempted to do so. The effect of the ratifications has been also particularly important in certain countries, for example in India, where conditions of labour have been greatly improved by the application of the measures contained in the international conventions.

But even when the conventions are not ratified, they become the model on which the new national legislations form themselves. Belgium, for example, before it ratified the convention, established the eight-hour day in 1921 in strict conformity with the clauses of the Washington Hours Convention. Similarly, all the young states of Central and Eastern Europe which were formed or resuscitated in 1919 have modelled their entire labour legislation on the general rules laid down by the International Labour Organization. Thus, more progress has been achieved than might be imagined.

A Centre of Information.—The work of the International

Labour Organization is not confined to preparing the international conventions, to seeking to obtain their ratification by the states, or to watching over their application. Art. 396 of the Peace Treaty also assigns it further functions which include the "collection and distribution of information on all subjects relating to the international adjustment of conditions of industrial life and labour." Also "the conduct of such special investigation as may be ordered by the conference." It has "to edit and publish in French and English . . . a periodical paper." The conference may even assign to it, besides the functions mentioned above, "such other powers and duties" as it chooses.

Thus, since 1919, the International Labour Office has become a sort of great clearing house of all information on social questions. It has a library of 150,000 volumes. The ideal would be to make it a centre where workers would be certain of finding all publications of all countries touching on the regulation of labour. This office collects by means of corresponding offices in Paris, Rome, Berlin, London, Washington and Tokyo, and collaborators in other capitals, periodical information on social developments in most great countries. It publishes two general periodicals: the weekly *Industrial and Labour Information*, which gives important news in the various branches of social life, and a scientific monthly review, the *International Labour Review*. It further publishes the *Industrial Safety Survey*, which reports all new measures taken and all experiences obtained regarding safety of labour; and a *Monthly Record of Migration*. It publishes reviews or bulletins giving a summary of all these publications for the information of different countries, in German in Berlin, in Italian in Rome, in Spanish in Madrid, and in Japanese in Tokyo. Carrying on the tradition inaugurated by the Basle office, it publishes an annual collection, in French, English and German, of the labour legislation promulgated every year in different countries (*Legislative Series*). It has undertaken enquiries on a large scale in all matters of particular importance. Among them may be mentioned the great *Enquête sur la Production* which deals with the economic situation of the world between 1918 and 1925; an enquiry into the conditions of labour in all the coal producing countries; an enquiry into legislation and labour conditions in Russia; another into labour conditions in Asia, etc. It publishes quarterly a *Bibliography of Industrial Hygiene*.

The I.L.O. has also attempted to simplify and unify methods of labour statistics used in different countries. Three conferences of labour statisticians have already been convoked, and corresponding committees, consultations of experts and special commissions, permit the Office to maintain contact with technicians and scientists in the various branches of social life.

Internal Organization of the Office.—In order to deal with its twofold task of maintaining contact with the governments, and especially with the Ministries of Labour, with which it corresponds directly under Art. 397 of the Treaty, and with the organizations of workers or employers, the Office has had to organize itself on a sound basis. Under the Peace Treaty it is administered by a governing body nominated for three years by the Conference. The governing body consists of 24 members, of which 12 represent the governments, six the employers and six the workers. Of the 12 government representatives eight belong *ex officio* to the most important industrial countries (Germany, Belgium, Canada, France, Great Britain, India, Italy and Japan). If any dispute arises about relative industrial importance, this must be settled by the Council of the League of Nations. A system of indices (based on population, working population in relation to the total population, steam horse-power, length of railway lines, etc.) makes it possible to decide this point. The six workers' representatives are nominated by the delegates to the Conference representing the workers, and the six employers' representatives by the employers' delegates. The Conference has proposed to enlarge the governing body, but this will need the amendment of the Peace Treaty, and it has not yet been done on account of the slow procedure for the ratification of such amendments.

The governing body nominates a director and gives him his instructions. The director nominated in 1920 was M. Albert Thomas, formerly a French Minister of State. He is assisted by

a deputy director, who is an Englishman, Mr. Harold B. Butler. The staff of the International Labour Office amounted in 1927 to about 376 employees of all ranks, who were drawn from 32 different nationalities. Under Art. 395 of the Peace Treaty the director "shall as far as possible, with due regard to the efficiency of the work of the office, select persons of different nationalities." The nations chiefly represented among the personnel are France and Great Britain, because French and English are the two official languages used by the office; next, Switzerland, because the executive personnel is recruited locally.

The budget of the office varies between 7,000,000 and 8,000,000 gold francs, and is introduced annually by the governing body before the Assembly of the League of Nations. It is supplied for the most part by contributions from the states which are members of the Organization. This contribution is fixed under a scale adopted by the League of Nations for its own contributions.

Relation to the League.—The International Labour Organization is, in fact, part of the organization of the League. For this reason, since 1920 it has been established at Geneva. It was first installed in an old college. In 1922 the sum of 3,000,000 gold francs was voted for the erection of a suitable building on a site which had been given for the purpose by the Swiss Federation. The I.L.O., though attached to the League of Nations, entitled to its assistance, when required, and receiving its funds through the League, is nevertheless, like the Permanent Court of International Justice, an autonomous institution. Its decisions are not subject to the control of the Council of the League. The director of the office is in no way subordinate to the Secretary-General of the League. Indeed, if membership of the League carries with it membership of the I.L.O. (Art. 387), it was decided by the persons who negotiated the Peace Treaty, as by the Assembly of the League of Nations in 1921, that states which are not members of the League can become members of the I.L.O. Thus, since 1919 Germany belonged to the I.L.O. with equal rights before being a member of the League. A representative of the German Government has always sat on the governing body; the workers' group has regularly elected a German member, and the employers have also, since 1922, had a German member in the governing body. There are German employees throughout the office. In order to gain general information and to carry through scientific research, the I.L.O. remains in almost daily contact with the U.S.A. and with Soviet Russia, the only two great states which, for various reasons, do not belong to the organization.

ACHIEVEMENTS AND GENERAL AIMS

The organization has often been criticized and reproached with the desire to exceed the limits of its competence. The Permanent Court of International Justice decided in the two cases brought before it that this criticism was not justified. It has also been reproached with being exclusively guided by the workers' interests, and even with being unduly influenced by Socialist thought. Yet no concrete case can be urged in support of such an accusation against the director, or even less against the governing body. But one fact must not be forgotten, which was brought out in 1921 by a report of the Commission of Enquiry of the League of Nations: the International Labour Office is not simply an organ of conciliation or for keeping the balance between various industrial interests; it must look for conciliation only in order to attain a definite end, which is to realize the programme drawn up in the preamble to Part XIII. of the Peace Treaty. Experience also shows that measures protecting workmen are never fully carried through unless they are made by agreement with the workers and unless the workers are interested in their application.

The International Labour Organization, as conceived and conducted since 1919, has been able to keep the sympathies and confidence of the important workers' organizations. It is true that the Communists, the leaders of the Third International, have violently attacked it. But the International Federation of Amsterdam, with its 13,000,000 members, the Christian Unions, the Italian Fascist organization, take a regular part in the conferences of Geneva, and demand that the conventions be applied. It is to be noted also that the employers continue to be represented at the conferences

and on the governing body. The International Labour Organization, while it aims at bringing about the "wellbeing, physical, moral and intellectual, of the wage-earners," attempts at the same time to take account both of the interests of production, and (to quote Art. 427 of the Peace Treaty) of the "differences of climate, habits and customs, of economic opportunity and industrial tradition," which "make strict uniformity in the conditions of labour difficult of immediate attainment."

As the Preamble to Part XIII. of the Treaty indicates, the objects in view are two-fold: to protect the various countries against unfair competition based on the exploitation of the workers, and also, directly and spontaneously, to enable the workers to enjoy a higher standard of living and work. The aim is not merely to create a balance between different countries, but also to give just treatment to individuals. Even if the first object has lost some of its force, the second is as important as ever. Whatever may be the vicissitudes of political life, and however much the tide of the labour movement may ebb and flow in the industrial communities of the world, the need for social justice continues to be strongly felt. Further, from the general point of view, the I.L.O. has helped to popularize among the industrial masses, both of the workers and of the employers, the idea of a definite peace based on an economic understanding and the social solidarity of the nations. It is already the great centre of international collaboration. It is recognized as being one of the great factors of peace. Its history bears witness to all the difficulties attending new international creations. The life of a nation enjoys the natural support of geographical contiguity, of racial community and of age-long tradition. An international organization can come to birth and live only if public opinion and the judgment of the governments favour a common programme. It appears that the programme of social justice drawn up in the Peace Treaty has sufficient authority and sufficient reason to assure the existence of the International Labour Organization.

BIBLIOGRAPHY.—See *The Treaty of Peace between the Allied and Associated Powers and Germany*, Part xiii. (H.M. Stationery Office, London, 1925). A list of publications of the International Labour Office can be obtained from the Publications Department of the Office at Geneva, or from their correspondents in different countries. (A. TH.)

INTERNATIONAL LAW, PRIVATE. Private international law means that law which is applied to the judicial adjustment of divergent private interests of an international character, whether between individuals or an individual and a State, as distinguished from the law applicable to the settlement of relations between States, which is called public international law. The court necessarily determines which State-law has to be applied, since, *ex hypothesi*, the persons interested or the circumstances are related to different States with differing systems of law which meet in competition. Hence comes the expression "conflict of law or laws" used by some writers.

Certain States which have codified most of their law have included some main rules of international law, *e.g.*, the statute introducing the German Civil Code, while other countries have been parties to treaties on the subject and in both classes the rules become binding on their courts. The most prominent series of conventions in Europe are those of The Hague, one being of Nov. 14, 1896, three of June 12, 1902 and four of July 19, 1905 selecting the rules on the validity of marriage and marriage contracts, their effects on property and status, divorce and judicial separation, guardianship of minors and interdicted persons, testamentary and intestate succession and parts of judicial procedure. It seems that Germany, Italy, Holland, Portugal, Rumania and Sweden are parties to all these conventions of 1902 and 1905 while Austria and Switzerland are parties to those on the validity of marriage, divorce and separation and guardianship of minors; but France and Belgium have since renounced on grounds of public order.

In Ibero-America we have the several treaties of Montevideo of 1889 signed by the republics of Argentina, Bolivia, Paraguay, Peru and Uruguay, dealing with domicil, capacity, family rights, property, juridical acts, marriage settlements, successions, prescription, jurisdiction, commercial law, maritime law, bills of exchange, bankruptcy, etc.

Personal Law.—Great Britain did not sign any of the above Hague Conventions, and this chiefly was for the very good reason that personal law, as conceived by the signatories, means the law of the nationality, while in Great Britain and nearly all the British colonies it means the law of the domicile; the whole basis therefore of these conventions was alien to the theory that a man's personal law by which he means and expects his rights to be governed is that of his domicile, *i.e.*, the country in which he has established himself and with whose conception of legal relations he must be deemed to have identified himself. The opposing theory treats him as carrying about with him the law of his nationality.

"Domicil" (*q.v.*) primarily refers to the domicile of his father at the child's birth, known as his domicile of origin, which he can change; but he must actually remove himself and become resident in another country, intending that to be his new home with no present intention of leaving it, so that there must be a combination of fact and intention. An English court judges acquisition of a new domicile without regard to the law of the place where the new abode is constituted (*Casdagli v. Casdagli*, 1919, A.C. 145; *In re Annesley*, *post*). The English law cannot conceive of a man without a domicile, and therefore when in doubt as to the acquisition or abandonment of a new one, it treats him as having still or reverting to his domicile of origin. Some foreign systems, *e.g.*, the Argentine, when it cannot discover his domicile, treats him as domiciled where he actually is.

Renvoi.—The necessity of applying foreign law to the solution of the forensic difficulties which arise between two systems of law, one of which applies the personal law of nationality and the other that of the domicile, has given birth to the doctrine of *renvoi*, which chiefly concerns successions. The problem, first recognized in France in the Forgo case (Clunet, 1883, 64), may be stated as follows. When an Englishman dies domiciled in France, the French court applies to his succession the law of his nationality, that being his personal law as conceived in France, and it treats the English law, including English international law, as being that personal law of nationality, although in fact there is strictly speaking no English law for nationals. It discovers that an English court would apply the law of the deceased's domicile to the succession, that being in fact the internal law of France, with the result that the French court under the doctrine of *renvoi* applies the French internal law to the succession. In the case of *In re Annesley*, 1926, Chancery at p. 707, the court recognized and followed the French law of *renvoi*, but the judge suggested that the same result would follow by rejecting the same doctrine as being part of English law; which means that if the succession was open in England instead of France, the English court would apply the French internal law as being the law of the domicile and would not enquire whether or not the French court would throw back to the internal law of England as the law of the deceased's nationality. In the result, both courts would apply the same law of succession and this solution has the virtue of simplicity, but it is not yet settled that England rejects the doctrine as being part of its own law.

While domicile formed the usual criterion in the later middle ages and onwards, it was subjected to a considerable reverse by the Civil Code of the French, commonly called the Code Napoleon, under the influence of intense national feeling, and nationality now governs France and the many nations which have followed her lead, *e.g.*, Belgium, Germany, Holland, Italy, Spain, etc., though it is nowhere possible entirely to discard the former rule in all legal relations. England and the States and colonies which derive from her, as well as Scotland and Ireland and the United States, adhere to the domicile theory and this is the case in most Spanish-American States, chiefly for the reason that States receiving large numbers of immigrants find it the most convenient rule.

In commercial matters English courts were slow to recognize personal law and as late as Lord Eldon's time they held that the capacity of a person to contract depended on the law of the place where the contract was made. Perhaps unfortunately, this has since been discarded in dicta of the personal law, but in the

United States this is not universally the case, while Dicey in his *Conflict of Laws* suggests that the old rule still applies to ordinary commercial contracts.

By German law, "if a foreigner in Germany enters into a legal transaction for which he is not competent or is restricted in his competency, he is to be deemed competent as to such transaction to the extent that he would be competent by German law. This, however, does not apply to transactions relating to family rights or succession or dispositions of foreign immovables." It would seem from Pillet (*Droit Int. Privé*, 176) that after some vacillation the French decisions only protect contractants on French soil in the case of fraud by a contracting foreign incapable. Guardians, tutors, curators of minors have authority from the country which appoints them, whether it be that of the domicile or the nation. There is some doubt whether in France a guardian can trade on behalf of a foreign minor (*Valery, Droit Int. Privé*, 893).

A British court will not entertain a petition for divorce unless the husband is domiciled within its jurisdiction; but many foreign countries, basing competence on residence, apply the national law of the parties. There is some doubt whether countries like Spain, which does not admit divorce *a vinculo* within its jurisdiction, will recognize the divorce of a Spanish subject by a foreign competent court. Legitimation by subsequent marriage of the parents depends also on the personal law of the father as determined either by domicile or nationality. English law, in the absence of express contract, considers the law of the husband's domicile to govern the effect of marriage and that of a settlement of personal property; but this domicile may be a new domicile chosen to be the immediate home of the newly married, in each case known as the matrimonial domicile (*Peters v. Quebec Cité*, 1908, 33 Quebec Sup. Court. 361; *Union Government v. Larkan*, 1916, S. Africa, A.D. 212).

Personal property is for the purpose of succession treated as forming one mass located in the place where the succession is "opened," *i.e.*, generally the domicile of the deceased. Until 1926, few countries except England and those deriving from her, caused real property to descend in a different manner from personal property. These conditions, however, have been altered by the Administration of Estates Act, 1925, real property and personalty now descending in the same manner. It is remarkable that, while property relations as between husband and wife are governed by the law of the matrimonial domicile, although this be abandoned (*De Nicolls v. Curlier*, 1900, A.C. p. 33), this does not apply to rights of succession, which change with change of domicile.

Lex Situs.—The law of the territory in which they are situate governs immovables in almost every particular, although English practice in the sphere of jurisdiction admits of certain personal processes such as injunction and accounting. An action for the sum of money secured by a foreign mortgage is also allowed, for the reason that the security is subsidiary to the debt, but the court will go further and even order the foreclosure of the mortgage in default of payment. This cannot often happen since in some countries, such as Ireland, foreclosure is unknown and in many colonies the right is severely restricted, while the system of conveyancing, where it does not consist in conveying the estate to the mortgagee, does not admit of foreclosure. This is necessarily the case under the Torrens system of registration (*see Burge, Colonial and Foreign Laws*, v. pt. ii, ed. W. A. Bewes). By way of illustrating the principal rule, the law which, in the absence of agreement, imposes community of assets on husband and wife cannot in the Cape be evaded by a postnuptial agreement valid in Natal where it was made (*Union Government v. Larkan*, *supra*). It may in passing be said that property given to a wife for her separate use is not within the classes of property to which community applies (*De Serre v. Clarke*, L.R. 18 Equity, 587); but this decision may be open to exceptions.

Lex Loci Actus.—The form of a document and the validity of its execution, *i.e.*, its extrinsic qualities, are governed by the law of the place where it is executed, in the absence of any evidence to the contrary. Its intrinsic qualities, which affect the country where its performance is to take place, are controlled by the law of the latter place; where it will not be enforced if it is *contra*

bonos mores, contrary to any positive law or public policy (see *Law Quarterly Review* for 1921, xxxvii. 3, 5). There also the capacity of the parties, etc., may be considered. In countries where a system of registration of documents is essential for complete security or, as sometimes, for any operative effect, it is necessary that the document should be such as can be registered in the place where it is to take effect. This is specially so in the case of immovables. There is an exception to the general rule in the case of a will of personal property; for Lord Kingsdown's act of 1861 legalized three forms of will made by a British subject abroad besides that of his last domicile, viz., that of the place where the will is made, that of the testator's domicile at the time when the will is made, that of his domicile of origin, when in the British dominions; but the last does not apply to a will offered for proof in Great Britain. Another exception occurs in England where an instrument affecting land within the meaning of the Statute of Frauds must conform to its requirements wherever it is made (*Leroux v. Brown*, 1852, 12 C.B. 801). Not all nations are as strict as the English in rejecting documents in foreign form affecting immovables.

Lex Loci Contractus.—The law of the contract is generally the same thing as the law of the instrument. If they differ, an English court would enquire what is the proper law of the contract, with a tendency to favour the place where it is to be carried out (*lex loci solutionis*). This again is chiefly a matter of the intrinsic qualities of the contract. The contract of marriage must usually conform to the law of the place of the marriage, but exceptions are allowed under such laws as the Foreign Marriage Act 1892, which, however, in the absence of treaties, are not always binding on other Powers.

The law of the practice of the court (*lex fori*) naturally governs any action whether of an international character or not, and this rule includes the form and remedy. Prescription and limitation of actions are usually treated as belonging to this law, but when a right has become non-existent by the law which properly governs it, it will not be enforced anywhere else.

Foreign Judgments.—Rights which have been declared by a judgment of a competent foreign court have sometimes to be enforced in another country. In England such judgments, whether of foreign or colonial courts, are enforced by action, treating the sum of money awarded as due under the fiction of a promise to pay. Unlike the practice in many countries, no enquiry is allowed into the merits; but a defence is open on the ground of absence of jurisdiction, and since the action is on contract, defences as on contract are allowed. Declaratory judgments of rights of property are founded on territorial jurisdiction, while those of status depend on domicile or nationality as the case may be. No *exequatur* is required in either case. Judgments *in personam* when to be enforced abroad, e.g., on contract or for a wrong, must be clothed with an order called *exequatur*, i.e., "let it be carried out," and then the original judgment is executed and no new judgment is pronounced, as in England. This system in a reciprocal form has been introduced into the British empire under the Administration of Justice Act 1920, and by c. 33 of the same year, reciprocal enforcement of maintenance orders (other than affiliation orders) was provided for. It is to be noticed that many countries assume greater jurisdiction than is acquiesced in by other countries, but this excessive claim is, of course, valid for internal purposes. Under the doctrine of reciprocal treatment as between States, so popular on the Continent, the foreign courts will often refuse to enforce an English judgment except in the English way, which involves a new action.

(W. A. B.)

BIBLIOGRAPHY.—The best authority on the history of private international law to the end of the 18th century is Lainé, *Introduction au droit international privé* (2 vols., 1888). See also L. v. Bar, *The Theory and Practice of Private International Law* (Eng. trans. 1892); Bate, *Notes on the Doctrine of Renvoi* (1904); J. Westlake, *A Treatise on Private International Law* (7th ed., 1925); A. V. Dicey, *Conflict of Laws* (ed. A. B. Keith, 4th ed., 1927).

UNITED STATES

The topic under consideration is almost universally called the conflict of laws, following the usage of Judge Story's classic

treatise. Since each State of the United States is from the point of view of its law independent of each other State, and since every transaction of importance has an inter-State character, occasions for the application of the principles of private international law are much more frequent than in England and the law has therefore been much more fully developed by the courts.

Jurisdiction.—At the outset one is met with the question of jurisdiction, that is (for this purpose) the power of a State, with or without judicial action, to create legal interests which other States will recognize and enforce. Jurisdiction may be obtained in three ways: by physical power, by legal relation and by submission.

(a) Within the territory of a nation or State there is jurisdiction over every person or thing in it, except as such jurisdiction is prevented by some principle of public international law, such as the protection extended to ambassadors. Where, however, a thing is carried into a State by the act of God, as by a tempest, jurisdiction, at least for some purposes, is not exercised over it till the owner has a chance to remove it, and the same rule is followed where property is brought in by a wrongdoer, without the will or procurement of the owner (*Edgerly v. Bush*, 81 New York 199). A full jurisdiction is not exercised over a vessel temporarily in port (*Hays v. S. S. Co.*, 17 How. [U.S.] 596; *Brown v. Duchesne*, 19 How. [U.S.] 183) or over railroad cars passing through the territory (*P. P. Car Co. v. Pennsylvania*, 141 U.S. 18).

(b) The relation of allegiance to a nation, or of domicile within a State even though it is a division of a nation, is a ground for exercising jurisdiction. Thus, the United States may impose a tax upon its citizen (*Cook v. Tait*, 265 U.S. 47) and any State upon its domiciliary (*Kuntz v. Davidson County*, 6 Lea [Tenn.] 65); so a court of one of the United States may render a judgment against its domiciliary (*Henderson v. Staniford*, 105 Massachusetts 504).

(c) Submission to jurisdiction may be established by express consent of the subjected person, as by appearance in court or by accepting the terms of a contract to that effect (*Grover and Baker S. M. Co. v. Radcliffe*, 137 U.S. 287). Submission may also be established by proof that the subjected person has voluntarily caused an event to happen within the State, and is thereby submitted to any legal consequence of the event; or has permitted a thing in which he has property to be within the State, whereby his interest in the thing is subjected to the jurisdiction of the State.

Jurisdiction to reach by garnishment a claim due to one's debtor rests upon jurisdiction over the garnishee (*Harris v. Balk*, 198 U.S. 215).

Jurisdiction to grant a divorce depends upon the domicile of the spouses. Ordinarily both have the same domicile. A wife may, however, acquire a domicile separate from her husband (*Williamson v. Osenton*, 232 U.S. 619), and in that case neither party can obtain a legal divorce at a new domicile unless the other spouse has consented to the separate home or by his misconduct caused it, or has appeared in the proceedings (*Haddock v. Haddock*, 201 U.S. 562; *Bonner v. Reandrew*, 203 Iowa 1355).

Marriage is governed in the last analysis by the law of the domicile of the parties; but it is based upon a valid agreement of marriage, and the validity of that agreement is governed by the law of the place of marriage (*Commonwealth v. Lane*, 113 Massachusetts 458). Legitimacy is governed by the law of the domicile of the parent with whom the relation is to be established, whether at birth (*Moore v. Saxton*, 90 Connecticut 164) or from the later time of legitimation (*Scott v. Key*, 11 Louisiana Annual 232).

Property.—All immovable property is governed in all respects by the law of the country where it is situated (*Clark v. Graham*, 6 Wheaton [U.S.] 577). The transfer of title to chattels *inter vivos* is governed by the law of the place of the chattels at the time of transfer. This title once accrued will ordinarily be recognized in any State into which the chattels are brought (*Emery v. Clough*, 63 New Hampshire 552). Where, however, a mortgage or other lien on a chattel is created in one State, and all require-

ments of the law of that State are satisfied, it is held in some States that if brought into another State the lien will not be recognized unless the requirements of the second State for the recognition of such liens are satisfied (*Hervey v. Rhode Island Locomotive Works*, 93 U.S. 664), but the preferable and prevailing view is otherwise (*Langworthy v. Little*, 12 Cushing [Mass.] 109). The administration of a trust of chattels is governed by the law of the State where the creator of the trust intended the trust to be managed (*Greenough v. Osgood*, 235 Massachusetts 235). The inheritance of movables, while governed in the last resort by the law of the situs, is determined by the law of the domicile of the deceased owner at the time of his death (*Moultrie v. Hunt*, 23 New York 394). Upon the marriage of an owner of movable property, the other spouse acquires such an interest in the property then held as is given by the law of the husband's domicile at the time of marriage (*Harral v. Harral*, 39 New Jersey Equity 279).

Contracts.—Capacity to enter into a contract, including a contract of marriage, is governed by the law of the place of contracting (*Milliken v. Pratt*, 125 Massachusetts 374); and the form necessary for the validity of the contract is governed by the same law (*Scudder v. Union National Bank*, 91 U.S. 406). There is great difference of opinion as to what law determines whether an agreement which is in due form is legally binding. Some courts hold that this is determined by the law of the place of contracting; some, by the law of the place of performance; some follow the English rule, and determine the validity of the contract by the law intended by the parties. The first view is the best accredited, and is likely to prevail.

Questions as to the performance or breach of a contract depend upon the law of the place of performance. Thus the acts required of sureties are those laid down at the place for the principal to perform (*Cox v. U.S.*, 6 Peters [U.S.] 172). What constitutes payment (*Graham v. Bank*, 84 New York 393), the time for payment (*Stebbins v. Leowolf*, 3 Cushing [Mass.] 137), the allowance of days of grace on a note (*Bowen v. Newell*, 13 New York 290), the proper medium of payment (*Benmers v. Clemens*, 58 Pennsylvania 24), the rate of interest and the measure of damages, all depend upon the law of the place of payment. The form of protest for non-payment of a bill is also regulated by the law of the place of payment, but the necessity for notice of non-payment of a bill and the nature of the notice depend upon the law of the place where the obligation arises (*Aymar v. Sheldon*, 12 Wendell [N.Y.] 439). The validity of an assignment of a contract is determined by the law of the place of assignment (*Müller v. Campbell*, 140 New York 547).

Wrongs.—The law governing an act or its result is the law of the State where the act or resulting event took place; the State where any proximate result of an act takes place may make that event wrongful. Whether the result was a legal wrong is determined by the law of the place where it happened (*American Banana Co. v. United Fruit Co.*, 213 U.S. 347); whether the act itself was justified is determined by the law of the State where the actor did his act.

Judgments.—A foreign judgment creates an obligation which is both recognized and enforced in another State, whether the judgment is at law or in equity, and whether it is for the plaintiff or the defendant; and it is equally binding though a suit between the same parties with the same subject-matter was pending in the other State, and even if proceedings were first begun there (*Paine v. Ins. Co.*, 11 Rhode Island 411); nor do mistake of law or of fact or irregularity of local practice in the foreign court affect the binding nature of a judgment. It is often said that a foreign judgment may be impeached for fraud, and indeed it may usually, like a domestic judgment, be so impeached in equity; but by the better view it cannot be so impeached at law, though this doctrine is sometimes referred to the Constitution and confined to inter-State judgments (*Christmas v. Russell*, 5 Wallace [U.S.] 290; Gray, J., in *Hilton v. Guyot*, 159 U.S. 113). The judgment must be for a sum of money of ascertained amount; if the amount is uncertain the judgment cannot be enforced; but it may be for an amount payable from time to time, like a decree for alimony, and

it will then be enforced as to all overdue payments (*Lynde v. Lynde*, 181 U.S. 183).

A judgment for the doing of an act, except the mere payment of money, is not directly enforceable in another court, even of the same State. It is therefore impossible to enforce a foreign decree that an act be done by the defendant, such as making a conveyance, either by decreeing the conveyance without judicial investigation or by regarding it as made (*Bullock v. Bullock*, 52 New Jersey Equity 561).

Administration.—Estates administered by a court are administered in accord with the law of the State where the administration is had. Each State may administer such things only as are within its jurisdiction; so that in the case of an estate part of which is found in each of two or more States administration must generally be undertaken independently in each State. In the case of administration of the estate of a deceased, the executor or administrator gets power to collect claims owing to the deceased from, and is obliged to pay claims against the deceased by, the statutes of the State of his appointment; and he can neither sue nor be sued on such a claim in another State (*Johnson v. Powers*, 139 U.S. 156). In cases, however, where no domestic administrator has been appointed and there are no local creditors to be prejudiced, a foreign administrator may collect claims due the deceased (*Wilkins v. Ellett*, 108 U.S. 256).

Recognition and Enforcement of Foreign Rights.—A right having been created by the appropriate law, the recognition of its existence follows everywhere (Folger, J., in *King v. Sarria*, 69 New York 24). So a body created as a corporation in one State will be recognized as such in another State (*Bank of Augusta v. Earle*, 13 Peters [U.S.] 519). This is true even though the right so created is absolutely illegal in the State which recognizes it. Thus, a polygamous or incestuous marriage contracted in a State where it is valid will be recognized as a legal status of that kind even in a State where it is illegal (*Sutton v. Warren*, 10 Metcalf [Mass.] 451); though it need not be treated as a so-called "Christian" marriage would be. It is merely recognizing a foreign fact. A slave for the same reason must be recognized as such even in a free State. It is true that if a slave comes into a free State he cannot be restrained by his master; not because he ceases to be a slave, but because in such a State there is no right in a master to restrain a slave (Ware, J., in *Polydore v. Prince*, Ware [U.S. district court] 402).

Though a foreign right will always be recognized as existing, it does not follow that it will be given any legal force. No foreign right will be enforced unless the law of the State so provides. Where a right has once been created by the proper law it will be enforced in another State even where it would not originally have been created by that State on the same facts (*Greenwood v. Curtis*, 6 Massachusetts 358), but enforcement of a foreign right will be denied where it would be illegal to carry it out, as where the right was created in evasion or fraud of the domestic law (*Hill v. Spear*, 50 New Hampshire 253), or against public policy or morality (*Emory v. Burbank*, 163 Massachusetts 326). So where a foreign marriage is valid and the spouses come into a State where it is regarded as incestuous they may not cohabit as man and wife in that State (*State v. Brown*, 47 Ohio 102).

No governmental right of another State will be enforced, like a right to taxes or a claim for a criminal fine; and for the same reason an alimentation claim created to save the State from the burden of support of a dependent person will not be enforced in another State.

Remedy.—The remedy afforded for the enforcement of a foreign right is such only as a State may choose to allow. The State may open its courts to whom it pleases; but foreigners are usually allowed free access to courts (*Roberts v. Knights*, 7 Allen [Mass.] 449). No action can be brought if it may bring into question the title to foreign land; nor can a foreign right be enforced which requires for its proper enforcement a procedure which the court of forum cannot provide.

Where suit is brought in a foreign court, all matters relating merely to the remedy are determined by the law of the forum.

Thus the law of the forum determined the proper parties, the proper form of action (*LeRoy v. Beard*, 8 How. [U.S.] 451), the exemptions from attachment (*Mineral Point R.R. v. Barron*, 83 Illinois 365), the right to set-off (*Gibbs v. Howard*, 2 New Hampshire 296), the right to confess judgment (*Hamilton v. Schoenberger*, 49 Iowa 385). The law of the forum determines whether action is barred for usury (*Gale v. Eastman*, 7 Metcalf [Mass.] 14) or for failure to comply with the statute of frauds, where usury or the statute of frauds goes rather to the remedy than to the right. If it is claimed that remedy is barred by the statute of limitations, it is the statute of the forum which decides (*Townsend v. Jemison*, 9 How. [U.S.] 407), unless indeed some statute which has power to do so has actually extinguished the right. That may happen where it was a condition of the right at the time of its creation that it should be exercised within a certain time (*The Harrisburg*, 119 U.S. 199).

The rules of evidence applied are those of the forum; and so presumptions of fact are determined by the law of the forum (*Hoadley v. Transportation Co.*, 115 Massachusetts 304). The measure of damages, since it has to do with the nature of the right of action, must be determined by the law of the State where the action arose; it is not a question of remedy (Paynter, J., in *R.R. v. Whitlow*, 105 Kentucky 1; see *Meyer v. Estes*, 164 Massachusetts 457). So interest, where given by way of damages, is regulated by the law of the place of payment, not of the forum (*Peck v. Mayo*, 14 Vermont 33; *Healy v. Gorman*, 15 New Jersey 328; *contra*, *Ayer v. Tilden*, 15 Gray [Mass.] 178).

Where, however, a statutory regulation of damages amounts not to a settlement of the rules for measuring compensation but to a limitation (irrespective of the amount of damage) of the amount allowed to be recovered, it has to do with remedy rather than with right, and is governed by the law of the forum (Finch, J., in *Wooden v. R.R.*, 126 New York 10; compare *R.R. v. Babcock*, 154 U.S. 190).

BIBLIOGRAPHY.—The classical treatise is J. Story, *Conflict of Laws* (1st ed. 1834); the latest and most trustworthy is H. F. Goodrich, *Conflict of Laws* (1928). See also "Restatement of the Conflict of Laws," (J. H. Be.)

INTERNATIONAL LAW, PUBLIC, the general term for the law governing the relations and intercourse of States *inter se*. The parties are States and not nations, so that the word "international" does not accurately define the scope of the subject. Nor do authors always confine themselves to its proper limitation. Thus the rules relating to nationality and naturalization, extradition, patents, trade marks, etc., which affect States on the one side and foreign persons on the other, are generally included among the subject-matter of international law. There is a special branch of international law, known as Private International Law (see **INTERNATIONAL LAW, PRIVATE**), which deals exclusively with the relations of persons belonging to different States, in which States as such are not parties.

The term "international" was first used by Bentham, who observed:—

"The word *international*, it must be acknowledged, is a new one; though, it is hoped, sufficiently analogous and intelligible. It is calculated to express in a more significant way the branch of law which goes commonly under the name of 'law of nations,' an appellation so uncharacteristic that, were it not for the force of custom, it would seem rather to refer to internal jurisprudence. The chancellor d'Aguesseau has already made, I find, a similar remark; he says that what is commonly called *droit des gens* ought rather to be termed *droit entre les gens*." (Introduction to the *Principles of Morals and Legislation*.) But Franciscus and Victoria had already in the 16th century used the Latin form *jus inter gentes*.

There has been much controversy as to the aptness of the use of the word "law" in this connection. "Strictly speaking," observed Lord Chief Justice Coleridge in his judgment on the *Franconia* case (*R. v. Keyn*, 2, Ex. D. 63), "international law is an inexact expression, and it is apt to mislead if its inexactness is not kept in mind. Law implies a lawgiver and a tribunal capable of enforcing it and coercing its transgressors, but there is no common

lawgiver to sovereign States, and no tribunal has the power to bind them by decrees or coerce them if they transgress. The law of nations is that collection of usages which civilized States have agreed to observe in their dealings with one another. What these usages are, whether a particular one has or has not been agreed to, must be matter of evidence. Treaties and acts of States are but evidence of the agreement of nations, and do not, in England at least, *per se* bind the tribunals. Neither certainly does a consensus of jurists, but it is evidence of the agreement of nations on international points, and on such points, when they arise, the English courts give effect as part of English law to such agreement." Sir James Stephen took a similar view.

This was declared by Lord Russell of Killowen to be based upon Austin's definition, which was too narrow and relied too much on force as the governing idea. "If," he added, "the development of law is historically considered it will be found to exclude that body of customary law which in early stages of society precedes law, which assumes definitely the character of positive command coupled with punitive sanctions. But even in societies in which machinery exists for the making of law in the Austinian sense, rules or customs grow up which are laws in a very real sense of the word, as for example the law merchant. Under later developments of arbitrary power, laws may be regarded as the command of a superior with a coercive power in Austin's sense: '*Quod placuit principi, legis vigorem habet*.' In stages later still, as government becomes more frankly democratic, resting broadly on the popular will, laws bear less and less the character of commands imposed by a coercive authority, and acquire more and more the character of customary law founded on consent. . . . I claim, then, that the aggregate of the rules to which nations have agreed to conform in their conduct towards one another are properly to be designated international law." (Address at Saratoga Springs [N.Y.]; see *Law Quarterly Review*, p. 311, 1896.) This recalls Blackstone's definition: "The law of nations is a system of rules, deducible by natural reason, and established by universal consent among the civilized inhabitants of the world, in order to decide all disputes, to regulate all ceremonies and civilities, and to ensure the observance of justice and good faith in that intercourse which must frequently occur between two or more independent States, and the individuals belonging to each." (*Commentaries on the Law of England*, 4th ed., iv. 66.) The current English narrower view owes its origin chiefly to the influence of John Austin, and the current broader one to that of Sir Henry Maine. The increasing popularity of references to international arbitration (see **ARBITRATION, INTERNATIONAL**), the adoption of a large number of special treaties making such references compulsory in certain cases, the establishment of an increasing recourse to the court for the decision of difficulties between States created by The Hague "Convention for the pacific settlement of disputes between States" of 1899 (see **PEACE**), the adoption of fixed rules of law in the international conventions in 1899 and 1907 dealing with many of the most controversial questions of international usage, and the creation of the League of Nations and its Permanent Court of International Justice (*q.v.*), have so transformed the subject that if, as Lord Coleridge said, law implies a law-giver and a tribunal capable of enforcing it, these conditions are now, at any rate, partly fulfilled. We shall see below to what extent it may be necessary to regard power of enforcement against transgressors as requisite to give international law the character of law properly so-called.

Sanctions.—The subject of the enforcement of international law, or its "sanctions," has given rise to much controversy. The word "sanction" is derived from the Lat. *sanctio*, which in turn is derived from *sancire*, to consecrate. In its original sense *sanctio* means consecration. From this followed the sense of religious obligation. Thus *sancire legem* is used by Roman writers as meaning that observance was made obligatory, but without reference to the idea of there being a remedy or penalty for non-observance.

Bentham, who worked out the theory of legal sanctions as applied to modern law, describes them as equivalent to pleasures and pains derived from four different sources. These are physical, political, moral and religious.

Austin's analysis of this vague subdivision led him to a more precise determination of the relationship of sanctions to law, viz., that a law properly so-called is a command and its sanction is the power to enforce obedience to it. Stated briefly, any other kind of law according to Austin is not positive law but merely called so by analogy. Applying this test to international law he concludes that the law obtaining between nations is not positive law; for every positive law is set by a given sovereign to a person or persons in a state of subjection to its author. The law obtaining between nations is only law set by general opinion with duties which are only enforced by moral sanction, by fear on the part of nations, or by fear on the part of a sovereign, of provoking general hostility, and incurring its probable evils, in case they should violate maxims generally respected. (*Province of Jurisprudence determined*, 2nd ed., 1861, p. 177; Austin explains his view more fully at p. 127.)

Sir H. Maine's somewhat indirect answer to Austin may now be taken as the view held at least by British theoretical writers. "Austin," he said, "has shown, though not without some straining of language, that the sanction is found everywhere, in positive law, civil and criminal. This is, in fact, the great feat which he performed, but some of his disciples seem to me to draw the inference from his language that men always obey rules from fear of punishment. As a matter of fact this is quite untrue, for the largest number of rules which men obey are obeyed unconsciously, from a mere habit of mind. Men do sometimes obey rules for fear of the punishment which will be inflicted if they are violated, but compared with the mass of men in each community, this class is but small; probably it is substantially confined to what are called the criminal classes, and for one man who refrains from stealing or murdering because he fears the penalty there must be hundreds of thousands who refrain without a thought on the subject." (*International Law*, p. 50.)

The view, however, that a law is not devoid of binding character because there is no authority to enforce its observance hardly requires justification at the present day. The fact that any well-established international usage is observed, and that States invariably endeavour to answer any reproach of departing from such usage by explanations showing that the incriminated act is justified by recognized rules of international law, is evidence of its binding character. As the late Prof. Rivier, one of the leading authorities on Roman law, as well as an international jurist of eminence, has expressed it: "The law of nations is positive law because States wish it to be so. They recognize its compulsory character and proclaim it. As they are their own legislators and make their common laws by express or tacit consent, they attest explicitly and implicitly their conviction that its principles are binding upon them, as judicial principles, as law. Innumerable public acts, affirmations, declarations and conventions are there to prove it. On the other hand, never in any published official act of the present age, verbal or written, has a State dared to declare that it did not consider itself bound by the law of nations and its principles." (*Droit des gens*, 1896, i. 22.) With this we may compare Savigny's words: "A community of judicial conscience can be formed among nations like that which positive law creates in the bosom of one people. The foundations of that intellectual community are constituted partly by a community of race, partly and especially, by a community of religious convictions. Such is the basis of the law of nations which exists principally among European Christian States. . . . We are entitled to look upon this law as a positive law, although it is an incomplete judicial formation." (*System des heutigen, römischen Rechts*, 1840, i., s. 11.) States, as Prof. Rivier says, have again and again solemnly declared their determination to abide by the principles of international law. Witness the Declaration of Aix-la-Chapelle of Nov. 15, 1818, in which the representatives of five Powers, Austria, France, Great Britain, Russia and Prussia, solemnly stated that "the sovereigns in forming this august union have regarded as its fundamental basis their unchangeable resolution never to depart, either amongst themselves or in their relations with other States, from the strictest observance of the principles of the law of nations, principles which, in their application

to a permanent state of peace, can alone effectively guarantee the independence of each government and the stability of the general association." In the negotiations for the Treaty of London concerning the Black sea (Mar. 13, 1871), at which seven Powers were represented, Austria-Hungary, France, Germany, Great Britain, Italy, Russia and Turkey, a resolution on the sanctity of treaties was annexed to the first protocol, stating that the plenipotentiaries recognize that it is an essential principle of the law of nations that "no Power can liberate itself from the engagements of a treaty, nor modify the stipulations thereof, unless with the consent of the contracting powers by means of an amicable arrangement." Even in 1908, when Austria-Hungary proceeded to the annexation of Bosnia-Hercegovina without obtaining the prior assent of the high contracting Powers, who under the Treaty of Berlin of 1878 had granted her temporary occupation of the annexed provinces, the protests of the Powers concerned were answered by Austria-Hungary declaring that she had done nothing contrary to the law of nations or affecting the sanctity of treaties, because the Powers had given their tacit consent to the practical transformation of her temporary into a permanent occupation.

The public opinion of the civilized world, in fact, plays in an ever-increasing degree the part of a sanctioning authority. With the growth of international intercourse and international interdependence the danger of isolation or of discredit or even of "boycotting" becomes a matter of increasing importance in the conduct of States. The national press and periodical literature, with exceptions no doubt, are among the chief factors in the development of this public opinion, but it is by no means dependent upon them. Personal intercourse among citizens of the same country, and between statesmen, politicians and citizens of different countries has a still greater effect in the creation of the mental attitude of nations towards each other. This exposes any departure from recognized usage or any disregard for international obligations to such reprobation throughout the whole world, that, far from taking advantage of the absence of any coercive method of enforcing obedience to the principles of international law, States compete with each other in asserting their strict fidelity to such principles. And now successive diplomatic conferences have codified many of the chief branches of international usage, thus diminishing the possible cases in which States can take advantage of the uncertainty of the law and, by quibbling over its interpretation, escape from its obligations.

Sources and Foundations.—It is usual, following Wheaton's classification (*Elements*, 1885, pp. 22 *et seq.*), to enumerate the sources of international law in the following groups: text-writers of authority as witnesses of usage; treaties of peace, alliance and commerce; ordinances of particular States, prescribing rules for the conduct of their commissioned cruisers and prize tribunals; adjudications of international tribunals; written opinions of official jurists given confidentially to their own government; history of wars, negotiations, treaties and other transactions relating to the public intercourse of nations. It is in these different classes of opinions and precedents that writers have been in the habit of searching for those arguments and analogies on which have been built up the system and principles called international law.

Wheaton, it is seen, regarded text-writers as witnesses of the usage of nations. He explains his meaning as follows: "Without wishing to exaggerate the importance of these writers, or to substitute in any case their authority for the principles of reason, it may be affirmed that they are generally impartial in their judgment. They are witnesses of the sentiments and usages of civilized nations, and the weight of their testimony increases every time that their authority is invoked by statesmen, and every year that passes without the rules laid down in their works being impugned by the avowal of contrary principles." This distinguished writer's quasi-explanation of the sources of international law is extremely vague. He masses together cause and effect, private and public opinions, usage and exceptions. Oppenheim has endeavoured to give a more scientific explanation of the growth and development of international law, and objects to calling sources of international law what are mere factors influencing its growth:—

"... Custom and treaties," he observes, "are the two exclusive sources of the law of nations. When writers on international law frequently enumerate other sources besides custom and treaties, they confound the term 'source' with that of 'cause' by calling sources of international law such factors as influence the gradual growth of new rules of international law without, however, being the historical facts out of which these rules receive their legal force. Important factors of this kind are: Opinions of famous writers on international law, decisions of prize courts, arbitral awards, instructions issued by the different States for the guidance of their diplomatic and other organs, State papers concerning foreign politics, certain municipal laws, decisions of municipal courts. All these and other factors may influence the growth of international law either by creating usages which gradually turn into custom, or by inducing the members of the family of nations to conclude such treaties as stipulate legal rules for future international conduct."

"A factor of the special kind which also influences the growth of international law is the so-called comity (*Comitas gentium*, *Convenance et courtoisie internationale*, *Staatenkunst*). In their intercourse with one another States do observe not only legally binding rules and such rules as have the character of usages, but also rules of politeness, convenience and good-will. Such rules of international conduct are no rules of law, but of comity. The comity of nations is certainly not a source of international law, as it is distinctly the contrast to the law of nations. But there can be no doubt that many a rule which formerly was a rule of international comity only is nowadays a rule of international law. And it is certainly to be expected that this development will go on in future also, and that thereby many a rule of present international comity will in future become one of International Law." (*International Law*, 1905, s. 19.)

Precedents.—We prefer to regard international law as deriving the rules composing it from practically the same sources as domestic law, and to attribute to text-writers more or less the same value in its development as in that of the private law of nations. The same primary rules of conduct are appealed to between States as between individuals, and precedents play exactly the same part wherever human actions are concerned. In both cases what has been done before commends itself when the responsibility of taking steps pledging the future is concerned. Statesmen on whom great responsibility impends, on whom the conduct of momentous negotiations has devolved, and who will have to render an account of their work to the sovereign or nation they represent, preserve an argument in their own favour in departing as little as possible from any course taken in previous similar circumstances. Precedents, moreover, are arguments for acceptance by their adversaries or counter-negotiators. In fact, in diplomacy even more than in matters of domestic government precedents play a dominant part in the growth of usage. These precedents are often in themselves originally local usages, such as grew up in the intercourse of the Italian communities. Italy, in fact, served as a laboratory for early diplomatists and writers. It was in the intercourse of these active and ambitious States that grew up the very notion of a foreign diplomacy and the necessity of rules of conduct in this miniature Europe, with its perpetual antagonisms and jealousies, its balance of power, its idea of a State distinct from a nation and of a community of States elbowing each other in their daily contact. It was there that grew up the institution of passports, the distinction between armed forces and civilians, international comity, and in fact the very notion that States have an interest in the observance of law and order among them. In the same way the active commercial intercourse in the Mediterranean led, in the common interest, to the development of rules of the sea in time of peace, and later to others in time of war.

In the north of Europe, again, out of the active commercial intercourse among the Baltic and North sea communities grew rules of the sea in the same common interest. It was the Thirty Years' War, with its revolting cruelty, which brought out the contrast between the more humane practice of war as an art in Italy and the mere bludgeonry which prevailed in the brutal struggle which

disgraced the first half of the 17th century. The brutality of the struggle turned thinkers' attention to the need of formulating rules for the protection in time of war of non-combatants and the innocent subjects of absolute sovereigns, the treatment of the sick and wounded, the prohibition of wanton pillage and the other horrors which shocked the awakening conscience of northern Europe. It was the starting-point of the age of text-books.

Authoritative Text-writers.—The first effective work, the one which was the first to influence sovereigns and statesmen, was Grotius's *De jure belli ac pacis* (Paris, 1625), which practically exhausted the theoretical arguments in favour of the new subject. Nobody has in fact since brought to light any new conception of the foundations of international law. An exhaustive and masterly treatise having been published, no further subsequent treatise was necessary to show what all men were beginning to feel. He sublimated the feelings of his age, and having arrived at the pure substance, the work of proving the need of his subject was disposed of for all time. Pufendorf (1632–97), who, in the sequence of effective text-writers, succeeded Grotius, endeavoured to base international law on an ethical basis accepted by all peoples without necessity for a common creed or standard of morals, but it is doubtful, whatever may have been the extent to which he stimulated the study of jurisprudence, whether he did much in advancing the practical development of the law of nations. His book *De jure naturae et gentium* (1672), as its name indicates, based international law on what he called the law of nature, a subject which has much exercised the minds of jurists searching for an ethical basis for existing law.

The scientific mind of Leibnitz (1646–1716) revolted against this theoretical and doctrinaire tendency of Pufendorf and other writers, who were following with feeble tread in the giant footsteps of Grotius. He saw that the practice of nations was taking a course dictated by the current moral standards of civilized society, and that the philosophizing of the text-book writers was leading them away from that actual practice which they should use as data for their conclusions. Natural science, moreover, had taught him the risk of theorizing on imperfect data, and while writing a history of Brunswick it occurred to him that treaties and diplomatic documents generally were the substances and tests of the publicist's laboratory. His *Codex juris gentium diplomaticus* (1693–1700) gave a more precise direction to speculations on the subject.

The next great writer of authority united all the qualities of a practical lawyer and jurist. This was Bynkershoek (1673–1743). He was the first writer on international law who dealt with public maritime law as a matter demanding special treatment and involving a set of principles not called into action in territorial warfare. A magistrate administering the law in a great commercial country, whose interests were on or across the high seas rather than within the narrow European limits of Holland, Bynkershoek, like Leibnitz, searched for his data in the actual practice of nations in their intercourse with one another. He applied his clear, legally trained mind to deriving principles from practice instead of endeavouring to build up a practice on abstract principles. It was he who first generalized the different isolated usages which had grown up at different spots in northern Europe in the interest of maritime defence, and evolved from practice the principle that dominion seawards was limited to the extent to which it was possible to enforce it (cannon-shot range), a principle which not only created the legal institution of territorial waters, but has since been imported into other branches of international law, and has indirectly influenced the suppression of fictitious blockades and fictitious occupations of territory.

A contemporary of Bynkershoek was Christian de Wolff (1679–1754), a philosopher, mathematician, theologian, lawyer and disciple of Leibnitz. Wolff's great work on the *Institutions of the Law of Nature and Nations* is a learned and accurate treatise drawn from all the well-known sources of knowledge, and, just as Grotius based his demonstrations on the then imperfect knowledge of public events of his time, Wolff based his on the more accurate sources of information which had grown up under the influence of Leibnitz, and created a connected system out of the

scattered fragments available. But his book was written in Latin at a period when scholarship had declined, and its influence was only felt after Vattel (1714-67) wrote his *Droit des gens, ou principes de la loi naturelle appliquées à la conduite et aux affaires des nations et des souverains* (1758). His book had all the charm, although Vattel was a Neuchâtelais, of the French writers of his time, and he it was who popularized the study of international law. His book was based chiefly on the work of Wolff; in it he gave what was best amongst his predecessors without attempting to add anything original of his own. It became the handbook of statesmen and jurists, and has never ceased to be quoted by them down to the present day.

But the opinions of jurists in international law can have little more than the value of criticism and co-ordination. They have seldom served to make law, though they have the weight of all statements made by those who have made a special study of any branch of law, as to what they had gathered to be the existing practice at the time when they wrote, or as to the trend which they showed that practice might be taking. Great lawyers and writers like those we have mentioned, and such as Lord Mansfield, Sir William Scott, Chief Justice Marshall and others, have done the work of classifying facts, deducing conclusions from them and connecting rules with psychological and ethical motives, and have thus sent a current of higher intelligence through the subject which has raised it to its present methodical form. Still international law remained a wide field for controversy. Authors were agreed on general principles, but when these general principles were applied in practice, the shortcomings of unwritten usage often caused as much difficulty as that which the appeal to principles was intended to overcome.

Hague and London Conferences.—What may be called the first enactment of rules of international law was the Declaration of Paris of 1856 (*q.v.*), but the great work of codification, or rather of reducing into writing the rules which had been floating as an unwritten law in the conscience of Europe, was undertaken by The Hague Conferences, which may be said to be and to have created an entirely new factor in the domain of international law. Two of the conventions adopted in 1899 completed work which had already been commenced long before, viz., those on the usages of war and on the adaptation of the Geneva Convention to naval war. The third established methods for the pacific settlement of international difficulties, including the formation of The Hague Court of Arbitration. Recourse to the latter was purely optional, but the other two conventions have been absorbed into the national law of the ratifying countries, and thus have also the domestic sanction States give to their own laws. The work of the Conference of 1907 was of a much wider and more exhaustive character than that of 1899. It comprised, besides revised conventions on the matters dealt with in 1899, new conventions on the following subjects: Opening of hostilities; position in naval war of enemy's merchant ships at beginning of hostilities; conversion of merchant vessels into warships; rights and duties of neutral States in naval war; the laying of automatic submarine contact mines; the bombardment of undefended places by naval forces; treatment of fishing vessels, postal correspondence and capture generally in maritime war; and recovery by force of contract debts. It also adopted a convention for the creation of an International Prize Court of Appeal, which led to the calling of a fresh conference on prize law. This conference sat in London from Dec. 4, 1908, to Feb. 26, 1909, and was confined to representatives of the following countries: Great Britain, France, Germany, United States of America, Italy, Austria-Hungary, Russia, Japan, Holland and Spain. It adopted a series of rules on naval warfare relating to blockade in time of war; contraband of war; unneutral service; destruction of neutral prizes; transfer to neutral flag; enemy character; convoy; and resistance to search and compensation.

Standard of Right Conduct.—Underlying the details of both the new international legislature and the new international judicature are certain principles which may some day have to be officially defined. These principles have necessarily fluctuated with the standard of morals of each period. With the contem-

porary development of the public conscience, they are undergoing changes and a betterment which it is not desirable to check by yet nailing them up as immutable articles of faith. Till quite recently it was usual to speak of the common standard of right conduct prevailing throughout the Christian world, a standard to which responsible statesmen tried to adjust their direction of the affairs of State. The admission of Japan into the councils of the Great Powers has introduced a non-Christian element whose standard of conduct was not identical with nor based upon Christian morals. Turkey, though admitted in 1856 to European councils, remained rather the occasion of their deliberations than a deliberating party. Her new position as a constitutional State, with a code of morals at any rate in some essentials distinct from that of Christian peoples, will add a further new non-Christian element into the moral foundations of international conduct. The influence of western Europe, however, in both Japan and Turkey, has hitherto in all external development been paramount. Japan, after examining all the existing systems, has even adopted the best she found in Western morals, and in her schools inculcates Christian ethics as a subject *per se* without reference to Divine revelation or authority. Turkey, too, has the advantage of possessing a code of morals which produces so high a standard of right conduct in private life that very little in the way of moral lessons will have to be learned by the Ottomans from Western civilization. As regards practice, it is unreasonable to expect that the high estimate of the moral standard of west European civilization, which is cherished by those who profess its principles, should be accepted by other peoples with unqualified assent.

The very notion of the "right of conquest," and that the victorious are entitled to an indemnity without reference to any question of right and wrong or of justice and injustice, shows that there are principles in actual practice which lie outside and have no analogy in the principles of private law. In the partition of Africa, native States have been treated as non-existent except as local bodies. They have been annexed to European States without reference to their will or consent. Treaties have indeed been made with them, but they have rather been regarded as evidence of prior occupation than as involving any question of native right. The test in the distinction between civilized and uncivilized States which is regarded as warranting exclusion from enjoyment of the right to consideration as independent States, and admission to the community of the civilized world, is in practice the possession of a regular government sufficient to ensure to Europeans who settle among them safety of life and property. Every country, in principle, possessing such a government has *prima facie* the rank of a State and is entitled to treatment as a civilized community. Treaties made with it for the purpose of extra-territorial jurisdiction are intended merely to take into account a difference of judicial institutions but are not supposed to detract otherwise from the possession of such equality and independence. This principle has no analogy in private morals, and has been, slight as it is, more honoured in the breach than the observance. If indifference to native right has provoked reaction, it has been on the part rather of philanthropists than of statesmen. Their movement for the protection of African aborigines has, however, resulted in at least one great international charter for the prevention of the further degradation of African aborigines, viz., the General Act of Brussels of 1885. A vigorous outcry has also been raised against the methods of the Government of the Congo State. But the agitation ought not to be confined to this part of Central Africa. Other Governments are also in fault. In fact, the contact of the European with Central Africa has, throughout, with few exceptions, been one of barbarous practice quite inconsistent with the principles which Christian missionaries have been sent to teach the African native.

European enterprise in Asia has had still less justification. The action taken for the repression of the "Boxer" movement in China, like previous European incursions, had no essential characteristic distinguishing it from the incursions of the Northmen. The Japanese took part in the "Boxer" expedition, and the example of respect for native right and of orderly self-restraint they set has been universally acknowledged. But the lesson is one of

greater significance than one of comparative ethics. The rise of the power of Japan and her obvious determination to constitute herself the champion of the races of eastern Asia has widened the scope of international law, and we may now regard China as henceforth under the protection of the same principles as European States.

Fundamental Principles.—The three chief principles of inter-State intercourse, those, in fact, on which international law is based are:—

1. Recognition of each other's existence and integrity as States.
2. Recognition of each other's independence.
3. Recognition of equality, one with another, of all independent States.

As regards the first of these principles *see* STATE. From the principle of independence it follows that every State has a right to change its form of government and to enjoy the free exercise of its internal energies. This is subject only to the limitation that in the exercise of this right other States or their subjects shall not be molested or otherwise suffer. The equality of all independent States entitles them to respect by other States of all the forms of ceremonial and to the same treatment by others, where their interests are identical, whether they are strong or weak. This principle has often been violated, but it is, nevertheless, acknowledged wherever possible, as in diplomatic conferences relating to all matters of an economic, hygienic, industrial or social character. Even at the Conference of Algieras, though the Powers immediately concerned from a political point of view were only Great Britain, France, Germany and Spain, the following were also represented as having economic interests in Morocco, viz., Austria-Hungary, Italy, Russia, Belgium, Holland, Portugal and Sweden.

Ships on the high sea being regarded as detached portions of the national territory, there is also the derived principle of the freedom of the high sea, of the independence and equality upon it of the ships of all nations subject only to due respect being paid to the independence and equality of all others and to such conventional restrictions as States may impose upon themselves (*see* TERRITORIAL WATERS). This principle is re-enunciated in the preamble to the Convention of 1907 on the laying of automatic submarine contact mines (*see* PEACE CONFERENCES).

The Hague Conventions are based on these principles, to which there is a tendency to add another, viz., the right to arbitration in certain cases. This principle is set out more or less tentatively, it is true, but it is being completed by separate treaties of compulsory arbitration in connection with the cases referred to. It is enunciated in the following article of the Convention of 1907 for the pacific settlement of international disputes:—

"In questions of a legal nature, and especially in the interpretation or application of international conventions, arbitration is recognized by the contracting Powers as the most effective, and, at the same time, the most equitable means of arranging disputes which diplomacy has failed to settle. Consequently, it is desirable that, in disputes regarding the above-mentioned questions, the contracting Powers should, if need be, have recourse to arbitration, in so far as circumstances permit." (Art. 28.)

The principle of arbitration has also been adopted in reference to the recovery of contract debts under the following article of the "Convention respecting the limitation of the employment of force for the recovery of contract debts":—

"The contracting Powers agree not to have recourse to armed force for the recovery of contract debts claimed from the Government of one country by the Government of another country as being due to its subjects or citizens. This undertaking is, however, not applicable when the debtor State refuses or neglects to reply to an offer of arbitration, or, after accepting the offer, renders the settlement of the *compromis* impossible, or, after the arbitration, fails to comply with the award." (Art. 1.)

The codification of international law itself, begun at The Hague and London Conferences, is an admission of the binding character of the primary principles set out above.

One of the chief tendencies of contemporary reform is also to

restrict the effect of fictions and reduce rights to the limits of their practical application. Between two alternatives, the one to assert rights which cannot possibly be maintained by force such as claims to dominion over portions of the high sea (*see* HIGH SEA, WATERS, TERRITORIAL), "paper blockades" (*see* BLOCKADE) and fictitious occupations of territory (*see* OCCUPATION), and the other to require actual physical assertion, a medium course is growing up, viz., that of recognizing potential assertion, i.e., assertion limited to physical possibilities. With the aid of the Institute of International Law, the International Law Association and other reforming agencies (*see* PEACE), expert opinion in these matters is becoming homogeneous throughout the civilized world, and the ground is being prepared for a clearer understanding of these fundamental principles by the statesmen and State officials who have to apply them in practice.

The outstanding developments in international law since the World War are so distinctive that it has been considered expedient to deal with them under separate headings, rather than to attempt to present them in any one general article. The attention of the student is especially drawn to the following articles: ARBITRATION, INTERNATIONAL; BLOCKADE; CONTRABAND; CONVOY; COVENANT; INLAND WATER TRANSPORT; LABOUR LAWS; LEAGUE OF NATIONS; MANDATES; MIGRATION; MINORITIES; NEUTRALITY; PERMANENT COURT OF INTERNATIONAL JUSTICE; PRIZE AND PRIZE COURTS; SANCTIONS AND GUARANTEES; TREATIES; VISIT AND SEARCH; WAR, LAWS OF; WASHINGTON CONFERENCE. (T. B.)

INTERNATIONAL MERCANTILE MARINE COMPANY, a corporation engaged in the transportation of passengers, mails, live stock, merchandise, and other goods between various parts of the world, was incorporated June 6, 1893, under the laws of New Jersey, as the International Navigation Company, with a perpetual charter, which provides also for the "purchasing, owning and holding of stocks, bonds and other securities." On Oct. 1, 1902, the charter was amended, capital raised to \$120,000,000, and the White Star, Leyland, Atlantic Transport and Dominion lines were acquired, and the name of company changed to International Mercantile Marine Company. On Jan. 1, 1928, the steamship lines owned by the company were the American, Red Star, Atlantic Transport, Leyland and Panama Pacific, as well as a 5% interest in the Holland-America line; and it also owned the Number One Broadway Corporation, New York city, in which is vested ownership of the building at that address. International Mercantile Marine Company formerly owned the White Star line also, but on Jan. 1, 1927, it sold for £7,000,000 the entire business and fleet to the Royal Mail Steam Packet Company. At the time of this transaction, an arrangement was made whereby the International Mercantile Marine Company agreed to act as agent for the White Star line, in the United States and Canada, for at least two years from the date of the sale. On Dec. 31, 1926 (before that sale had been effected), the Company's fleet comprised 100 ships, whose gross aggregate tonnage was approximately 1,091,000; Jan. 1, 1928, the total number of ships was 53, with aggregate tonnage of about 465,000. The organization owns terminal property and an office building in Antwerp and has terminal arrangements at London, Southampton, Liverpool, Montreal, New Orleans, Philadelphia, Boston and other ports; a leasehold, until 1933, of Oceanic House, an office building in London; and a lease until 1940 of five piers on the Hudson river, New York city. Sailings of the International Mercantile Marine Company and its subsidiaries cover some 40 services, which include most of the principal ports on the eastern coast and the Gulf of Mexico (U.S.A.) as well as Los Angeles and San Francisco; the leading European and English shipping points; and Mexico, Central America and the West Indies. For the ten years 1917-26, inclusive, the aggregate consolidated net income was \$34,016,000, after depreciation. As of Dec. 31, 1926, the net working capital was \$17,903,000 (or about 25% more than on Dec. 31, 1925); total current assets were \$35,215,000, more than twice the amount of current liabilities (\$17,311,280); net income of the parent company, \$906,000; total surplus, \$17,147,069; total assets, \$216,060,308; capital

stock, authorized and issued, consisted of \$60,000,000 each of \$100 par common and 6% cumulative preferred, of which the company held in its treasury \$10,128,200 common, and \$3,275,000 preferred. The company's principal office is in New York city.

(P. A. S. F.)

INTERNATIONAL NEWS SERVICE. This news service was organized in 1906 by William Randolph Hearst. It is a profit-making corporation, as distinguished from the mutual news association, and its function is to serve evening and Sunday newspapers with the latest news from all parts of the world. Several hundred newspapers, in the United States and other countries, subscribe either for the full daily report, which is transmitted over leased telegraph lines, or for limited reports confined to a daily word ration or to a class of news interest, such as sports. The Universal Service, an auxiliary, supplies subscribing morning and Sunday newspapers with special or "feature" news. The headquarters are in New York city.

(M. E. P.)

INTERNATIONAL PAYMENTS. The observer who learns that, during a given year, England imported £100,000,000 worth of raw cotton from the United States, and sold £50,000,000 worth of coal to the Continent, and that simultaneously Austria, Hungary, Finland and other countries raised loans totalling \$200,000,000 in New York, can be excused for wondering exactly how these huge sums of money are remitted. Even if he is conversant with the theory of the balance of trade (*q.v.*), or has learnt that "imports pay for exports," and even if he knows something of the principles of Foreign Exchange (*q.v.*), he may still be excused for a failure to realize how it works out in actual practice.

In reality the process of remittance from country to country is extremely simple, and the chief stumbling blocks are the existence of different currencies, the huge sums involved and the use of technical terms by those engaged in the business. The easiest way to approach the question is by the examination of the normal financial relations between individual and individual.

Take the case of: (1) Brown, a butcher, who banks at bank A; (2) Jones, a farmer, who banks at bank B; (3) Smith, a needy relative of Jones, who banks at bank C.

Brown buys cattle from Jones and in due course owes him £50. Smith buys meat from Brown, also to the tune of £50. Finally Smith goes to Jones and borrows £50. In each case, to settle the amounts outstanding, the payer, whether he be debtor or lender, draws a cheque for £50 in favour of the payee, whether he be creditor or borrower. The cheque is drawn on the drawer's bank, and paid by the payee into his own bank.

The result is that bank B holds a cheque for £50 drawn by Brown on bank A and relating to his purchase of cattle. Bank C holds a cheque for £50 drawn by Jones on bank B and relating to his loan to Smith. Bank A holds a cheque for £50 drawn by Smith on bank C, and relating to his butcher's bill. To clear these three cheques, three operations are necessary in the case of each one. The first of these is the crediting of the payee's bank account with £50, and the third is the debiting of the drawer's bank account with £50. These are effected simply by entries in the banks' ledgers. The second, which in theory appears more complex, is the transfer of funds from bank to bank, for bank A owes bank B £50 on Brown's cheque, bank B owes bank C £50 on Jones's cheque, and bank C owes bank A £50 on Smith's cheque. In practice, to effect these settlements, representatives of each bank meet together in a local place of refreshment, present their cheques to each other and proceed to cancel them out. It remains to add, in case this last sentence seems very picturesque, that the London Clearing House is said to have originated in a coffee-house.

Now it makes no difference whether or not these cheques were for £50 or £5,000,000, or whether Brown turns into the Mammoth Meat Packing Syndicate, Jones into the Incorporated Graziers' Society and Smith into a civic corporation or even into an important national government. In theory the banks can cancel out the cheques and in practice they have devised means of doing so. The obstacle of the huge amounts involved has clearly been overcome, and the only necessary condition is that the drawers

and banks are together good for the amount, however large it may be.

Examples of International Payments.—In the article upon FOREIGN EXCHANGES, it is explained that each bank maintains balances with other banks, called its "agents" or "correspondents," in every important financial centre of the world. A London bank will keep a dollar balance in New York, a franc balance in Paris, a mark balance in Berlin, and so on; and American, French and German banks will do the same. We can now construct cases parallel to the three already cited. (1) Brown, a cotton grower in Alabama, sells \$10,000 worth of cotton to Jones, a Manchester spinner. (2) Jones sells £2,000 worth of cotton yarn to Schmidt, a Bremen manufacturer of shirts. (In this calculation, for the sake of simplicity, £1=\$5=Mks. 20.) (3) The Bremen city corporation raise a loan of \$10,000 in New York.

Now here the currency question must be dealt with. Brown wants to be paid in dollars, and Jones can only pay in sterling. Jones, in his turn, wants sterling from Schmidt, who can only pay in marks; and while the Bremen corporation raise a dollar loan, and so undertake to pay principal and interest in dollars, they want their money in marks.

The key obviously lies in bankers' foreign balances.

(a) Brown draws a bill for \$10,000 on Jones, and sells it to his American bank for \$10,000, less discount. So Brown gets his dollars. The American bank sends the bill to its London agent, who presents it to Jones, who pays it with £2,000. This sum of £2,000 is placed by the London bank to the credit of the American bank's balance with it. This settles Brown and Jones.

(b) Jones, when he sold his yarn, told Schmidt to have a confirmed (or irrevocable) credit of £2,000 opened in his (Jones's) favour at a London bank. Schmidt arranged for his Bremen bank to do this with their London agents, where they (the Bremen bank) kept their balance. Once this credit is opened, Jones goes straight to the London bank, identifies himself, hands over the documents relating to the shipment of cotton yarn to Schmidt, and gets his £2,000. The London bank debit the Bremen bank's balance with them to the tune of £2,000, and the Bremen bank debit Schmidt's account Mks. 40,000, plus their own charges. This settles Jones and Schmidt.

Now for the Bremen corporation and their loan. The investors in New York who bought the loan paid \$10,000 in dollars over to the New York issuing house, and the issuing house lodged them to the credit of its account with its New York bankers. It next instructs its bankers to remit Mks. 40,000, which is the mark equivalent, to the Bremen corporation. The New York bank decides to do this through London, so it instructs its London agents to transfer £2,000, the sterling equivalent, from their balance to the Bremen corporation bank's balance, which may be with them or with another London bank. This is done, and the Bremen bank's London agents advise them of the receipt of £2,000, on account of the Bremen corporation's New York loan. Whereupon the Bremen bank credit the Bremen corporation with the mark equivalent of £2,000; *i.e.*, with Mks. 40,000. This settles the loan.

Now just as, in the first instance, no money passed between banks A, B and C, so, in this instance, the total of sterling held in London on either American or German account, remains unchanged. In the first of the last three transactions, the American bank's London balance was increased by £2,000; in the second, the Bremen bank's London balance was decreased by £2,000; in the third, the American balance lost £2,000 to the Bremen balance. The result is a complete "cancel out."

Other Methods.—In the first instance, the debt was paid by means of a bill of exchange; in the second through the medium of a banker's credit (*see* BILL OF EXCHANGE, FOREIGN EXCHANGE); in the third by direct instructions to the bank immediately concerned. In either case the debtor could have bought a banker's draft, mail transfer, cheque or telegraphic transfer drawn in the creditor's currency. The banker's foreign balance would have lost or gained in the same way.

Recent Historical Instances.—One or two cases from recent history may in conclusion be cited.

(1). American Liberty bonds can be tendered at par in pay-

ment of debts due to the American Government. On one occasion the British Government, in anticipation of a coming instalment due on the American debt, paid sterling over to an international finance house's office in London, and arranged for the house to credit the British Government with the equivalent in dollars in New York. It next instructed the finance house to use those dollars to buy Liberty bonds at the current Wall street price, which was then 90. These bonds were tendered in settlement of the instalment to the American Government, who, by its own law, was bound to accept them at par.

(2). When the franc collapsed in the spring of 1924, the French Government arranged for credits to be opened in its favour by banks in London and New York. In other words, these banks engaged to lend the French Government pounds and dollars on demand up to the limits of the credits. The French Government broker then went on the Paris Bourse and sold pounds and dollars to the market, so arresting the fall in the franc. Long before the credits were exhausted, the worst of the crisis was over. The essential point was that the French Government had previously arranged for an adequate supply of pounds and dollars.

(3). When the pound and, later, the lira were stabilized, the British and Italian Governments arranged credits in New York. If speculators had tried to break the stabilization by selling pounds or lire for dollars, the Governments concerned would have drawn on their New York credits, and so put up all the dollars needed to buy up the pounds or lire the speculators were selling.

In short, the system of banker's foreign balances, even if only held in one common foreign centre such as London, provides a ready means of transferring funds from one centre to another right across the world. For the maintenance of these foreign balances by the banks themselves, and for the reasons why the banks add to them and deplete them on their own account, the reader is referred to the article on EXCHANGE, FOREIGN. (See also BALANCE OF TRADE; BANKING AND CREDIT; BILL OF EXCHANGE; CHEQUES.) (N. E. C.)

INTERNATIONAL SOCIETY FOR CONTEMPORARY MUSIC, an organization founded at Salzburg, in 1922, by a number of leading modern musicians, with the object of promoting closer international musical relations by means of annual festivals devoted to representative modern works drawn impartially from all countries. Edward J. Dent, now professor of music at Cambridge university, was elected president, and yearly festivals on the lines indicated have since been regularly held. The society now has some 20 different branches in the principal countries, with headquarters in London at the offices of the British Music Society, which constitutes the British section of the organization.

INTERNATIONAL TELEPHONE AND TELEGRAPH CORPORATION, THE, a holding and operating company, incorporated under the laws of the State of Maryland, U.S.A., having its principal office in New York city. This corporation was organized to develop, in a broad international sense, electrical communication in all its branches. Its present activities through associated companies include:—

(1) The furnishing of telephone service in the Argentine, Brazil, Chile, Cuba, Mexico, Porto Rico, Spain and Uruguay. The Cuban American Telephone and Telegraph Company, owned jointly with the American Telephone and Telegraph Company, operates three submarine telephone cables between Florida and Havana, Cuba.

(2) A radio telephone and telegraph network, which now includes the principal countries of South America, connecting them with North America and Europe. Stations operating (1929) Argentine, Chile, Peru, Colombia, Brazil, Nicaragua, Spain.

(3) The All America Cables Inc. owns and operates some 30,000 nautical miles of submarine telegraph cables and connecting land lines, extending from New York through the West Indies, the Panama Canal Zone and Central America to the west and east coasts of South America. It provides cable service to practically the whole of Latin America.

(4) The Postal Telegraph and Cable Corporation (The Mackay system) owns and operates a complete network of telegraph lines throughout the United States as well as some 36,000 nautical miles

of telegraph cables from the United States and Canada to England, France and Cuba, and from San Francisco via the Hawaiian Islands to the Philippines and China. The Mackay system also owns and operates a point to point wireless telegraph system between the principal cities of the west coast of the United States.

(5) The International Standard Electric Corporation, which is the manufacturing branch of the International, has factories in England, France, Belgium, Germany, Spain, Italy, Austria, Hungary, Czechoslovakia, China and Japan, with a sales organization extending throughout the world. It also maintains fundamental research and development laboratories in London and Paris.

The authorized capital stock of the International Telephone and Telegraph Corporation is 15,000,000 shares of no par value, of which 5,018,278½ shares were outstanding June 30, 1929. The corporation has in addition a funded debt of \$35,000,000 in gold debenture bonds due July 1, 1952, and 59,911,400 convertible gold debenture bonds due Jan. 1, 1939. (A. L. Ho.)

INTERNATIONAL TRADE ASSOCIATIONS AND CONGRESSES. The first striking demonstration of the international character of modern civilisation was the great exhibition of 1851, itself a temporary and loose international association for economic ends. Its successor of 1862 (the International Exhibition in London) contributed to the formation of the first regular association which sought to modify economic conditions by international effort, the International Working Men's Association (see INTERNATIONAL, THE). At about the same time the growth of international trade led to the earliest official international unions, such as that constituted by the International Telegraphic convention of 1865, and the General Postal union of 1874 (see POST AND POSTAL SERVICES). Quite exceptional was the International Sugar union of 1864 which consisted of four countries only and was dissolved in 1875; its successor of 1902 is dealt with below.

The International Metrical union of 1875 dealt with one of the fundamental elements of civilisation; the Latin Monetary union was formed in 1865 but has extended only to five States and failed to prevent the dissociation of the currencies after the war of 1914-18. No private international association for advocating an international currency exists. On the other hand, the advocates of an international language can choose among half-a-dozen associations.

Agriculture.—Although association is notably difficult in agriculture, one of the most effective and beneficent of international associations is the International Institute of Agriculture founded by a conference at Rome in 1905. Due to the firm resolve of a single individual, David Lubin, to create an organisation to minimise the disadvantages under which the unorganised farmers faced the organised railways and buyers, the Institute is a union of States practically universal in scope. Its main work is the publication of complete statistics of crops of all kinds throughout the world, of trade and stocks and of freights and prices. Having established a standard average for the world crop in each product it can produce from the current statistics continually received estimates of the available supplies, which are of the greatest value in stabilising prices and guiding markets. The Institute also studies other international aspects of agriculture, such as comparative legislation, wages, plant diseases. It eschews domestic questions.

The International Seed-testing association founded in 1924, after a series of international conferences, is an important addition to the scheme of international co-operation for agriculture; its members are the official seed-testing associations in the chief agricultural countries.

Private interest in this field is represented by the International Agricultural commission which dates from 1889 and has held numerous international congresses, and by the World Agricultural society, of American origin.

Separate branches of agriculture have their own international institutions such as the International Association of Poultry Instructors and Investigators (1912), the International Dairy federation (1903), and the Permanent Committee of International Congresses of Beekeeping (1897).

The preservation of food is even more important than its production from the international point of view, and with the Inter-

national Institute of Agriculture may be associated the International Institute of Refrigeration. Founded in 1920 (to take the place of a similar association dating from 1900) by an international convention, it is a union of upwards of 30 States and is devoted to the study of cold storage in its scientific and practical aspects. It is governed by two committees, one representing every member State and one containing only 17 persons in all. The United States of America is represented specially in the Institute by the American Association of Ice and Refrigeration.

PERMANENT ASSOCIATIONS

Industry.—International exhibitions, apart from their direct function of celebrating and displaying the achievements of the world's work, are instrumental in the formation of more permanent associations for common effort. From international congresses held in connection with the universal exhibitions at Vienna in 1873 and Paris in 1878 resulted what may be called the first steps in international legislation for industry. They were concerned with the protection of "industrial property" or property in ideas applied in manufacture or embodied in manufactured products (see PATENTS and TRADE MARKS). The first Convention dated 1883 at Paris was followed by the Agreements of Madrid (1891) and the additional Act of Brussels (1900). These instruments were revised at Washington in 1911 and again at The Hague in 1925, though the instruments signed on the last occasion have come into force, only as regards a few countries, including, however, Great Britain, Canada, Germany and Italy. They contained provisions designed to safeguard rights in patents, designs, industrial models and trade marks, and to prevent false indications of origin on goods. The signatory States, 38 in number, of these international measures are known collectively as the International Union for the Protection of Industrial Property, and an International Bureau of the Union was set up at Berne, of which the most important function is the international registration of national trade marks to be protected in the territories of all the States which are parties to the Special Agreement for the International Registration of Trade Marks (one of the Madrid agreements of 1891). The International Union is at present little more than the relation created by a multilateral treaty or common undertaking between several States to enforce certain domestic legislation.

The American counterpart of the above arrangement for the international registration of trade marks is the Pan American Convention of Buenos Aires, 1910, revised at Santiago in 1923, under which two registration offices were to be set up, one at Havana for North America, and one at Rio de Janeiro for South America, but the latter office has not in fact been opened, as several signatories failed to ratify or withdrew from the Convention.

A scheme for the establishment of an International Patent Office at Brussels was considered at a Conference at Paris in 1919, and subsequently a Convention was signed at Paris in 1920, but has not yet become effective. The International Association for the Protection of Industrial Property is a non-official association devoted to the subject in a general way, making specific proposals for official adoption in connection with the international regime established by the above mentioned Agreements and Unions.

Special Industries.—Of international associations relating to a single industry or trade the International Federation of Master Cotton Spinners' and Manufacturers' Associations is the best example. Founded in 1904 to conserve the common interests of the cotton industry in all parts of the world, this Federation of 21 International Associations, through its Committee of Management, exercises positive functions of considerable importance, especially in connection with the supply of raw cotton; in particular, it tabulates statistics of the consumption of cotton by mills and of the stocks held by them, and other data which are now regarded as essential to the proper conduct of the industry.

A similar but smaller Federation of Linen Trade Associations was founded in 1909, but its activities have been suspended since the war of 1914-18. The International Wool Conference, representing six European countries (including Great Britain) meets periodically.

Among other International Trade Associations which are primarily concerned with the direct interests of a single industry or trade, are the International Committee of the Wine and Spirit Trade founded in 1900 by the International Vintners' Congress held on the occasion of the Universal Exhibition at Paris of that year; the International Federation of Master Tailors, 1910, and the International Federation of Seed Crushers (1910, reconstructed 1920) and the Permanent International Bureau of Motor Manufacturers (1919).

All these are private associations of manufacturers or traders, or of their national representative bodies. The absence of such bodies in the case of some of the largest staple trades such as coal, oil, iron and steel, and rubber is worthy of note. On the other hand the number of international associations for the workers in particular trades (see LABOUR) is very large. For the lighting industry the International Committee on Photometry was founded by the International Gas Congress (1900), and succeeded in 1913 by the International Commission on Illumination constituted by national committees from 10 countries.

Power.—The universal aspects of power production are thoroughly studied by the World Power Conference which held its first meeting in 1924 in connection with the British Empire Exhibition at Wembley. The purpose of this Conference, which has a permanent Executive Council, is to consider how the various sources of power may be adjusted nationally and internationally; it is representative of practically the whole world, and works through a series of plenary conferences at long intervals with more frequent sectional meetings. Earlier provision for co-operation between the workers of all countries in this field was made by the International Electrotechnical Commission (1906) consisting of National Committees of 19 countries in which America, North and South, is well represented, and in 1925 was founded the International Union of Producers and Distributors of Electricity, whose first Congress, held in 1926, was attended by representatives of 13 nations. Specialisation has led to the formation of the International Conference of the Leading High Tension Electric Systems, at whose session in June 1927 the above-mentioned bodies and 28 countries were represented.

Commerce.—The first instance of co-operation between States on a multilateral basis in the sphere of international trade or commerce in the proper sense is the Convention of 1890 whereby the International Bureau for the Publication of Customs Tariffs was established. Its functions are simply to supply in five languages (English, French, German, Italian and Spanish) the current Customs Tariffs of all countries. Practically the whole world subscribes to this work.

This modest organ remained the only one in the international body politic to function for the health of commerce until 1921, when the International Bureau of Commercial Statistics began its work. The aim of the States in founding this Bureau, going beyond mere collection of statistical information, was to facilitate the comparison of national statistics by unification on the basis of a common nomenclature which had been elaborated by the Convention of 1913 which established the Bureau. It accordingly publishes an annual bulletin of co-ordinated statistics of imports and exports.

An older, private association for the advancement of statistics of all kinds is the International Statistical Institute, which was founded in 1885, and includes representatives from a large number of States; its permanent office dates from 1913.

International congresses of a non-official character dealing generally with commerce and industry began to be held in the eighties of last century, and were organised periodically by the International Congress of Chambers of Commerce and Commercial and Industrial Associations until the World War. In 1919 a Conference held at Atlantic City (U.S.A.) of representatives of commerce from that country, Great Britain, France, Italy and Belgium, decided to found the International Chamber of Commerce which held its first Congress at London in 1921, where 35 countries were represented, and thenceforward others biennially, the fourth Congress at Stockholm in 1927 being attended by 800 delegates from 35 countries. The International Chamber has also a permanent organisation consisting of National Committees electing

representatives to a Council whose decisions are carried out by the Secretariat. The actual members of the International Chamber are either bodies such as local Chambers of Commerce, and National Trade Associations, or individual firms or companies.

The main aim of the Chamber is to foster international trade by promoting harmonious commercial relations between the various national interests, the domestic side of their work, and to remove restrictions on trade, the more public side of their work, which brings them into contact with the framework of laws and regulations within which trade has to find its way.

At their 1921 Congress the International Chamber adopted 27 Resolutions dealing with subjects ranging from Double Taxation to the Reform of the Calendar, and from the Channel Tunnel to Reconstruction in Poland. While a good many of these Resolutions dealt with matters of temporary importance connected with the War's upheavals, others dealt with matters of permanent interest to Commerce such as double taxation, international arbitration, unification of tariff nomenclature, treatment of commercial travellers, and in these cases the preliminary work of this International body has been followed either by bilateral government action or by definite provision of the reforms desired in international conventions, such as the Protocol on Arbitration Clauses of 1923, and the Convention on Arbitration Awards of 1927, which give effect precisely to the resolution on this subject of 1921 referred to above. The International Chamber has itself established a Court of Arbitration for commercial disputes and appoints Arbitrators.

With a view to facilitating the passage into law of the measures, which international opinion indicates as appropriate for the benefit of commerce, the International Parliamentary Conference on Commerce was founded in 1914, and its Assembly in 1927 was attended by representatives of 43 countries, appointed for the most part by the national Parliaments themselves. It brings together the experience of the several legislative bodies in dealing with commercial matters, and its activities are thus complementary with those of the International Chamber. At the meeting of this Conference in 1919 yet another Association was founded, the International Institute of Commerce which, under the direction of the General Council of the Parliamentary Conference, is concerned with commercial statistics and legislation, including Commercial Treaties; its membership (17 States have officially adhered), is relatively restricted.

The Union of International Fairs, founded in connection with the International Fair of Milan (1925-6), describes itself sufficiently. There is no corresponding body for international exhibitions, though these have, as we have seen, been instrumental in promoting the formation of many international associations of various kinds. Their popularity has, however, increased to the point at which it has become necessary to suggest some understanding among the chief industrial countries as to their limitation.

Mention of separate associations for special industries or trades has already been made. An Association of a different type is the International Sugar Union of 1902, being an isolated example, apart from the earlier Sugar Union of 1864, of a Union of States for the regulation, for economic and not humanitarian reasons, of the trade in a single commodity. It provided for the abolition of bounties and the limitation of protective duties and, to supervise the execution of the various provisions of the Convention, created an international committee with a permanent office at Brussels. The Union worked effectively until 1912 when Great Britain left it; it ceased entirely in 1920.

Transport and Communications.—As is natural, the field of transport and communications is well covered by international bodies. International association among shipping companies did not take proper shape until the 20th century however, for the so-called Shipping Conferences which were first formed in the seventies of the 19th century, though they may include fleets under several flags, are hardly to be regarded as "international" in the sense in which the word is used in this article. They are limited in scope of course to specific trades and correspond rather to those limited industrial associations which are formed by the organised groups of a few countries for definite business purposes such as

the regulation of competition (*see* under SHIPPING, TRUSTS and CARTELS). The Baltic and White Sea Conference (1905) has a much wider scope than its title indicates. Representing ship-owners and shipbrokers in 19 countries it is the main authority for the standard form of charter party. It also seeks to fix minimum freights. The International Maritime Committee for the unification of Maritime Law had been founded in 1897 and itself created the national committees through which it works in 16 countries. The Committee was responsible for the initial preparation of the International Conventions on collisions and salvage signed at the Brussels diplomatic Conference in 1910 which have since been widely adopted as national law. Conventions on the limitation of shipowners' liability, maritime mortgages and liens, and bills of lading, which the Committee similarly prepared, have also been adopted by diplomatic Conferences and their inclusion in the national legislative systems is proceeding.

The Permanent International Association of Navigation Congresses (1902) consisting of representatives of 43 governments and other bodies and individuals deals mainly with technical matters.

The International Shipping Federation (1909), a federation of the shipowners' associations of 8 European countries, is concerned exclusively with their interests as employers. The International Shipping Conference which first met in 1921, consists of the national organisations of the shipping industries in 15 countries and is concerned with the general policy of the shipping industry in all questions other than labour. It seeks to establish uniformity in practice and action; it co-operates with the International Chamber of Commerce.

The group of international associations which deal with railways illustrates well the international regulation of the world. As long ago as 1882 the International Conference for promoting Technical Uniformity on Railways was founded at Berne (Switzerland being regarded as the "turn-table" of Europe) to develop international railway traffic and uniformity in certain railway equipment; this is an association of States, or of State Railway Administrations, the members consisting of those European States in which the railways are of standard gauge, and thus form a system capable of unification.

In 1885 there was founded an International Association of the Railway Congress, replaced in 1919 by a body of the same name whose effective members are the Railway Administrations of all the important countries of the world (except Russia); its functions are to promote general railway progress by congresses and publications.

The well known Berne Convention for the carriage of goods by rail of 1890, revised in 1924, and adopted by the same States as those represented in the Technical Conference described above, provided the common rules whereby goods could be sent over the railways of any number of these States by a single consignment, and this necessitated the establishment of the Central Office for International Railway Traffic at Berne in 1893, an institution created by the States themselves which has financial duties as a clearing house between the several railway administrations, and powers to settle disputes referred to them by the latter.

POST-WAR RECONSTRUCTION

The post-war reconstruction of European transport included new institutions for facilitating the international working of railways. The International Railway Wagon Union was founded in 1921 by the Convention of Stresa, again by the standard gauge countries of Europe, to manage the common user of wagons. A little later as a consequence of resolutions of the Conference at Porto Rosa (November 1921) and Genoa (May 1922) the International Railway Union, which includes the railway administrations of all the larger European countries, not excluding Russia and Spain, and also those of China and Japan, came into being with the general function of unifying and improving railways and railway working. It is preparing a scheme of nomenclature for international tariffs and a basis for international statistics.

The European Time Table Conference which secures correspondence in the timing of the principal European passenger services on the standard gauge railways, was put on a permanent foot-

ing as from 1923 by the Lucerne Conference, while the Union for International Users of Passenger Rolling Stock established by the same Conference regulates the reciprocal use of passenger rolling stock by the several administrations, also for Europe only.

America has her own International Railway Association in the shape of the Permanent Pan American Railway Committee founded in 1902 with the specific object of securing the construction of a through railway joining the United States and Mexico to Central and South America. This is an offshoot of the Pan American Union and its members are the American Republics concerned.

The common interests of the more restricted types of transport are cared for by the International Union of Tramways, Local Railways, and Public Motor Transport which corresponds with, and originated in the same year (1885) as, the International Association of Railway Congresses; it was reconstructed in 1919. Its members include local transport undertakings and public bodies.

Road transport in general is represented by the International Association of Recognised Automobile Clubs (1904) on the more private and sporting side, and by the Permanent International Association of Road Congresses (1908), an association of 38 governments.

The organ for the international control of air traffic is the International Commission for Air Navigation which, under the International Air Convention of 1919, makes rules dealing with the registration, marking and airworthiness of aircraft, and with the issue of certificates of competency for their operating crews, with the lights and signals to be used by aircraft, and the conduct of air traffic generally. The Commission does not administer these rules or otherwise directly control air transport, but the establishment by a central body of these governing rules, which are adopted of course by the parties to the Convention (now some 25 in number), shows how this latest form of transport is internationalised to a definitely greater degree than shipping, the form with which it has the strongest analogies.

Somewhat similar to the International Maritime Law Committee is the International Technical Committee of Legal Experts for Aviation (*Comité International Technique d'Experts Juridiques Aériens*) established in pursuance of recommendations of the International Conference on Private Aerial Law of 1925. It consists of experts appointed by over 30 States and prepares draft international conventions on legal questions such as, for example, the liability of the carrier by air for loss and damage.

Private interest in aviation is co-ordinated by the International Aeronautic Federation (1905) and commercial effort by the Air Traffic Association (1919), which consists of certain important air service companies. The former body is an association of Aero Clubs which is concerned with flying as a sport and the records it authenticates are internationally accepted.

Communications.—Postal and telegraphic services naturally called for their appropriate international organs at an early stage, as has already been stated. The Postal Union is now truly universal in scope, embracing some 175 different countries including dependencies. Ordinary and wireless telegraphic communications have their corresponding unions and international bureaux dating respectively from 1865 and 1906, while the recent International Advisory Committee on Long Distance Telephone Communications brings together the administrations of some 18 European countries (for further details see *POST AND POSTAL SERVICES*).

What was described by Mr. Hoover in his closing address as the largest international conference in history, the third International Radio Telegraph Conference of Washington, held in October and November, 1927, brought together representatives of over 70 different Governments and of all the important Wireless Companies as well as those of several international institutions among which were the International Commission for Air Navigation and the International Shipping Conference. This Conference after a thorough survey of the great developments which had taken place in radio telegraphic communication since the last Conference, that of 1912, reached unanimous conclusions in the shape of the International Radio Telegraph Convention and Regulations of November 25, 1927; this instrument was signed by repre-

sentatives of over 70 Governments, and provided for the general control of radio electric communication and for the assignment of different bands of wave lengths covering the whole range from about 6 metres to 30,000 metres to the various services such as, for example, long distance trans-oceanic services and broadcasting. The new Convention came into force on January 1, 1929, and instituted a new international body in the shape of a Technical Advisory Committee with the function of studying technical and related questions on this subject. This is attached to the existing International Bureau of the Telegraph Union which acts as the Secretariat of the Radio Telegraph Union and will continue to carry out any administrative duties arising out of the revised Regulations which the Conference adopted.

Professional.—The Permanent Committee of International Congresses of Actuaries (1895) is devoted generally to the interests of that profession and the International Association of Accountancy (1911) seeks to systematize terminology and practice in book-keeping. They are both private organisations, but the former has public administrations among its members and the latter receives some State subventions.

Miscellaneous.—The International Co-operative Alliance was founded in 1895 to develop co-operative methods in all countries and relations between the national societies, while in 1924 the International Co-operative Wholesale Society, consisting of all the European national societies of this kind, was founded with a similar object (see *CO-OPERATION*). Advocating a similar ideal, but for adoption by the various Governments and not individuals, the International Committee to promote universal Free Trade was founded in 1921 and embraces the national Free Trade Societies of 14 countries. Its counterpart in the shape of a union of societies for the promotion of economic nationalism or separatism not unnaturally does not exist.

Relation to League of Nations.—This habit of associating internationally and this endeavour to treat the world as one for an ever-increasing number of purposes, grows continually and has a cumulative effect. Only a world-wide catastrophe such as the war of 1914-18 can interrupt it, and that war has in the sequel had the effect of greatly stimulating these international movements, and it has given them a supreme international association of States, the League of Nations, which serves to focus their various efforts, and to secure that real effect is given to those of their aims which the world is generally ready to adopt.

The Covenant of the League of Nations lays down in Article 24 that there shall be placed under the direction of the League all international bureaux already established by general treaties, if the parties to such treaties consent, and that all such international bureaux and all commissions for the regulation of matters of international interest hereafter constituted shall be placed under the direction of the League. The bureaux here referred to are of course the creation of States; unofficial international bureaux or associations may at their request be placed under the League's directions; the tendency, however, is for such international bodies not to do so, but to work with the League Organizations. The execution of the extensive programme which the World Economic Conference of 1927 laid down, in the sphere of international economic questions, and which covers mostly the same ground as the recommendations of the various International Associations dealt with above, is entrusted to the Economic Committee of the League of Nations, aided by the Consultative Committee. It has been decided that on the latter body should be represented the International Chamber of Commerce (3 members), while co-operation is intended with such bodies as the International Management Institute and the International Co-operative Alliance.

Representatives of several international organizations, such as the International Shipping Conference, took part in the General Conference on Communications and Transit in 1927, and provision is made in the new statute for this branch of the League for the participation in its work in an advisory capacity of representatives of international organizations. It is thus becoming clear that these bodies, for the most part private in origin and constitution, are likely to find in this sphere the opportunity for their most effective work, since they can contribute to the work

of the paramount official international association the best available experience and generally matured policy.

International law has so far made no provision for giving a definite status to international associations, but the question of regularizing their position (which is especially desirable when they are not the creation of specific agreement between States) is on the agenda of the League of Nations Committee for the Codification of International Law for 1928.

BIBLIOGRAPHY.—The Handbook of International Organisations published by the League of Nations gives particulars of international associations on all subjects; the League's Quarterly Bulletin gives particulars of international conferences held or forthcoming, also a list of current publications by international organisations.

P. B. Potter in his "Introduction to the Study of International Organisation" (1922) has chapters on international associations, official and private, and gives a brief bibliography. More recent and full is W. Kaufmann's "Les Unions Internationales de Nature Economique" (1924) with a full bibliography published in the *Recueil des Cours de l'Académie de Droit International*. See also **MONETARY CONFERENCE**. (E. J. E.)

INTERPELLATION, a term meaning, in general, an interruption, more particularly used of a method of procedure adopted in some of the legislative chambers of continental Europe, especially those of France and Italy. It was originally confined to the asking of a question, after due notice, on some affair of State. It is now, however, the chief means by which the policy or action of the Ministry of the day is challenged. An interpellation can be brought on without the consent of the minister to be attacked; it is usually made the subject of a general debate, and ends with a vote of confidence or want of confidence in the Ministry.

INTERPENETRATING MOULDINGS, in architecture, are mouldings of the same or different profiles, which meet at an angle, as at the top of an arch or the corner of an opening, and instead of stopping at the line of intersection, are carved as though they passed through each other and continued on until received by some projecting member or surface. Such a juncture is known as an interpenetration. This treatment is characteristic of flamboyant Gothic (see **FLAMBOYANT STYLE**), especially in France and Germany.

INTERPLEADER: see **PRACTICE AND PROCEDURE**.

INTERPOLATION, in mathematics, the process of obtaining intermediate terms of a series of which particular terms are known; from the Latin *interpolare*, to alter, or insert something fresh, connected with *polire*, to polish. The logarithms, for instance, shown in Table I, may be regarded as terms of a series,

TABLE I.

No.	Log.	1st diff.
.	.	+
.	.	.
.	.	.
2.70	.4314	.
		16
2.71	.4330	.
		16
2.72	.4346	.
		16
2.73	.4362	.
		16
2.74	.4378	.
		15
2.75	.4393	.
.	.	.
.	.	.

and the logarithm of a number between 2.70 and 2.75 may be found by interpolation from the table. The process of obtaining the logarithm of a number lying outside these limits would be *extrapolation*; the formulae which apply to interpolation apply in theory to extrapolation, but in practice special precautions as to accuracy are necessary. The present article deals only with interpolation.

The term is usually limited to those cases in which there are two quantities, x and u , which are so related that when x has any arbitrary value, lying perhaps between certain limits, the value of u is determinate. There is a given series of associated

values of x and of u , and interpolation consists in determining the value of u for any arbitrary value of x , or the value of x for any arbitrary value of u , lying between two of the values in the series. Either of the two quantities may be regarded as a function of the other; it is convenient to regard one, x , as the *independent variable*, the other, u , being treated as the *dependent variable*, i.e., as a function of x . If, as is usually the case, the successive values of one of the quantities proceed by a constant increment, this quantity is to be regarded as the independent variable. The two series of values may be tabulated, those of x being placed in a column (or row), and those of u in a parallel column (or row); u is then said to be *tabulated in terms of x*. The independent variable x is called the *argument*, and the dependent variable u is called the *entry*. Interpolation, in the ordinary sense, consists in determining the value of u for a value of x intermediate between two values appearing in the table. This may be described as *direct interpolation*, to distinguish it from *inverse interpolation*, which consists in determining the value of x for a value of u intermediate between two in the table. Graphically, the data for interpolation are certain ordinates of the graph of u with regard to x , and direct interpolation consists in deducing the magnitude of any other ordinate whose position is given, while inverse interpolation consists in determining the position of an ordinate whose magnitude is given. The methods employed can be extended to cases in which the value of u depends on the values of two or more independent quantities x, y, \dots

The subject will be treated under three heads: I. Direct Interpolation (equal intervals), II. Direct Interpolation (unequal intervals), III. Inverse Interpolation.

I. DIRECT INTERPOLATION (EQUAL INTERVALS)

1. **Notation and Arrangement.**—We have a table showing the values of a quantity u corresponding to values of a quantity x . The values of x proceed by a constant increment h . We denote the values of x by $\dots x_0, x_1, x_2, \dots$, so that $x_m = x_0 + mh$; and the corresponding values of u are $\dots u_0, u_1, u_2, \dots$. We want to find u_θ , which is the value of u corresponding to $x_\theta = x_0 + \theta h$; for preciseness, we can say that θ lies between -1 and $+1$.

The first step, usually, is to arrange the u 's in a vertical column, followed by columns containing the successive differences. The differences of the u 's are the *first differences*, those of the first differences are the *second differences*, and so on. These are also called *differences of the first, second, \dots order*.

The differences, like the u 's, have to be distinguished by suffixes. There are three systems, the advancing-difference, the receding-difference and the central-difference. On the *advancing-difference* system, $u_1 - u_0$ is regarded as the first difference of u_0 , and is denoted by Δu_0 , so that $\Delta u_1 - \Delta u_0$ is $\Delta^2 u_0$; on the *receding-difference* system, which is less important, $u_1 - u_0$ is the first difference of u_1 . On the *central-difference* system, $u_1 - u_0$ is a difference corresponding to the interval between u_0 and u_1 , and is therefore denoted by $\delta u_{\frac{1}{2}}$, so that $\Delta^2 u_{-\frac{1}{2}}$ is $\delta^2 u_0$; there is also a symbol μ for the mean of any two adjacent entries in a column, so that $\mu u_{\frac{1}{2}} = \frac{1}{2}(u_0 + u_1)$, $\mu \delta u_0 = \frac{1}{2}(\delta u_{-\frac{1}{2}} + \delta u_{\frac{1}{2}})$, and so on. The system is more fully set out in the article **CALCULUS OF DIFFERENCES**.

2. **Fundamental Principle.**—The methods which we are considering are, in general, applicable when the result of taking successive differences is to bring us ultimately to differences of a certain order, say the k th, which are practically constant, so that the differences of the next order, the $(k+1)$ th, are zero or at any rate are negligible. The fundamental principle then is that we assume that interpolation can be performed as if these latter differences were actually zero. The implication of this assumption will be considered further in §6. The assumption may, in the case of a mathematical table, be made as a matter of course; for the table is constructed so as to be used in this way. In other cases it must be justified by the facts.

3. **Interpolation by First Difference.**—In Table I. we see that, as x increases, u increases steadily. We therefore use the

principle of proportional parts, i.e., we assume that for any increase in x there is a proportional increase in u . Thus we can say that the logarithm of 2.725 is $.4346 + 8$ (where "+8" denotes the addition of 8 to the last figure of the tabulated entry, i.e., means $.0008$) = $.4354$; and similarly $\log 2.7225 = .4350$.

Algebraically, we express the relation between x and u by saying that u is of the form $p + qx$. It follows that the formula for u_θ is

$$u_\theta = u_0 + \theta(u_1 - u_0) = u_0 + \theta\Delta u_0. \quad (1)$$

Graphically, this means that we take the upper boundary of the graph, between u_0 and u_1 , to be a straight line joining the tops of the corresponding ordinates.

To find $\log 2.724$ we should have to add .4 of 16 = 6.4. But it would be incorrect to write the result as $.43524$; for this would imply that we could find the logarithm to five decimal places, which the table does not enable us to do. We can do either of two things. If we only want the best value, to four places, that we can get, we must take .4 of 16 to be 6, so that our answer is $.4352$. But a better method, if we are going to use $\log 2.724$ for further calculation, is to retain an extra two or three figures in our work. We therefore, for the time being, write the logarithm in the form $.435240$ or $.435240$; any extra figures retained in this way are dropped at the conclusion of our work, the preceding figure being adjusted if necessary. This principle applies throughout the whole of our work.

As stated above, the table shows that as x increases u increases steadily. But this does not mean that the second differences of u are absolutely zero; it only means that when we are working to four places of decimals they are negligible. That they do exist, can be seen either by taking more correct values, as in Table II., or by taking values of x at greater intervals, as in Table III.

TABLE II.				TABLE III.			
No.	Log.	1st diff.	2nd diff.	No.	Log.	1st diff.	2nd diff.
.	.	+	-	.	.	+	-

2.75	.4393327	.	.	3.0	.4771	.	.
.

Similarly we could detect the existence of differences of the third or a higher order.

The sequence of differences, of whatever order, will present some irregularities. These are due to the fact that the tabulated values are necessarily not exact. Thus in Table I. the occurrence of the difference 15 immediately following a series of 16's is due to the entry for 2.74 being slightly too large (as will be seen from Table II.), while the entry for 2.75 is slightly too small. A similar explanation applies to the 57 in Table II.: the entry for 2.73 is too small, and that for 2.74 is too large.

4. **Interpolation with Second Differences.**—If we have to use second differences, but do not need third differences, the formula is

$$u_\theta = u_0 + \theta\Delta u_0 + \frac{1}{2}\theta(\theta-1)\Delta^2 u, \quad (2)$$

in which $\Delta^2 u$ may be either $\Delta^2 u_0$ or $\Delta^2 u_{-1}$. It is usually best to take the one which lies nearest in the table (see Table II. or Table III.); thus if θ lies between $-\frac{1}{2}$ and $+\frac{1}{2}$ we should use $\Delta^2 u_{-1}$, but if it lies between $+\frac{1}{2}$ and $+\frac{3}{2}$ we should use $\Delta^2 u_0$.

In most cases in which this formula has to be used, $\Delta^2 u$ is small: a convenient form for calculation is then

$$u_\theta = u_0 + \theta\{\Delta u_0 - \frac{1}{2}(\theta-1)\Delta^2 u\}. \quad (3)$$

5. **General Formula.**—The general formula, involving dif-

ferences beyond the second, may be written in terms of advancing differences or of central differences.

(i.) The advancing-difference formula is

$$u_\theta = u_0 + \theta\Delta u_0 + \frac{\theta(\theta-1)}{2!}\Delta^2 u_0 + \frac{\theta(\theta-1)(\theta-2)}{3!}\Delta^3 u_0 + \dots, \quad (4)$$

in which the coefficients of $u_0, \Delta u_0, \Delta^2 u_0, \dots$ are those of the powers of Δ in the expansion of $(1+\Delta)^\theta$ by the binomial theorem. If differences of order exceeding k are negligible, the series ends with a term in $\Delta^k u_0$. This is known as the *Gregory-Newton formula*.

(ii.) The central-difference formula is of two forms, but we need only consider one, viz., that which uses u_0 and the central differences on or adjoining a horizontal line through it. Thus (see §1) the differences involved are

$$u_0, \mu\delta u_0 = \frac{1}{2}(\delta u_{-1} + \delta u_1), \delta^2 u_0, \mu\delta^2 u_0 = \frac{1}{2}(\delta^2 u_{-1} + \delta^2 u_1), \delta^4 u_0, \dots$$

Let us write (see CALCULUS OF DIFFERENCES).

$$\begin{aligned} c_1 &\equiv \mu\delta u_0 - \frac{1}{6}\mu\delta^3 u_0 + \frac{1}{20}\mu\delta^5 u_0 - \frac{1}{140}\mu\delta^7 u_0 + \dots \\ c_2 &\equiv \delta^2 u_0 - \frac{1}{12}\delta^4 u_0 + \frac{1}{90}\delta^6 u_0 - \frac{1}{360}\delta^8 u_0 + \dots \\ c_3 &\equiv \mu\delta^3 u_0 - \frac{1}{4}\mu\delta^5 u_0 + \frac{7}{120}\mu\delta^7 u_0 - \dots \\ c_4 &\equiv \delta^4 u_0 - \frac{1}{6}\delta^6 u_0 + \frac{7}{240}\delta^8 u_0 - \dots \\ c_5 &\equiv \mu\delta^5 u_0 - \frac{1}{3}\mu\delta^7 u_0 + \dots \\ c_6 &\equiv \delta^6 u_0 - \frac{1}{4}\delta^8 u_0 + \dots \end{aligned} \quad (5)$$

Then the formula is

$$u_\theta = u_0 + c_1\theta + c_2\frac{\theta^2}{2!} + c_3\frac{\theta^3}{3!} + c_4\frac{\theta^4}{4!} + \dots \quad (6)$$

6. **Basis of Formulae.**—Formulae (1) and (2) may be regarded as particular cases of (4), differences after the first in the one case, and after the second in the other, being negligible. But it is more instructive to consider them separately.

(i.) For first-difference interpolation we take the upper boundary of the graph to be a straight line; and this straight line must obviously pass through the tops of the ordinates representing u_0 and u_1 . Or, conversely, taking Table I. for an illustration, let us suppose that we have the graph drawn with absolute accuracy. Then, if we are unable to measure the magnitude of u_0 and u_1 and intermediate ordinates to a greater accuracy than is represented by four significant figures, we are unable to see that it is anything but a straight line. The equation to the graph must therefore be taken to be $u_\theta = u_0 + \theta\Delta u_0$.

(ii.) Now suppose that (see Table II.) we are able to measure to a degree of accuracy represented by six or seven significant figures. Then the boundary of the graph will appear to be a parabola, its equation being of the form $u = p + qx + rx^2$. To determine p, q , and r we require three ordinates. If we take these to be u_0, u_1 , and u_2 , the equation to the graph becomes $u_\theta = u_0 + \theta\Delta u_0 + \frac{1}{2}\theta(\theta-1)\Delta^2 u_0$; if we take them to be u_{-1}, u_0 , and u_1 , the equation is $u_\theta = u_0 + \theta\Delta u_0 + \frac{1}{2}\theta(\theta-1)\Delta^2 u_{-1}$. The connection between the equation being of the form $u = p + qx + rx^2$ and the formula not going beyond second differences is that, if u is of this form, third differences of the u 's are 0. Table IV. illustrates this for the particular case of $u \equiv x^2$.

TABLE IV.							
x	0	1	2	3	4	5	...
$u \equiv x^2$	0	1	4	9	16	25	...
1st diff.		1	3	5	7	9	...
2nd diff.			2	2	2	2	...
3rd diff.				0	0	0	...

(iii.) Finally, suppose that differences beyond those of order k are negligible, and let us, for simplicity, take k to be even and $= 2g$. Then u is a polynomial in x , of degree $k \equiv 2g$. If we want to use advancing differences, we find the constants in this polynomial by passing a curve of degree k through the tops of the

ordinates $u_0, u_1, u_2, \dots, u_{2g}$; and we then get the formula

$$u_p = u_0 + \phi \Delta u_0 + \frac{\phi(\phi-1)}{2!} \Delta^2 u_0 + \dots + \frac{\phi(\phi-1) \dots (\phi-2g+1)}{(2g)!} \Delta^{2g} u_0 \quad (7)$$

If, on the other hand, we pass the curve through the tops of the ordinates $u_{-g}, u_{-g+1}, \dots, u_{-1}, u_0, u_1, \dots, u_{g-1}, u_g$, we get the central-difference formula for u_g in terms of $u_0, \mu \delta u_0, \delta^2 u_0, \dots, \delta^{2g} u_0$.

(iv.) An important fact is that, viewed algebraically, there is no essential difference between the advancing-difference formula and the central-difference formula. If, as in (iii.), we pass a curve of degree $2g$ through the tops of the ordinate $u_0, u_1, u_2, \dots, u_{2g}$, the formula for u given by this curve is a central-difference formula for interpolation between $u_{g-\frac{1}{2}}$ and $u_{g+\frac{1}{2}}$, but it is also an advancing-difference formula for interpolation between u_0 and u_1 , and a receding-difference formula for interpolation between u_{2g-1} and u_{2g} .

7. Central-difference Formulae.—A central-difference formula, in the general sense, is one which involves differences, or pairs of differences, lying on or close to a horizontal line in the table. There are several of these, but they are all equivalent either to (6) or to a formula constructed on the same principle but involving $\mu u_1, \delta u_1, \mu \delta^2 u_1, \dots$. Three of these, known to Newton but subsequently discovered by other writers, may be mentioned.

(a) The *Newton-Gauss formula* is a zigzag formula involving $u_0, \delta u_1, \delta^2 u_0, \delta^3 u_1, \dots$.

(b) The *Newton-Stirling formula*, easily obtained from the above, involves $u_0, \mu \delta u_0, \delta^2 u_0, \mu \delta^3 u_0, \dots$, and becomes (6) if the coefficients of $\theta, \theta^2, \theta^3, \dots$ are collected.

(c) The *Newton-Bessel formula* involves $\mu u_1, \delta u_1, \mu \delta^2 u_1, \delta^3 u_1, \dots$. If the coefficients of $\theta - \frac{1}{2}, (\theta - \frac{1}{2})^2, (\theta - \frac{1}{2})^3, \dots$ in this formula are collected, we get an alternative formula to (6), for use throughout an interval in the table.

8. Sub-tabulation.—When the values of u have been tabulated for values of x , proceeding by a difference h , we may want to deduce a table in which the differences of x are h/n , where n is an integer. For the common case of $n=10$, we can proceed by two steps, first halving the interval, and then dividing the new interval into fifths.

(i.) For halving the interval we have

$$u_{\frac{1}{2}} = \frac{1}{2}(U_0 + U_1), \quad (8)$$

where

$$U \equiv u - \frac{1}{8} \delta^2 u + \frac{3}{128} \delta^4 u - \frac{5}{1024} \delta^6 u + \dots \quad (9)$$

(ii.) For any other value of n than 2 we use a formula due to J. D. Everett. If we write $\phi \equiv 1 - \theta$, *Everett's formula* is

$$\left. \begin{aligned} u_\theta &= \theta u_1 + \frac{\theta(\theta^2-1^2)}{3!} \delta^2 u_1 + \frac{\theta(\theta^2-1^2)(\theta^2-2^2)}{5!} \delta^4 u_1 + \dots \\ &+ \phi u_0 + \frac{\phi(\phi^2-1^2)}{3!} \delta^2 u_0 + \frac{\phi(\phi^2-1^2)(\phi^2-2^2)}{5!} \delta^4 u_0 + \dots \end{aligned} \right\} \quad (10)$$

For actual calculation we replace $\theta u_1 + \phi u_0$ by $u_0 + \theta \Delta u_0$. Then, if we write

$$\theta V_n \equiv \frac{\theta(\theta^2-1^2)}{3!} \delta^2 u_n + \frac{\theta(\theta^2-1^2)(\theta^2-2^2)}{5!} \delta^4 u_n + \dots \quad (11)$$

we have, for interpolation between u_0 and u_1 ,

$$u_\theta = u_0 + \theta \Delta u_0 + \theta V_1 + 1-\theta V_0, \quad (12)$$

the successive values of θ being $1/n, 2/n, \dots, (n-1)/n$. For interpolation between u_1 and u_2 we have, with the same succession of values of θ ,

$$u_{1+\theta} = u_1 + \theta \Delta u_1 + \theta V_2 + 1-\theta V_1. \quad (13)$$

The values of $1-\theta V_1$ in (13) are exactly the same as those of θV_1 in (12), but in the reverse order. The process of constructing the new table is therefore very simple.

II. DIRECT INTERPOLATION (UNEQUAL INTERVALS)

9. When the differences of consecutive x 's are not all equal, we use formulae analogous to ordinary interpolation-formulae, but with the differences prepared in a special way. The best-known formulae are Newton's (original) formula and Lagrange's formula; the former uses "divided" differences.

Let the tabulated values of x be \dots, a, b, c, d, \dots , the corresponding values of u being denoted by $\dots, f(a), f(b), f(c), f(d), \dots$. Then our table is of the form:—

x	u	Divided Differences			
		1st	2nd	3rd	...
.
.
a	$f(a)$	$f(a, b)$.	.	.
b	$f(b)$	$f(b, c)$	$f(a, b, c)$.	etc.
c	$f(c)$	$f(c, d)$	$f(b, c, d)$	$f(a, b, c, d)$	etc.
d	$f(d)$
.
.

In this table

$$\left. \begin{aligned} f(a, b) &\equiv \frac{f(b) - f(a)}{b - a}, f(b, c) \equiv \frac{f(c) - f(b)}{c - b}, \dots \\ f(a, b, c) &\equiv \frac{f(b, c) - f(a, b)}{c - a}, f(b, c, d) \equiv \frac{f(c, d) - f(b, c)}{d - b}, \dots \\ f(a, b, c, d) &\equiv \frac{f(b, c, d) - f(a, b, c)}{d - a}, \dots \end{aligned} \right\} \quad (14)$$

etc.

The quantities $f(a, b) \dots$ in the first line are called *divided differences of the first order*; those in the second line are *divided differences of the second order*; and so on. If u is a polynomial of degree k in x , the divided differences of order $k+1$ are all 0. It should be observed that the value of any divided difference is independent of the order in which the u 's involved in it are arranged; thus $f(a, b) = f(b, a)$, $f(a, b, c) = f(a, c, b)$, etc.

Newton's formula for unequal intervals is

$$f(x) = f(a) + (x-a)f(a, b) + (x-a)(x-b)f(a, b, c) + \dots, \quad (15)$$

the series continuing until the differences are zero or negligible. This formula covers all those with which we have so far dealt; thus the Newton-Gauss formula (§ 7) is obtained by taking the x 's in the order 0, 1, -1, 2, -2, \dots .

The method was subsequently modified by Newton, in a manuscript written in 1676 but not known to the world until 1926. Another method, similar to this modified method, but not identical with it, is that of "adjusted differences."

Lagrange's formula is

$$\left. \begin{aligned} f(x) &= \frac{(x-b)(x-c)(x-d) \dots}{(a-b)(a-c)(a-d) \dots} f(a) \\ &+ \frac{(x-a)(x-c)(x-d) \dots}{(b-a)(b-c)(b-d) \dots} f(b) \\ &+ \frac{(x-a)(x-b)(x-d) \dots}{(c-a)(c-b)(c-d) \dots} f(c) + \dots \end{aligned} \right\} \quad (16)$$

This gives exactly the same result as Newton's formula. It is not so convenient for calculation as the latter, and it does not show how many u 's have to be taken into account; but it is important in dealing with the theory of the subject.

III. INVERSE INTERPOLATION

10. Inverse Interpolation: Simple Cases.—In all cases of inverse interpolation we have to pay special attention to the degree of accuracy of the result. This depends largely, in ordinary

cases, on the initial figure of the first difference.

If the first difference is practically constant, inverse interpolation is very simple. The direct formula

$$u_\theta = u_0 + \theta \Delta u_0$$

gives

$$\theta = (u_\theta - u_0) / \Delta u_0.$$

If we have to go to second differences, the direct formula is

$$u_\theta = u_0 + \theta \Delta u_0 + \frac{1}{2} \theta (\theta - 1) \Delta^2 u_0 \\ = u_0 + \theta \left\{ \Delta u_0 + \frac{1}{2} (\theta - 1) \Delta^2 u_0 \right\},$$

where, if θ lies between 0 and 1, $\Delta^2 u$ may be either $\Delta^2 u_{-1}$ or $\Delta^2 u_0$. We can calculate the expression in $\{ \}$ by taking an approximate value of θ ; and then θ is found more accurately by dividing $u_\theta - u_0$ by this expression.

11. **General Formula.**—If third or higher differences have to be taken into account there are two methods.

(i.) We can use the general formula (6), viz.:

$$u_\theta = u_0 + c_1 \theta + c_2 \frac{\theta^2}{2!} + c_3 \frac{\theta^3}{3!} + c_4 \frac{\theta^4}{4!} + \dots,$$

and proceed by successive approximations. By transposition and division, we get

$$\theta = \left(u_\theta - u_0 - c_2 \frac{\theta^2}{2!} - c_3 \frac{\theta^3}{3!} - c_4 \frac{\theta^4}{4!} - \dots \right) \div c_1.$$

We begin with an approximate value of θ . Substituting this on the right-hand side, we get a closer approximation; and so on.

(ii.) The above method is only applicable when the intervals in x are equal. An alternative method, suitable for cases of unequal intervals, but not always applicable, is to invert the table—i.e., to interchange the x column and the u column and find divided differences of the x 's—and proceed by direct interpolation.

BIBLIOGRAPHY.—Edmund T. Whittaker and G. Robinson, *The Calculus of Observations* (1924), the chapters dealing with interpolation are published separately, as *A Short Course in Interpolation*. J. F. Steffensen, *Interpolation* (1927). See also Duncan C. Fraser, *Newton's Interpolation Formulas* (1927) and Isaac Newton, *Memorial volume* (1927). See also *CALCULUS OF DIFFERENCES*. (W. F. S.)

INTERPRETATION, in general, the action of explaining, or rendering the sense of an obscure form of words or an unknown tongue into a language comprehended by the person addressed. In legal use the word is employed in the sense of ascertaining the meaning of the language of a document. (See *CONTRACT*; *WILL*, etc.) It is usual for statutes to contain definitions and the British Interpretation Act of 1889 is of general application. This term is used similarly in the United States.

INTERREGNUM, strictly a period during which the normal constituted authority is in abeyance, and government is carried on by a temporary authority specially appointed (Lat. *inter*, between, and *regnum*, reign). Though originally and specifically confined to the sphere of sovereign authority, the term is commonly used by analogy in other connections for any suspension of authority, during which affairs are carried on by specially appointed persons. The term originated in Rome during the regal period when an *interrex* was appointed (traditionally by the senate) to carry on the government between the death of one king and the election of his successor (see *ROME: History*).

The most noteworthy use of the term "interregnum" in post-classical times is that of the Great Interregnum in German history between the death of Conrad IV. (1254) and the election of Rudolf of Habsburg (1273). See *GERMANY: History*.

INTERRUPTED CONTINUOUS WAVES, in radio, are waves obtained by the interruption at audio-frequency in a periodic manner of an otherwise continuous wave.

INTER-STATE COMMERCE includes the movement of passengers and freight from one State to another, and the agencies and facilities by which the transfer is accomplished; it comprises the mechanism and services of trade, transport and communication between citizens of different States. Broadly defined, the term commerce applies to a wide range of economic services, to ex-

change or distribution in general, but as here used it is limited to the traffic and trade that crosses State boundaries in the internal or domestic commerce of the United States. Foreign trade is not included, nor are communication agencies and services.

Inter-State commerce may be carried on by an individual or a partnership but it is for the most part conducted by corporations, which, like those concerned with production, tend to become larger, their activities being increasingly subject to regulation by the States and particularly by the Federal Government. In the interest of public safety the facilities employed by rail, highway, ocean and air carriers must conform to standards fixed by State and national laws whose enforcement is furthered by Government inspection of equipment of many kinds. Corporations must compete in inter-State commerce by methods that are "fair," and the accounts, finances, charges and services of carriers are comprehensively regulated by the national Government.

The principal agencies by which inter-State freight and passenger movements, or trade and travel, are effected, are the steam and electric railways, the vessels operated coastwise and on the Great Lakes, the rivers and canals, the carriers operating motor trucks and buses, and the aeroplanes. Carriers other than railroads subject to the Inter-State Commerce Act of 1887 as amended to date include pipe line companies (other than water companies), sleeping car, express, telegraph and telephone companies. Inter-State carriers by water are regulated in part by the Inter-State Commerce Commission, but mainly by the United Shipping board whose powers are defined by the Shipping Act of 1916 as amended and extended by the Merchant Marine Acts of 1920 and 1928. There is a Federal Trade Commission, created by the act of Sept. 26, 1914, to prevent unfair methods of competition in commerce. The Air Commerce Act of May 20, 1926, gives the secretary of commerce jurisdiction over inter-State air facilities and services.

Volume of Inter-State Commerce.—The volume of inter-State as distinct from intra-State commerce is not stated in official records, but it is well known that most goods shipped between points within the United States or sent to or received from foreign countries pass State boundaries. By far the larger share of the traffic of rail, water, highway and airway carriers being goods carried from one State to another, reference to the tonnage transported by these several carriers will indicate the magnitude of inter-State commerce in the United States.

During the year 1926, the railroads in the United States transported 1,439,427,824 tons of revenue freight, their service being equivalent to the movement of one ton nearly 447 billion miles, the number of tons having nearly doubled and the ton miles having more than doubled in 20 years. There were 13 tons and over 4,000 ton miles of railroad freight per inhabitant, and, as the average distance a ton was hauled was 311 m., it is evident that most of the traffic must have been inter-State.

The domestic water-borne commerce of the United States in 1926 moved coastwise and on the Great Lakes and other inland waterways totalled 405,210,902 short tons. Roughly two-fifths of the entire tonnage consists of coastwise domestic traffic, a somewhat smaller share moves on the rivers and canals, and between 20 and 25% is transported on the Great Lakes. The major portion of this large traffic was contributed by coal and coke and iron-ore, of which there is a heavy tonnage on the Great Lakes, by petroleum and its products which move coastwise in great volume, by lumber and logs, transported and rafted largely on the Pacific seaboard, and by such articles as sand, gravel and stone that are shipped locally on numerous inland waterways. The traffic on the rivers is of less relative importance than the tonnage would indicate because the average length of haul is much shorter than on the Great Lakes and along the seaboard. One cause that has contributed largely to the growth of coastwise commerce has been the Panama canal, through which in 1927 nearly 11,000,000 long tons of cargo moved between the two seaboard of the United States, the average length of haul being quite 5,000 nautical miles.

The American Automobile Association has stated that on Jan. 1, 1927, 2,468 common carrier motor buses were operated by 458 companies over 52,017 m. of inter-State routes. On the same date the total bus route mileage, inter-State and intra-State, was

given as 270,000 miles. The corresponding mileage over which motor trucks were operated in contract and common carrier services is not known, but it would doubtless be greater than the bus route mileage for intra-State and less for inter-State operations.

The bureau of public roads of the U.S. department of agriculture has conducted surveys in several States to determine the nature and volume of motor passenger and freight traffic. In a small State like Connecticut, with its dense population and highly diversified industries, and with the city of greater New York close by, there would be a large use of the highways, and it was found that 27.5% of the motor freight tonnage on the Connecticut highways was inter-State traffic. In the State of Texas, however, only 2.5% of the motor truck transportation is inter-State; and in Minnesota it was found that 99% of the motor truck operators did intra-State hauling exclusively.

Inter-State motor traffic is but a small share of the total, because the motor hauls are of short average length. In eight States studied by the united bureaux of public roads in 1925 it was found that over 50% of the suburban and inter-urban motor bus routes were less than 20 m. in length and nearly three-fourths were less than 30 m. long, only 11.9% being over 50 miles. Inter-State bus routes in these eight States had from 4 to 15% of the total mileage of all routes. Motor truck hauls are also of short average length, hauls of less than 30 m. comprising 58% of the total in California, 71% in Ohio and 80% in Pennsylvania.

Air transport routes are as characteristically long as motor routes are short, and most air services over regular routes are inter-State. Aeronautics is making rapid progress in the United States; but, with the exception of the air mail service in which greater development has been made than in any other country, the United States is surpassed by both Germany and France. Commercial air transport promises to be much larger in the United States in the near future. Its early development has been relatively slow, because it has not received Government subsidies, while European countries have given large aid to companies to enable them to maintain passenger and package air transport services.

In 1927 there were 433 commercial air service and transport companies and 1,000 aeroplanes in commercial services of different kinds. There were 23 companies constructing aeroplane engines and 66 building aeroplanes. Of the 433 commercial companies 300 were engaged in transporting passengers and freight for hire. The number of passengers carried during the year 1926 was 387,852, but many of these were taken on short rides and not over regular routes. The amount of freight transported was 792,678 pounds. This, however, was much less than the weight of merchandise carried either in France or Germany. On the contrary, air mail transport in the United States is well developed and is rapidly increasing. In 1928, aeroplanes were carrying mail 20,000 m. daily. On Sept. 1, 1927, the American Railway Express company began accepting packages for transmission by the air mail carriers with whom the company entered into contracts. Several large manufacturers are operating planes in connection with their business operations. The next step to be taken in the development of air transport is the operation of large passenger planes, probably in connection with the railroads, and the inauguration of regular common carrier services for the carriage of package freight of high value per bulk and weight. Such passenger and freight services, as well as those for the carriage of mail and express, will be mainly inter-State.

Freedom of Inter-State Commerce in the United States.—

The commerce passing State boundaries in the United States has become of great volume because there are no legal barriers. The United States throughout its wide territory is a single commercial unit with full freedom of internal trade. In this regard the United States is in marked contrast with Europe, where racial and historical causes have brought about the existence of many nations each of which is concerned with safeguarding its own internal trade against the undue encroachment of the commerce of other countries. Freedom of trade within a continental area richly endowed with natural resources has been of great assistance to the economic development of the United States.

Freedom of inter-State commerce has been as great an aid to

political success as to economic welfare. The commerce clause of the Constitution made a united country possible; in spite of sectional divergencies and a civil war over the issue of slavery, the nation has been held together and the States have grown into an indissoluble union because industry, trade, transport and communication have known nothing of State boundaries or of political differences. Government under the Articles of Confederation broke down not only because Congress had no power to levy taxes, but also because the central Government having no authority over commerce, each State sought to develop its domestic and foreign trade at the expense of the other States. Economic as well as political necessity forced the States to organize a commonwealth with nation-wide authority over trade.

Power of the United States Government over Inter-State Commerce.—The power "to regulate commerce with foreign nations, and among the several States" is vested in Congress by the Constitution which also stipulates that "No State shall, without the consent of the Congress, lay any imposts or duties on imports or exports, except what may be absolutely necessary for executing its inspection laws"; also that "No State shall, without the consent of the Congress, lay any duty on tonnage." The Constitution provides that Congress shall levy no tax or duty "on articles exported from any State," and that "No preference shall be given by any regulation of commerce or revenue to the ports of one State over those of another. Nor shall vessels bound to or from one State be obliged to enter, clear, or pay duties in another." These prohibitions in the Constitution prevent restrictive regulation of commerce while the positive power granted to Congress is comprehensive and has been so interpreted by Congress and the Supreme Court as to make regulation positive and constructive. In regulating, Congress can promote inter-State commerce, and that, to an increasing extent, has been the policy of the Federal Government.

The interpretation of the commerce clause of the Constitution, through a long series of Supreme Court decisions, has tended to narrow the powers of the States and to broaden those of the Federal Government over inter-State, and indirectly over intra-State commerce. Chief Justice Marshall laid a broad and secure foundation for Federal authority in 1824, in the case of *Gibbons v. Ogden* (9 Wheaton 1). In this classic decision, denying to the State of New York the power to grant to a steamboat company a monopoly of steam navigation in the waters of the State to the exclusion of others owning vessels licensed by the United States, the chief justice enunciated the principle that has guided the Supreme Court in all subsequent interpretations of the commerce clause when he said:—"By virtue of the comprehensive terms of the grant, the authority of Congress is at all times adequate to meet the varying exigencies that arise, and to protect the national interests by securing the freedom of inter-State commercial intercourse from local control."

The extension of the power of Congress over inter-State (and incidentally intra-State) commerce by legislation and court decisions has affected all four categories of commerce and carriers—commerce by waterways, railroads, highways and air.

Federal Regulation of Inter-State Shipping.—Among the Supreme Court decisions defining the boundaries of State and Federal power over shipping was *Simot v. Davenport* (22 Howard 227) which in 1860 held unconstitutional a law enacted by Alabama in 1854 requiring special State registration of all vessels navigating waterways in the State. The court ruled that a vessel enrolled by the United States cannot be compelled to secure State registration. Likewise in 1871 the Supreme Court annulled a law enacted by Alabama in 1866 imposing a tax of \$1.00 per ton on all vessels operating upon the navigable waters within the State. The States may tax ships as property, but may not levy a tonnage tax (*Cox v. the Collector*, 12 Wall. 204). A State is also without power to impose port wardens' fees upon ships entering its ports (*Steamship Company v. Port Wardens*, 6 Wall. 31, decided 1867), or to place an occupation tax on persons or corporations employing vessels in a manner authorized by a U.S. licence (*Moran v. New Orleans*, 112 U.S. 69, decided in 1884).

These Supreme Court decisions negated attempts of the States

to burden the facilities of commerce. The legislative policy of Federal regulation has been a positive one. Harbours have been improved and inland waterways have been canalized and extended; the Shipping Act of 1916 and the Merchant Marine Acts of 1920 and 1928 provide both for aiding and for regulating shipping. Moreover, the Inter-State Commerce Act, particularly as amended by the Transportation Act of 1920, empowers the Inter-State Commerce Commission to establish through routes and rates by railroads and waterways and thus to promote the use of waterways by making them a part of a co-ordinated system of rail and water lines for the service of inter-State commerce.

Regulation of Inter-State Commerce by Rail.—The main carriers of inter-State commerce in the United States are the railroads. The Federal regulation of railroads which began with the Inter-State Commerce Act of 1887 has been extended in scope by subsequent laws until it now applies comprehensively to all such carriers engaged in inter-State commerce. Moreover, inter-State and intra-State commerce and railroad services are so inter-related that the Federal Government in exercising its plenary power over inter-State commerce incidentally limits in large measure the regulation of intra-State trade and traffic by the States. The U.S. safety laws apply to all railroad equipment; railroad finances are regulated by the Inter-State Commerce Commission which must approve of the location and combination of proposed railroads and of the issue of securities; and the States may not establish intra-State rates that unreasonably discriminate against the inter-State charges fixed or authorized by the Federal Commission.

When the States began to regulate railroad rates, shortly after 1870, some of the States fixed rates on all railroad traffic including both that moving within and that crossing State boundaries, but in 1886 the U.S. Supreme Court in *Wabash v. Illinois* (118 U.S. 557) held that the States could not fix the rates on inter-State traffic. To do so would be to regulate inter-State commerce over which the United States has jurisdiction. For 25 years after this decision by the Supreme Court no question was raised as to the power of the States to fix rates on intra-State traffic that were *per se* reasonable, but in 1911 the Railroad Commission of Louisiana complained to the Inter-State Commerce Commission that the railroad rates fixed by the State authorities of Texas on traffic within that State were so much lower than the inter-State rates as to discriminate against traffic from Louisiana into Texas and to prevent Shreveport, La., from competing with Houston and Dallas for the trade of north-eastern Texas. The commission decided in favour of the complainant and ordered the railroads to cease the discrimination which they did by raising the rates that had been fixed by Texas. This order of the Inter-State Commerce Commission and this action of the carriers were sustained by the U.S. Supreme Court in 1914 in the so-called Shreveport decision (234 U.S. 342). The principle established by this decision was extended and strengthened in the Transportation Act of 1920 by which the Inter-State Commerce Commission was given authority to prescribe rates and fares to take the place of intra-State rates that the Commission has found to discriminate unjustly against inter-State or foreign commerce.

To carry out the rate-making provisions of the Transportation Act of 1920 and to enable the carriers to obtain a reasonable return on their property, the Inter-State Commerce Commission raised rates and fares on all railroad traffic, intra-State as well as inter-State. The State of Wisconsin had fixed passenger fares by statute at 2 cents a mile, and the Railroad Commission brought action in the Federal courts to test the power of the United States to substitute for those fares others fixed by the Inter-State Commerce Commission. The Supreme Court (257 U.S. 563) upheld the statute and the order of the Inter-State Commerce Commission. Likewise, on the same day that it handed down this decision, the Court, in *New York v. the United States* (257 U.S. 591), set aside a contract provision in the charter of the New York Central railroad which had limited the fare on the main line of that road between Albany and Buffalo to 2 cents a mile, the Court holding in effect that the State in requiring such a fare to be charged was unjustly discriminating against inter-State passenger traffic subject to a

charge of 3-6 cents per mile.

Federal Authority over Inter-State Commerce by Highways.—The U.S. Supreme Court, in a series of recent decisions, has defined the boundaries of State and Federal authority over highway carriers engaged in inter-State commerce, just as the powers of the States and the nation over commerce by railroads have been determined by judicial interpretation. In 1923 the State of Michigan enacted a law requiring all motor carriers for hire upon the roads of the State to secure a certificate from the public utilities commission. The act also provided that such motor carriers for hire should be common carriers subject to the laws applicable thereto and should be required to carry insurance or furnish an indemnity bond. A motor carrier engaged solely in inter-State transport on a contract basis contested the validity of the law and the U.S. Supreme Court held that "It is a burden on inter-State commerce to impose on plaintiff (a private inter-State carrier) the . . . liability of a common carrier, and the obligation of furnishing such indemnity bond" as conditions precedent to engaging in inter-State commerce. The Court also held that a State could not by legislative fiat convert a private carrier into a common carrier, "for that would be taking private property for public use without just compensation" (*Duke v. Public Utilities Commission*, 266 U.S. 570).

A man desiring to operate a common carrier bus line between Seattle, Wash., and Portland, Ore., was granted an authorizing certificate by Oregon, but was refused one by Washington. The director of public works in Oregon ruled that there was no need for another carrier and denied the petition because "under the laws of the State, the certificate may not be granted for any territory which is already being adequately served." The Supreme Court, however, held that the law was a regulation of inter-State commerce forbidden by the commerce clause of the Federal Constitution (*Buck v. Kuykendall*, 267 U.S. 307, March 2, 1925).

These and other decisions of the Federal courts have given effect to a general definition of the powers of the States and of the United States respectively, which were clearly stated by the Supreme Court as early as 1915 in the case of *Hendrick v. State of Maryland* (235 U.S. 610) when the Court declared that "In the absence of national legislation covering the subject, a State may rightfully prescribe uniform regulations necessary for the public safety and order in respect to the operation upon its highways of all motor vehicles—those moving in inter-State commerce as well as others. . . . The reasonableness of the State's action is always subject to inquiry in so far as it affects inter-State commerce, and in that regard it is likewise subordinate to the will of Congress."

The Air Commerce Act of 1926.—To encourage the development of commerce by air, Congress passed a comprehensive Air Commerce Act, approved on May 20, 1926. The regulation of inter-State and foreign air commerce and of the aircraft employed therein is vested in the secretary of commerce and an additional assistant secretary of commerce provided for by the act. All civil aircraft operated inter-State or to foreign countries must be registered and rated by the secretary of commerce, who must examine and license airmen and establish air traffic rules. Provisions are made for the co-operation of the postmaster general, the secretary of agriculture (through the weather bureau), and the secretary of war with the secretary of commerce in the establishment and equipment of air routes, and the creation of emergency landing fields and other facilities. The Government does not provide terminal landing fields or airports and does not operate aircraft of its own, other than military and naval aircraft, and the postmaster general contracts with private air transport companies for the carriage of mails. The most helpful assistance given to air commerce by the Federal Government is that made possible by the provision of the act of 1926 which authorizes the secretary of commerce "to designate and establish civil airways, and within the limits of available appropriations hereafter made by the Congress (1) to establish, operate and maintain along such airways all necessary air navigation facilities except airports; and (2) to chart such airways and arrange for publication of maps of such airways, utilizing the facilities and assistance of existing

agencies of the Government so far as practicable."

The States and municipalities are establishing landing fields and airports in large numbers and the Federal Government is adding to and extending the established air routes, equipping them with temporary landing fields, with signal lights and radio apparatus. Conditions favourable to a rapid future development of inter-State and foreign air commerce are being established.

Prohibition of Combinations in Restraint of Inter-State Commerce.—The Antitrust (Sherman) Act of July 2, 1890, as amended and strengthened by the Clayton Act of Oct. 15, 1914, makes illegal contracts or combinations in the form of trusts, or otherwise, in restraint of inter-State or foreign commerce. In 1896, in the case of the *United States v. Trans-Missouri Freight Association* (166 U.S. 290), the Supreme Court held that the law applied to all combinations in restraint of inter-State or foreign commerce, including those that had previously been considered reasonable under the common law. This literal interpretation of the law hampered the development of large-scale organization in the conduct of commerce until 1911, when, in the Standard Oil company case (*United States v. Standard Oil Co.*, 221 U.S. 1) the Supreme Court enunciated and applied the "rule of reason," the effect of which was to hold that the Sherman Act prohibits only such combinations and restraints as were illegal at common law. This decision was not satisfactory to those who favoured a stringent curb on combinations, and the Clayton Act was passed to define more specifically what combinations or restraints were prohibited and to extend the law more definitely to agreements made to fix prices for the purpose of lessening competition or creating monopoly. The act, however, exempted labour and agricultural organizations from the provisions of the antitrust laws. The Clayton Act did not, in fact, strengthen the Sherman Act of 1890, the general terminology of the original law having proved more comprehensive than the more specific definitions and specifications of the later act.

Railroad rate agreements and railroad consolidations, which by the decision of the Supreme Court in the Trans-Missouri Freight Association case in 1896 and the Northern Securities case in 1904 (*Northern Securities Co. v. United States*, 193 U.S. 197) had been brought under the prohibitions of the Antitrust Act, were, by the Transportation Act of 1920, made legal when approved by the Inter-State Commerce Commission.

Fair Competition in Inter-State Commerce.—In 1914, Congress enacted a law, approved on Sept. 26, "to create a Federal Trade Commission and to define its powers and duties." The purpose of the act was "to prevent persons, partnerships, or corporations, except banks, and common carriers subject to the acts to regulate commerce, from using unfair methods in commerce." The commission of five members is given ample powers of investigation. If the commission finds that methods of competition prohibited by law are being employed it may order the violator of the law to desist from such practices. If the order is not obeyed, the commission may apply to a U.S. circuit court of appeals to enforce the order. As the court has the power to affirm, modify or set aside the order, the Trade Commission is in reality more an investigating than a regulatory agency. It has, however, served a useful purpose, not only because it may proceed upon its own motion, but also for the reason that it may be called upon by the attorney-general to report upon the manner in which a corporation that has been found by a court to be violating the antitrust laws is carrying out the court's decree. The Trade Commission may also be directed by "the President or either house of Congress to investigate and report the facts relating to any alleged violation of the Antitrust Acts by any corporation."

By the so-called Webb Act, approved on April 10, 1918, Congress exempted from the provisions of the Sherman and Clayton Antitrust Acts "an association entered into solely for the purpose of engaging in export trade," provided such association does not restrain trade within the United States. Such associations are subject to the prohibitions against unfair methods of competition contained in the act creating the Federal Trade Commission. The association must file with that commission full information regarding its organization and shall furnish such data

concerning the conduct of its business as may be required by the commission, whose duty it is to inform the attorney-general of any violations of law by the association.

The U.S. domestic commerce, most of which is inter-State, is changing constantly with the evolution of industry and industrial processes, with the shifting of the major centres of production of the leading staples of manufacture, and with improvements in transport agencies and in methods of transport. Moreover, while commerce is increasing in volume, large-scale organization of business is more and more taking the place of small enterprises. For these reasons, inter-State commerce is the subject of frequent legislation and of an increasing measure of administrative regulation.

BIBLIOGRAPHY.—The statutes concerning the regulation of inter-state commerce by the United States may be found in convenient form in *Barnes' Federal Code 1919* and its *Cumulative Supplement 1919-1926*. The U.S. Supreme Court decisions referred to in the article contain a large amount of historical and economic information. The *Annual Reports of the Inter-State Commerce Commission*, and *The Census of Water Transportation: 1926*, compiled by the department of commerce, are to be consulted for statistics of the volume of domestic traffic by rail and water. See also E. R. Johnson, G. G. Huebner and G. Lloyd Wilson, *Principles of Transportation* (1928), which contains much information concerning railroad, highway, ocean and air traffic in the United States. (E. R. J.)

INTERSUBJECTIVE, in psychology, means that which pertains at once to a number of conscious beings. So whatever is experienced simultaneously by several minds is described as intersubjective experience; and whatever is valued in the same way by a number of persons is said to have intersubjective value. The term is more especially used in conjunction with the term intercourse (intersubjective intercourse) to denote the intercourse of several minds. J. Ward lays special stress on intersubjective intercourse as a potent factor in the development of the human mind.

See J. Ward, *Naturalism and Agnosticism* (1907), *Psychological Principles* (1920); R. Goldscheid, *Entwicklungswerttheorie* (1908).

INTERVAL, a space left between the component parts of a continuous series, a pause in continuous action, a period of time intervening between two other points of time. (Lat. *intervallum*, space between the palisades on a rampart [*vallum*], or between the rampart and the tents of the legionaries.) In military language "interval" is the lateral space between men or bodies of troops, measured from the flank of one body to the flank of the next. It is used in contradistinction to "distance," the space from front to rear. In medical language "interval" is used of the intervening periods between attacks of a disease, particularly of the periods of a normal condition of mind sometimes experienced by an insane person, a "lucid interval."

In music, an interval is the distance separating one note from another in respect of pitch. It is named according to the number of degrees of the scale, otherwise the number of alphabetical notes, included by the two notes which contribute it. Thus E to F, E to F sharp and E to F double sharp are all seconds because there are in each case two degrees of the scale included. Similarly E to G, E to G sharp and E sharp to G are all thirds because there are three alphabetical notes included in each case. It is obvious, however, that the actual intervals are not the same in these cases and additional qualifying terms are therefore employed. Thus E to F, E to F sharp and E to F double sharp are minor, major and augmented second respectively; while E sharp to G, E to G and E to G sharp are similarly diminished, minor and major thirds. Intervals beyond the 9th are regarded as repetitions and classed as compound. (See MUSIC.)

INTESTACY, in English law, applies to the case of a person who dies leaving property but no will or one which fails to operate. It is also applied under the Administration of Estates Act, 1925, to cases where a person dies leaving a will which does not dispose of all of his property; such a person is intestate so far as his undisposed property is concerned and the rules as to intestacy apply to this property.

Formerly the devolution of property where its owner died intestate depended upon whether such property was realty or personality. At common law the realty vested immediately on the

owner's death in his common law or customary heir while his personalty vested in the ordinary before the Probate Act of 1857 and after that act in the judge of the court of probate. This rule was modified by the Conveyancing Act of 1881, but the Transfer of Land Act, 1897, which enacted that fees simple should be administered by the personal representatives of the deceased owner did not affect this rule until the probate court appointed administrators of the real property of an intestate if vested in his heirs. Now, by the Administration Act of 1925, all that is changed; and on the death of a person absolutely intestate all his property, real and personal, vests in the judge of the court of probate until that judge appoints an administrator. It is to be remembered in this connection that a hereditary title of honour is, in law, realty but that modern legislation has no application to it and that it descends according to the old law of inheritance, *i.e.*, to the heir even notwithstanding any will of the deceased owner or any claim of creditors.

Until Jan. 1, 1926, on the death, intestate, of an owner of heritable estates in land, *i.e.*, estates in fee simple and estates in fee tail, his fee simple estates vested in his heir and his fee tail in the heir of his body. On the other hand his personalty vested, as before mentioned, in trust, after payment of his debts, for his next of kin according to the Statute of Distribution, 1670-71. The Administration of Estates Act, 1925, has, so far as England is concerned, abolished the whole law of inheritance. Henceforth an heir will take only as a person mentioned in the grant of an estate in land. The heir of the body of a deceased tenant in tail will take under this head, and when property is limited to a person and on his death to his heir, it will vest in his heir, notwithstanding his will, as the rule in *Shelley's case* has been abrogated. Subject to these limitations, on the death of an owner of real and personal property intestate all his estate vests in his administrators on their appointment by the court. They hold his real estate on a trust for sale; this and the personalty form a joint fund for the payment of his debts and subject thereto such fund is to be distributed among the persons entitled under that Act. If there are no such persons the fund goes to the Crown as *bona vacantia*.

By the Administration of Estates Act, 1925, not merely the law of inheritance but the ancient preference of the male over the female line is abolished. On the death of a spouse intestate if the other spouse survives he or she will be entitled absolutely to all the deceased's personal chattels, a first charge of £1,000 on the estate whether the deceased died childless or not and a life interest in half of the rest of the estate: if the deceased died childless the life interest is in the whole of the residue. Subject to this the whole estate is divided equally between the descendants of the deceased, grandchildren of deceased children taking equally their parent's share, no share of an infant to vest absolutely until the infant comes of age or marries. Meanwhile the infant's share is to be held in trust for him by the administrators who have power to apply the income for the infant's maintenance and half of his prospective share for his advancement. If there are no descendants then the estate is to go to the deceased's parents equally or, if one is dead, to the survivor. If there are no brothers or sisters of the whole blood those of the whole blood equally, descendants of a deceased brother or sister to any degree taking *per stirpes*, *i.e.*, by family, the interest which their deceased ancestor would, if he were alive, have taken *per capita*, *i.e.*, as an individual member of the inheriting class. If there are no brothers or sisters of the whole blood those of any of the half blood succeed in the same way and if there are none of them then the grandparents, or such as may be surviving, succeed. If there are no grandparents surviving the property both real and personal goes to the Crown as *bona vacantia*.

It will be well to notice that the Administration of Estates Act makes three great changes as to the devolution of property on death. First, the whole law of inheritance is abolished and all an intestate's property devolves beneficially on his statutory next of kin; secondly, representation of a deceased ancestor is inherited in the collateral line, and thirdly no relative beyond the grandparents and their descendants is entitled to claim as

next of kin.

Scotland.—In the law of Scotland heritage descends to the heirs-at-law while the free movable estate of the intestate is divided amongst the heirs *in mobilibus* who are the next of kin and those entitled to share in the succession under the Intestate Movable Succession Acts, 1855 to 1919. The heir of the heritable (*i.e.*, real) property, if one of the next of kin, must collate with the next of kin if he wishes to share in the movables. Proximity of kin is reckoned in the same order as in the case of inheritance. The Intestate Movable Succession Acts, among other changes, allow the issue of a predeceasing next of kin, not more remote than brothers and sisters, to come in the place of their parent in succession to an intestate; give the father of an intestate dying without issue one-half of the movable property in preference to brothers or sisters; and if the father be dead, a similar preference entitles the mother to succeed to the whole, failing the father and brothers and sisters; they admit brothers and sisters uterine in the absence of brothers and sisters german or consanguinean, also father and mother.

There are now rights of succession in both heritage and movables between a mother and her illegitimate issue under the Legitimacy Act, 1926, s. 9 (4).

United States.—The devolution of both real and personal property is governed in all States by statute. The American legislation at an early period disregarded the common law rules of inheritance that gave preference to the eldest male and to males over females, and was modelled upon the civil law rules of inheritance as set forth in the 118th Novell of Justinian and followed by the English statute of distributions governing the devolution of personal property. The distinction between real and personal property remains important inasmuch as in most States realty vests immediately upon the death of the intestate in his heirs, whereas the title to personalty vests in the administrator for benefit of the next of kin. Between the time of the intestate's death and the appointment of an administrator, title to the personalty remains in abeyance but relates back to the intestate's death upon the grant of letters of administration. Furthermore, the devolution of realty is governed by the law of the State where it is situated, but personalty descends according to the law of the deceased's domicile.

The different State statutes of distribution have infinite variations. The rights of the surviving spouse are uniformly favoured. Curtesy (*q.v.*) is generally abolished, though dower (*q.v.*) is widely retained, the widow generally being required to elect between dower and the right to such distributive share as she would be entitled to under the statutes. The right of representation is generally limited to lineal descendants or close collaterals, and except where representation is permitted, kindred of the degree nearest to the intestate succeed to the exclusion of those of more distant degree, degree of kindred being reckoned according to the civil law principles. When all the heirs are of an equal degree of consanguinity, they commonly take *per capita*, but where they stand in different degrees the more remote take only *per stirpes*. Such States as California, Louisiana, New Mexico and Texas, where the civil law of Spain was once in force, have retained many features of intestate succession peculiar to the civil law.

INTESTINAL OBSTRUCTION (ILEUS), in surgery, a condition in which the onward passage of the intestinal contents is prevented. It is often associated with strangulation of the gut, leading to gangrene, and with systemic poisoning due to the absorption of toxins, resulting from the changes in the intestinal wall. The sole availing treatment is surgical, and that at the earliest possible moment. Intestinal obstruction may be conveniently divided into acute and chronic.

Acute Intestinal Obstruction.—One of the most urgent of surgical emergencies. The following are its chief causes: (1) strangulation by bands or adhesions or through apertures; (2) volvulus; (3) acute intussusception; (4) congenital malformations of the intestines; (5) the impaction of foreign bodies. Acute obstruction is also the natural termination of chronic obstruction, and often accompanies appendicitis and hernia (*q.v.*).

(J. A. Sr.)

(J. WA.)

(J. M. LA.)

(1) *Strangulation by Bands or Adhesions or through Apertures.*—These bands may result from stretching of inflammatory adhesions left by a former peritonitis, and are commonly situated between different parts of the mesentery or between the mesentery and another organ such as the appendix. A loop of bowel passes under a short constricting band and cannot return, or if the band is long it may form a noose in which the bowel is strangled (fig. 1.)

A coil of intestine may also slip into a hole in the mesentery or omentum or find its way into a pouch of peritoneum, forming what is known as an internal hernia. The patient is abruptly seized with acute abdominal pain associated with collapse. The pain is usually referred to the umbilicus, but this is no guide to the situation of the lesion. Vomiting is persistent, and starts the earlier as the obstruction is higher in the intestinal tract. Ultimately it becomes faecal. There is no obvious tumour; constipation is present, the abdominal walls are flaccid at first, but if no relief is obtained become tender when peritonitis ensues. In cases not treated by operation the average duration is five to seven days, and death takes place from exhaustion or from toxæmia following peritonitis.

FIG. 1.—INTESTINE STRANGLED BY A BAND OF TISSUE

(2) *Volvulus* is a twisting of the gut usually preceded by chronic constipation. There are two chief varieties: (1) in which the bowel is twisted upon its mesenteric axis (fig. 2); (2) in which it is wound round another coil of intestine. The sigmoid flexure is the commonest seat for volvulus. When once present, plastic peritonitis fixes the coil in position and the blood supply becomes obstructed. The acute symptoms start abruptly and are those of internal strangulation, but the pain at first is more intermittent in type. There is usually early tenderness over the spot and constipation is absolute. Much distress is occasioned by abdominal distension from flatus, which develops with remarkable rapidity. The swelling is localized at first. Spontaneous natural cure is unknown, and without surgical interference death is inevitable.

FIG. 2.—BOWEL TWISTED UPON ITS MESENTERIC AXIS

(3) *Acute Intussusception* forms about 30% of all cases of intestinal obstruction, and is the most common variety found in children. More than 50% of the cases are found during the first ten years of life, and half that amount in babies under one year; the large preponderance is in males. By intussusception is meant an invagination or protrusion of a part of the intestine in the lumen of the intestine immediately below it; the lower part of the intestine may be said to have swallowed that immediately above it. The mesentery attached to the upper portion is necessarily dragged in with it. The condition may be seen by referring to the diagram (fig. 3). It is to the constriction of the vessels in the entering mesentery and later to their possible complete obstruction that are due the late serious phenomena of intussusception, e.g., gangrene or rupture of the gut. Peritonitis also ensues, and by the formation of adhesions between the serous coats of the entering and returning parts leads to irreducibility of the intussusception. Spontaneous reduction of the invagination sometimes occurs, but the common result is gangrene with perforation of the intestine and acute septic peritonitis. Occasionally when there is no perforation adherence takes place between the segments, and the gangrenous portion sloughs off and is discharged by the rectum. The cause of intussusception is said to be violent peristaltic action, however produced. Polypoid tumours or masses of worms, or masses of irritating ingesta, are said to lead to its occurrence. X. Dolore and R. Leriche, however, contend that the primary factor is congenital mobility of the

FIG. 3.—VAGINATION OF INTESTINE INTO PART BELOW

caecum, and that this explains why two-thirds of the cases occur in children less than one year old. Intussusception is met with in four chief situations: (a) the ileo-caecal, which is said to be the most frequent, constituting 44% of all cases (Treves); (b) the enteric variety, involving the small intestine; (c) the colic form; (d) the ileo-colic, the ileum being invaginated through the ileo-caecal valve. Intussusception may be acute or chronic, sometimes lasting intermittently for years. The acute form is the most common. In young children there is severe pain, at first paroxysmal but later continuous; vomiting is less early and less continuous than in strangulation by bands, and tenesmus, much straining and the passage of blood and mucus from the anus are common. Collapse soon supervenes. Early in the case the abdomen is but little distended, and in about half the cases a distinct tumour can be felt. Sometimes the invaginated gut presents at the anus. Chronic intussusception occurs more frequently in adults than in children; the symptoms may resemble chronic enteritis and be so indefinite that the nature of the illness remains undiagnosed until an acute attack supervenes, or the patient succumbs to the diarrhoea, vomiting and haemorrhage.

(4) *Congenital Malformations of the Intestines.*—Persistence of Meckel's diverticulum, a structure which passes between the navel and the middle of the ileum and represents the nutrient canal of the foetus, may act as a band. Cases have been recorded in which the small intestine ended in a blind pouch. Imperforate anus is a fairly frequent occurrence in young infants, but attention is usually called to the condition. Partial strictures of the intestine, if the stricture be not too narrow, may pass unnoticed for years, and final complete obstruction may result from a blockage of the stricture by some foreign substance such as a plug of hard faecal matter or a fruit stone.

(5) *Impacted Foreign Bodies.*—These are gall-stones, faecal concretions (enteroliths) and foreign bodies swallowed by accident or otherwise, though knives, coins, pipes, flints, etc., swallowed by jugglers, are known to have passed by rectum without injury. The caecum and duodenum are favourite situations for obstruction. Foreign bodies may remain weeks or months *in situ* before giving rise to serious symptoms. Their diagnosis has been much simplified since the introduction of the X-rays.

Chronic Intestinal Obstruction.—The causes of chronic obstruction are very numerous, and may be divided into the following groups: (1) intra-intestinal conditions, i.e., the impaction of foreign bodies and impaction of faeces; (2) affections of the intestinal wall such as stricture, new growths in the intestine, particularly those of a malignant type, adhesions or matting together of the intestines from peritonitis or kinking of the gut from disease of the mesenteric glands; (3) chronic intussusception; (4) compression of the bowel by a tumour or bands developing outside the intestine. Of these the commonest are malignant growths and faecal impaction.

The general symptoms of chronic obstruction are more or less alike. The patient is attacked with gradually increasing constipation, which may alternate with diarrhoea which is generally set up by the irritation of the retained faeces. In obstruction due to malignant growths low in the rectum the character of the motions is changed, they become scybalous, pipe-like or flattened. The abdomen becomes distended, and at intervals severe symptoms may supervene, consisting of pain and vomiting with complete constipation owing to some temporary complete obstruction. The attacks usually pass off, and relief may be obtained naturally or by the administration of a purgative, but they have a tendency to recur and in malignant disease to increase to complete obstruction. Finally a seizure may persist and take on all the characters of an acute attack, and death may supervene from exhaustion, perforation or peritonitis, unless immediately treated. When it arises from simple stricture no tumour is to be felt, but in malignant disease the tumour may frequently be palpated, unless during an acute attack, when the abdomen is much distended with gas.

(1) *Faecal Impaction* is not uncommon in adult females who have suffered from chronic constipation. The common seat of the blockage is in the colon, chiefly in the sigmoid flexure and in the

rectum, but it may occur in the caecum. The accumulation may form a doughy tumour, which in parts may be nodular and intensely hard. The causes are due to the state of the contents of the bowel itself, to congenital or acquired weakness and diminished expulsive power of the bowel, or to painful affections of the anus, fissures, piles and painful bladder affections. The acute symptoms are always preceded by a prolonged period of malaise; the breath is offensive and the tongue foul, and the temperature may be raised from the absorption of toxins. Faecal impaction requires the regular and repeated administration of large enemata, given through a long tube, together with the administration of calomel and belladonna. Large impacted masses in the rectum may be broken up and removed by a scoop.

(2) *Strictures of the Intestinal Wall*.—Simple strictures are infrequent, and are dealt with by the operation of lateral anastomosis. They follow dysenteric or tuberculous ulceration or the passage of gall-stones. Stricture due to carcinoma of the intestinal wall occurs usually in the old or middle-aged, and the symptoms come on insidiously. As soon as the condition is diagnosed an attempt should be made to remove the tumour if freely movable, or if this is not possible to afford relief by short-circuiting the intestine or by colotomy.

(3) *Chronic Intussusception* has been frequently mistaken in the diagnosis for rectal polypus, cancer, tuberculous peritonitis, etc. (Treves). If diagnosed it may be reduced by inflation with air, but frequently too many adhesions are present for this to be possible, and laparotomy with excision of the mass should be undertaken; the results are said to be very encouraging.

(4) *Compression of the Bowel* due to a tumour or bands external to the bowel may occasionally give rise to obstruction. An exploratory operation should be undertaken for the excision of the tumour, or the separation of adhesions and release of the bowel, or if the intestines are much matted together by peritonitis an intestinal anastomosis may give relief. Obstruction due to paralysis of the muscular coat of the intestine has been described (adynamic obstruction), but its existence is a subject of dispute. (H. L. He.)

INTESTINE, in anatomy, the lower part of the alimentary canal; in man and mammals divided into the small intestine, from the pylorus to the ileocaecal valve, and the large, reaching from the caecum and colon to the end of the rectum. The word is frequently applied to the whole of the alimentary canal in invertebrates. (See ALIMENTARY CANAL.)

INTOXICATION, poisoning, or the action of poisons, whether of drugs, bacterial products or other toxic substances, and hence the condition resulting from such poisoning, particularly the disorder of the nervous system produced by excessive drinking of alcohol. (See INEBRIETY and DRUNKENNESS.)

INTRANSIGENT, one whose attitude is that of an irreconcilable. The term is used chiefly of politicians of an advanced type; those in complete antagonism to the existing form of government; but is especially applied on the continent of Europe to members of legislatures holding extreme Radical views. The word is also used non-politically, in the sense of intractability and intolerance.

INTROIT: see PLAINSONG.

INTROSPECTION, in psychology, the process of examining the operations of one's own mind with a view to discovering the laws which govern psychic processes (Lat. *introspicere*, to look within). The introspective method has been adopted by psychologists from the earliest times, more especially by Hobbes, Locke, Berkeley, Hume, and English psychologists of the earlier school. It possesses the advantage that the individual has a more direct and fuller knowledge of his own mind than of any other mind, and is able therefore to observe its action more accurately under systematic tests. On the other hand it has the obvious weakness that in the total content of the psychic state under examination there must be taken into account the consciousness that the test is in progress. This consciousness necessarily arouses the attention, and may divert it to such an extent that the test as such has little value. Such psychological problems as those connected with the emotions and their physical concomitants are especially defective

in the introspective method; the fact that one is looking forward to a shock prepared in advance constitutes at once an abnormal psychic state, just as a nervous person's heart will beat faster when awaiting a doctor's diagnosis. The purely introspective method has of course always been supplemented by the comparison of similar psychic states in other persons, and in modern psychophysiology it is of comparatively minor importance.

See PSYCHOLOGY, ATTENTION, etc.; G. F. Stout's *Manual of Psychology* (1919).

INTUITION, a term employed in philosophy and in ordinary life in many different meanings, some of which indeed are not only different but opposite. To disentangle them all adequately would require a discussion of the philosophical conceptions which lie at their several bases. The salient points may be indicated as follows. The constant element in the meaning of the term is that of direct or immediate apprehension.

Difficulty of Definition.—The difficulties and differences arise from different views as to what really is apprehended directly, as distinguished from what only appears to be so apprehended. One thing all would probably be agreed upon, namely, that the term intuition excludes all inference, all discursive reasoning, which is an indirect rather than a direct mode of apprehension. For the rest, however, the views are very conflicting. Some would include under intuition both sense intuition (or sense perception), like seeing a patch of colour, and conceptual or intellectual intuition, like grasping that "things equal to the same thing are equal to one another." Some would restrict the term to sense intuition only, and exclude all intellectual or conceptual elements from it. And others, again, employ the term to denote a process that is hardly comparable with ordinary sense-perception or with ordinary intellectual intuition. This is true not only of certain mystics, but also of some philosophers. In ordinary life, moreover, the term is often used to cover beliefs or prejudices which one cannot justify or excuse. Now even if intuitions may need no justification, it is a flagrant fallacy to treat every unwarranted opinion as an intuition, not to say an inspiration.

In Spinoza's Philosophy.—In the history of modern philosophy the term intuition occupies a prominent position chiefly in the philosophy of Spinoza, in the moral philosophy of the so-called intuitionist or intuitionist school, and in the philosophy of Bergson. The intuitionist school of moral philosophy is dealt with in the articles ETHICS and ETHICS, HISTORY OF. So we need only add a few words about intuition in the thought of Spinoza and of Bergson. Spinoza distinguished three main grades of knowledge or cognition. The lowest is that which is merely empirical, and does not rise above sense-perception; the next higher stage is what may be called scientific knowledge, the knowledge acquired by careful reasoning about observed phenomena—at this stage knowledge is no longer confined to mere particulars, more or less in isolation from each other, but includes the laws which connect them and gives them a certain orderliness. At the highest stage human knowledge rises to the comprehension of the whole universe as one inter-connected, self-dependent system, a complete pattern, so to say, of which the laws discovered at the second stage are the continuous but single strands. This highest kind of knowledge Spinoza called "intuitive knowledge" (*scientia intuitiva*). It rises above empirical and scientific knowledge, but it grows out of them; they culminate in it. Spinoza did not want to deprecate either sense perception or ordinary conceptual activity when he set up "intuitive knowledge" as the goal of intellectual and spiritual endeavour.

In Bergson's Philosophy.—In the philosophy of Bergson the case is rather different. His stress on intuition is definitely a protest against what he conceives to be the excessive tribute usually paid to intellect, or intelligence, and to science as the ripest fruit of intelligence. Bergson's advocacy of the claims of intuition is one aspect of the growing recognition in recent decades of the part played by instinct, as contrasted with intelligence in human life. For Bergson intuition is simply "instinct that has become disinterested, self-conscious, capable of reflecting upon its object

and of enlarging it indefinitely." Intelligence, according to Bergson, has for its original function the construction and use of inorganic tools in the service of life. It is, therefore, most at home in the world of inert solids. Now, for the practical purpose of making tools it is convenient to treat material bodies as discrete units each divisible *ad libitum*. But when intelligence becomes theoretical, and seeks to explain life and thought as well as inert matter, then it leads astray. For it tends to treat all things as if they consisted of lifeless matter, and the whole of reality is reduced to a dead mechanism, for intelligence is unable to comprehend life.

This defect of intelligence must be made good by intuition, which as instinct is moulded on life, so that its procedure is organic, not mechanical. When the consciousness which slumbers in instinct awakes, when it is wound up into intuition instead of being wound off into action, it can reveal the most intimate secrets of life. Intuition leads us to the very inwardness of life as successfully as intelligence guides us into the secrets of matter. Human consciousness is predominantly intellectual. But man is not entirely lacking in intuition, which functions whenever our deepest interests are at stake. "On our personality, our liberty, on the place we occupy in the whole of nature, on our origin and, perhaps, also on our destiny, it throws a light feeble and vacillating, but which none the less pierces the darkness of the night in which the intellect leaves us." And it is the function of philosophy to seize, to expand, and unite these floating intuitions, and so to introduce us into the spiritual life. Still, intuition must not be divorced from intellection, nor philosophy from science. A philosophy which rises upon and above scientific foundations is a very different thing from mere mysticism.

Largely as the result of Bergson's stand against the exaggerated estimate of the conceptual or intellectual elements in human orientation, various other thinkers have voiced the claims of what has been called the non-rational elements in human knowledge. It is possible that the pretensions of some forms of rationalism need checking. But the non-rational is apt to be rather inarticulate, and it is easy for obscurity to harbour the irrational as well as the merely non-rational or merely non-conceptual. (See also KNOWLEDGE, THEORY OF; LOGIC; ETHICS).

See H. Bergson, *Introduction to Metaphysics* (1912) and *Creative Evolution* (1922); R. Müller-Freienfels, *Irrationalismus* (1922).

(A. Wo.)

INTUITIONISM: see INTUITION, ETHICS and ETHICS, HISTORY OF.

INULIN, in chemistry, a starch-like carbohydrate ($C_6H_{10}O_5$)_{6n}, known also as alantin, menyanthin, dahlin, synanthrin and sinistrin. It occurs in many plants of the large family *Compositae*, to which the elecampane (*Inula Helenium*) belongs; and forms a white tasteless powder, sparingly soluble in cold water, very soluble in hot water and insoluble in alcohol. It is coloured yellow by iodine, and reduces ammoniacal silver and gold solutions, but not Fehling's solution. Heated with water or dilute acids, it is converted into laevulose (*D*-fructose). (See CARBOHYDRATES.)

INVALID COOKERY. As the aim in invalid cookery is to build up bodily weakness and strengthen the tissues, light and nourishing food should be given that entails a minimum of effort for the digestive organs. Small, frequent meals should be the rule, and these ought to be served as daintily as possible to attract the eye of the patient. Hence, moulds and other receptacles used for invalid cookery should be small. Where possible, broiled or steamed food is best, as by these methods the maximum of nourishment is conserved. Never give fried food to invalids. The best invalid food for many serious cases is milk. Doctors' special orders should be followed accurately. As a general rule, unless otherwise ordered, a fever patient requires a fluid diet, mainly milk. Milk may be mixed with lime water or barley water, or peptonized powders are sometimes used for those patients who find difficulty in taking large quantities of plain milk, but allowance should be made for dilution.

Where "solids" are permitted, corn-starch, arrowroot, patent barley and egg jellies are recommended. Beef juice and meat extracts, though excellent in certain cases, should not be given to

patients suffering from rheumatic troubles. Diabetic cases are not generally allowed starch and sugar, but plenty of fats and proteid are required. Saccharine should be substituted for sugar and gluten and proteid breads are useful. Gastric patients generally need peptonized foods, and when convalescent they may take beef juice or light meats; e.g., chicken or lamb. In tuberculosis it is very necessary to give plenty of nourishing food, especially milk, fats and oils; e.g., cream, fat bacon, yolks of eggs, etc. Lemon and orange juice and thin barley water are useful invalid drinks. Where iced water is given great care should be taken that the ice is pure and well washed.

Barley water can be made either with uncooked chicken barley or cooked pearl barley; many doctors advise the former method. The barley water is needed for cleansing purposes. For this, wash 2 oz. of uncooked chicken barley, place in a jug and pour over it one pint of boiling water; allow to stand until cool and strain off the clear liquid. Serve with a slice of lemon. Ordinary barley water is prepared by boiling 2 oz. of washed pearl barley in one pint of water until quite soft. Strain off the liquid. Flavour with lemon and sweeten to taste.

Oatmeal gruel is made with patent groats, English fine oatmeal or Scotch meal; for infants the fine oatmeal or prepared groats is best. Mix one teaspoonful with a little cold water; stir in half a pint of cold water; boil for fifteen minutes stirring all the time to keep free from lumps; strain and mix with half the quantity of milk; reheat, and sweeten and flavour to taste.

(J. A. Sr.)

INVALIDITY PENSIONS. It is a generally accepted principle in almost all civilized countries that where an employed person becomes permanently incapacitated for work through sickness or accident he should receive from some source regular periodical payments with a view to preventing him from falling into destitution. Provision of this kind may be made in several different ways. In the case of persons employed by the State, local authorities, statutory undertakings or many establishments, provision is usually made under a superannuation scheme, towards the cost of which contributions are paid by the employer and ordinarily by the employees also. Where the incapacity is due to an accident or an industrial disease arising out of the worker's employment, the worker becomes entitled to relief under the laws relating to workmen's compensation. (See WORKMEN'S COMPENSATION.) It is, of course, also open to any individual employed person to make provision for himself by private insurance. There remains, however, a large residue not covered by any of these forms of provision and in most countries the State has assumed the responsibility of making provision against the risk of invalidity amongst the general body of workers who are not otherwise protected.

In Great Britain such provision was first made in 1911 as part of the scheme of national health insurance. (See NATIONAL INSURANCE: *Health*.) Under that scheme an insured person who is rendered incapable of work through sickness or physical or mental disability is entitled in the first instance to receive sickness benefit up to a maximum period of 26 weeks, and if incapacity continues beyond the end of that period he remains entitled to weekly payments at a reduced rate in the form of disablement benefit for so long as his incapacity continues, until he attains the age of 65, when the provisions of the old age pensions scheme become available.

Under the Blind Persons Act, 1920, a person who is so blind as to be unable to perform any work for which eyesight is essential is entitled to a pension at the age of 50 on the same conditions as are applicable to persons of 70 under the general scheme of non-contributory old age pensions. (See OLD AGE PENSIONS.)

In all countries except Great Britain, State provision against invalidity is made not in conjunction with the State scheme of sickness insurance but ordinarily in association with the scheme of old age pensions, or in some cases under an entirely independent scheme. The essential difference between the schemes in force in most European countries and the British scheme is that the former involve the conception of invalidity as a permanent physical condition requiring the minimum amount of supervision,

whereas under the latter the payments are subject to the furnishing at short intervals of proof of continued incapacity for work.

It is interesting to note that although several European countries had not, up to 1928, adopted general compulsory schemes of insurance against sickness, schemes of compulsory insurance against permanent invalidity were in operation in every country except Hungary, Norway, the Baltic States and parts of Switzerland. The schemes are ordinarily on a contributory basis, the cost being shared between employers, workers and the State. In some countries the schemes apply only to certain classes of workers, for example, in Austria, to miners and salaried employees only, and in Denmark, only to such persons as have voluntarily insured themselves against sickness.

German System.—The following short summary of the German scheme will give an indication of the general character of the schemes in operation in most European countries:

In Germany a scheme of insurance for invalidity and old age pensions for all manual workers was introduced in 1889 and a scheme for salaried workers in 1912. Under the former scheme the State contributes a fixed sum annually towards each pension, while under the latter it makes no contribution towards the pension but bears the whole cost of administration. The contributions are graded according to earnings and are shared equally between employers and employed. The amount of the pension also varies in accordance with earnings and with the number of contributions paid. An insured person is entitled to a pension if, after he has exhausted his title to sickness insurance benefit, that is to say after 26 weeks of incapacity, he remains incapable, owing to sickness or infirmity, of earning one-third of his usual wages. A small additional allowance is made in respect of each dependent child of the insured person. The attainment of age 65 is treated for the purposes of the scheme as equivalent to permanent invalidity, and pension is thereafter payable for life. The scheme is administered by insurance boards composed of Government officials and representatives of employers and insured persons. These boards have been pioneers in preventive and curative work and have provided sanatoria, hospitals and other institutions in which preventive and remedial treatment is given. Treatment in such institutions may in suitable cases be substituted for the invalidity pension.

In Australia a non-contributory scheme of invalidity pensions, of which the whole cost is met by the State, has been in operation since 1908. Up to 1928 no State scheme had been introduced in Canada, South Africa or New Zealand. In the United States also there is no public provision for insurance against invalidity.

(E. HA.)

INVAR, an alloy of nickel and steel, characterized by an extremely small coefficient of thermal expansion; it is specially useful in the construction of pendulums and of geodetic measuring apparatus, in fact, in all mechanical devices where it is an advantage to avoid temperature compensation. The name was chosen as expressing the invariability of its dimensions with heat. (See CLOCKS; GEODESY.)

INVARIABLE PLANE, in celestial mechanics (*q.v.*), that plane on which the sum of the moments of momentum of all the bodies which make up a system is a maximum. It derives its celebrity from the demonstration by Laplace that to whatever mutual actions all the bodies of a system may be subjected, the position of this plane remains invariable.

INVENTIONS AND DISCOVERIES. The act of invention, like many other human activities, is difficult to define precisely. The distinction often made between invention and discovery is not logically justifiable. For example, the great advance which primitive man made in the first use of pottery may be viewed either as the discovery of certain properties of burnt clay or as an invention in forming and hardening clayey materials into valuable utensils. As in this instance, most cases of inventive progress include both an element of discovery and an element of invention.

Definitions of the process of invention set up in the patent laws of most countries involve three fundamental ideas; novelty, utility and the ability of the device to work. With regard to the

third point, for example, the rules of the U.S. patent office require that an inventor prove, on demand, that his device is operable. This is why inventors of pretended "perpetual motion" machines are asked first to demonstrate a working model. But even in patent law, exactness of definition of invention is difficult as is witnessed by the continual stream of patent cases in the courts of most countries.

The history of invention begins before that of mankind. Many inventions have unquestionably been made by animals; for example, nests, a crude use of tools, the beginnings of language. It is probable, furthermore, that no distinction of kind can be drawn between the most modern inventions of man and very ancient animal "inventions" which have been crystallized into instincts like those of the ants or bees or in bodily devices like the flexible backbone of vertebrates, the force-pump heart or the warm blood of birds and mammals. It is customary and justifiable for evolutionists to speak of the "invention" of the backbone by some species of primitive worm which developed the ability to stiffen itself against the flowing water of ancient streams.

In the history of mankind as distinct from that of his more ancient animal ancestors, the most fundamental and useful inventions were made, undoubtedly, before recorded history. Many lists of the "world's greatest inventions" have been prepared, all widely different. The following list of seven has no unusual authority but is perhaps defensible.

Most important of all human inventions is probably the invention-discovery of the function of the seeds of plants, resulting in agriculture and in freeing mankind from dependence on accidental finds of food. Next in practical importance although perhaps first in time, was the discovery of how to control fire. Third was the invention of pottery. These three are prehistoric. Their combined effect was to free man in considerable degree from threats of immediate starvation. Fire made available (by cooking) some foods not previously edible. Pottery dishes made it possible to cook foods more successfully and to store them for hours or days; pottery may have been both the result and partially the cause of settled houses, for fragile dishes could not be carried on daily wanderings and pot-stored foods in cave or hut created an incentive to return to that same spot at nights. Two other inventions of great human importance seem to have been made in ancient Babylonia, or close by in Indo-Persia. One is the invention of writing; the other the invention of standards of measurement, weight, time and money.

Two other great inventions are modern ones: the germ theory of disease imagined by Pasteur and the invention of tinned food. The method of preserving food in tins or other containers is probably defensible as the greatest of all inventions in historic times. Its effect has been to relieve mankind of dependence upon the annual harvest, since food can be carried over from year to year, or upon the local food supply, since canned food can be imported. It has been said that modern canned food for his armies would have enabled Napoleon to conquer the world. It is impossible to date the invention of food preserving precisely or to ascribe it to any individual. Like many of the world's greatest inventions and discoveries, the art was developed gradually over many years and by many individuals. It is significant that of the seven inventions just suggested; seeds, fire, pottery, writing, standards, the germ theory and canning, all except Pasteur's discovery are hopelessly anonymous.

Other lists of this kind often include speech, the domestication of animals, the concept of medical treatment, the invention of weapons, the development of a form of government, the erection of buildings, and others. In each instance there seem definite reasons for assigning these to lesser rank. Whatever theory one accepts as to the origin of speech, there can be little doubt that it was a slow development, beginning even in animals and characterized by a long series of small inventions; a word here, a bit of grammar there, rather than by any definite inventive act. The same is true of the ideas of leadership and government—devices also familiar, in some degree, to man's animal cousins and probably to his ancestors.

Man's first rude huts probably grew naturally out of shelters

made accidentally by fallen branches or perhaps in imitation of animal nests and lairs, like the nests that orang-utans still make in trees. Weapons, in the form of sticks or hurled stones, were probably also ape possessions long before man. One human invention of real importance was, however, that of the chipping or grinding of flint to make a sharp edge—an invention probably made many times independently in prehistoric days. The bow and arrow, incomparably the cleverest invention of prehistoric weapon makers, is of unknown history. There is some reason to believe it Asiatic and perhaps as ancient as the post-Neanderthal type of man.

The domestication of animals is another development probably slow, accidental and mutual; for the animals first domesticated must have gained much more than they lost by association with man. It is far more probable, for example, that dogs first adopted man than that man singled out the wild dog for a companion. The idea that mankind itself could cure its bodily ills—the central idea of medicine—is inextricably entangled historically with the ideas of religion and of magic; indeed it can scarcely be said, even now, that any large percentage of mankind has real confidence in medical science as distinct from trusted, but mysterious, skill.

In addition to these items, prehistoric times must be credited with the beginnings of mechanics, hydraulics, metallurgy, navigation, chemistry and many other arts, including painting and sculpture, well known from the caves of France. To prehistoric mechanics we owe the lever, the wedge, the saw and probably the pulley and rope. That remarkable invention, the wheel, was probably conceived in Europe or in Asia Minor relatively late in prehistoric times, for the Asian migrants into North America who survived as the American Indians did not possess it. Among the most surprising facts in the history of invention is that this simple and useful idea seems never to have occurred to so large a fraction of the human race.

The first known examples of practical hydraulics are the irrigation canals of Babylonia, but it is probable that both canals and wells were known to still earlier Asian peoples for the same purpose. Well drilling for water might be given rank, indeed, as one of man's really great inventions, were it not that it probably came about naturally and accidentally through the cleaning and deepening of springs as the water receded in times of drought. Drainage, sewerage and internal water supply to houses seem to have been arts begun in Babylonia and reasonably well understood by the time of the great Cretan civilization of nearly four thousand years ago. It is probable that man's first iron was obtained from meteorites found on the ground; perhaps accidentally as a result of trying to chip flint weapons out of the hard, heavy mass. Copper holds rank as probably the first metal made by fire from its ores. Both the Egyptians and the Babylonians evidently understood the metallurgy of this metal more than six thousand years ago.

Among the items of prehistoric chemistry are glazes for pottery, fluxes for use in working gold and other metals, and some knowledge of opaque glass for beads; all of these were already highly developed at the time of the first recovered civilizations of Babylonia. Navigation, probably first discovered by the accident of floating on a log, seems to have developed independently and very differently at different places and times; as witness craft so diverse as the inflated skin boats of Asia, the American Indian canoe, the dug-out tree trunks of Africa and the Pacific Islands, and many others.

Last among great prehistoric inventions should be mentioned lamps and clothes, making man in some degree independent of darkness and cold. The adoption of clothing is so largely instinctive that it seems to have happened over and over again with almost every conceivable material and with infinite variety of custom. The origin of lamps is still uncertain, although the first form was undoubtedly a crude wick floating in a dish of oil and was probably invented by those unknown forerunners of the Babylonians to whom we also owe, it is believed, the knowledge of copper and of irrigation, the invention of writing and not improbably that of the wheel.

Within historic times, one interesting lost chapter of the his-

tory of invention is that of the beginnings of mechanism; of things like treadmills and waterwheels and pumps. The first definite records of such things go back to the Greek mechanicians of Alexandria, including Archimedes. However, the picture of mechanics and hydraulics in their day is already that of a well-developed science with a considerable history behind it. It is probable, too, that Greek miners were using stamping and grinding machines for ores several centuries earlier. Mechanical grist mills rotated by oxen, to replace the prehistoric mortar, devices to lift water for irrigation, primitive water clocks to measure time by the drip of fluid through a hole, are other candidates for the honour of the world's first mechanism. To decide between them is now impossible.

The present century is characterized by what is called technology; it is sometimes called the "machine age." This modern civilization, differing in many fundamentals from any previous period of world culture, may be said to depend upon five basic inventions and discoveries. First of these, both in time and in importance, is the discovery of the use of coal as fuel and the resulting invention of a practicable steam engine. The principle of the steam engine was known 17 centuries ago. What made it practicable was coal fuel. Second is the improvement of the metallurgy of iron and steel; the chief steps of this being the perfection of the blast furnace, of the Bessemer converter and of the modern rolling mill. Third is the development of electric power; beginning with the physical researches of Oersted, Ampere, Henry and Faraday and culminating in modern dynamos and motors. More recent developments of electricity promise to revolutionize this science and to make it much more useful to man, as a result of the perfection of vacuum-tube methods of handling electrons, such as are used in radio. The fourth basic invention which may be said to support modern technology is the internal combustion engine, with its application to automobiles, motor boats, aircraft and other vehicles. The fifth is cement. Some observers might add others to this list; for example, telephony, cheap aluminium, the aeroplane or printing. It may be objected, however, that these are adjuncts to modern technology and improvements produced by it in the advantages of life, rather than fundamentals which lie at modern civilization's roots.

One invention in a somewhat different field is defensible, however, as among the most fundamental and important of modern times. This is the invention of the joint-stock, limited-liability company, typified by the modern corporation. It would be possible to argue that no social device in human history has accomplished so successfully the divorce of business policies or industrial undertakings from the hazards of individual human lives. Another gain to be credited to the idea of corporate organization is perfected continuity of information and experience from one generation to another.

Calculations are often made of the percentage of modern wealth due to invention, discovery and technology, as distinct from the unaided efforts of man. The following table summarizes one such estimate, rough but perhaps approximately correct for the average annual earnings of the citizens of the United States. It should be noted, however, that in no case are these earnings due solely to invention or to its results. The growing ability of men to work together with each other (as is typified by the corporation) has become, in this modern world, one essential of the production of any income.

It is probably significant that among the activities shown in the table on p. 547, the one with the lowest percentage use of modern technology (fisheries) is the lowest in total earning capacity.

Since the beginning of the 20th century there has developed, chiefly in the United States, a system of invention and discovery which promises revolutionary results. This is what has been called "organized research." Large American corporations have established well-equipped laboratories staffed by engineers and scientific men of proved ability. The idea is that the co-operative effort of organized, well-equipped staffs of specialists will progress farther and faster in scientific research and in invention or discovery than is possible to the so-called "garret inventor" working alone with limited equipment and meagre funds.

Annual Income in the United States of America

Activity	Total annual income (added value)	Estimated percentage of annual income due to the use of technology	Total annual earnings of technology
	Thousand million of dollars	%	Thousand million of dollars
Farms	15.0	80	12.0
Forests	3.0	50	1.5
Fisheries2	10	.02
Mines	8.0	95	7.6
Transportation (including railways)	9.0	100	9.0
Manufactures	26.0	90	23.4
Commerce	30.0	85	25.5
Total	91.2	87.7 (average)	79.02

It is noteworthy that this idea of co-operative research has been tried twice before in human history; first by Aristotle under the patronage of Alexander; second by the Alexandrian school in Egypt under the auspices of the Ptolemies. Little of permanent value in the field can be credited to the efforts of Aristotle. The Alexandrian school has a better record, since it is probable that the discoveries of fundamental principles in geometry, mechanics, hydraulics and pneumatics together with significant advances in optics were accomplished by the Alexandrian group. It is still too soon to determine the value to the world of the renewal of co-operative research. The danger of mere "organized mediocrity" has been suggested. It remains to be seen whether it can be avoided as co-operative research laboratories grow older and perhaps lose inspiration. It is already certain, however, that such co-operative investigation is able to pay dividends of almost immediate utility and money to the individual corporations which use it.

The constituents of what might be called "inventive ability" have not yet been made clear by the psychologists. The mental processes of an inventor may be separated, perhaps into two superficially different methods. One is sometimes called the "Edisonian" method, because of its supposed employment by Thomas Alva Edison. This consists in trying all conceivable possibilities more or less at random. For example, when Edison desired a suitable filament for his electric lamp his procedure, it is said, was to test every thread-like or wire-like material which could be obtained. Thus was it discovered that carbonized bamboo fibre was a suitable material.

The other manifestation of the inventive process is what is loosely called the flash of genius; a sudden inspiration, apparently accidental, which provides the germ of the invention. Although the psychology of such inspiration is quite unknown, it may perhaps be suggested that, after all, the process does not differ so markedly from the first and seemingly more laborious method. It is conceivable that the conscious inspirational flash which solves the inventor's problem really results from long turning over in his mind of the characteristics of the desired invention.

In any inventive process, therefore, it is probable that the essential thing is the inventor's ability to put together, either actually or in imagination, facts the possible mutual relations of which are not obvious. If this be true, the mental processes of the inventor must be nearly the same as those of the author inventing fictional plots. In both cases there must be added, however, a saving salt of critical ability; enabling an author to select plot combinations which are reasonable and workable, and an inventor to select for physical trial the particular imagined combinations of ideas which are most apt to bring practical success. (E. E. F.)

INVENTORY, a detailed list, schedule or enumeration in writing, of goods and chattels, credits and debts, and sometimes also of lands and tenements.

(See also **BANKRUPTCY**; **EXECUTORS AND ADMINISTRATORS**; **STOCK-TAKING**.)

INVERARAY, royal burgh and county town of Argyllshire, Scotland. Pop. (1921) 490. It lies on the southern shore of a bay, where the river Aray enters Loch Fyne, 40 m. directly N.W. of Glasgow, and 85 m. by water. Near the church stands an obelisk in memory of the Campbells who were hanged, untried, for their share in the Argyll expedition of 1685 in connection with the duke of Monmouth's rebellion. The ancient market-cross is supposed to have been brought from Iona in 1472. The chief industry is the herring fishery. The town originally stood on the north side of the bay, clustering round an ancient baronial hold, but it was removed to its present site in the middle of the 18th century. Inveraray became a burgh of barony in 1472; and Charles I., while a prisoner in Carisbrooke castle, raised it to a royal burgh in 1648. Much has been done for it by the ducal house of Argyll, whose seat, Inveraray Castle, was built between 1744 and 1761 from designs by Robert Adam. The earls and dukes of Argyll were great planters of trees—mainly larch, spruce, silver fir and New England pines—and their estates around Inveraray are among the most finely wooded in the Highlands. Duniquoich, a timbered conical hill, adjoins the castle on the north.

INVERCARGILL, the chief town of Southland county, South Island, New Zealand, 139 m. by rail S.W. by W. from Dunedin. Pop. (1927) 22,590. It lies on a deep estuary of the south coast named New River Harbour, which receives several streams famous for trout-fishing. It is the centre of the large grazing and farming district of Southland; and has a number of factories, including breweries, foundries, woollen mills and timber-works. The plan of the town is rectangular, with wide streets; and there is a fine open reserve. The harbour is deep and well sheltered, but the greater part of the trade passes through the neighbouring Bluff Harbour, the port of call and departure for steamers for Melbourne and Hobart. Southland was a separate province between 1860 and 1870, but, failing financially as such, rejoined the parent province of Otago. The town is the regular starting-point of a journey to the famous lakes Wakatipu and Te Anau, which are approached by rail.

INVERCLYDE, BARON: see **BURNS, SIR GEORGE**.

INVERELL, a town of Gough county, New South Wales, Australia, on the Macintyre river, 341 m. N. of Sydney, with which it is connected by rail. Pop. (1926) 4,510. It is the centre of an agricultural district producing, chiefly, wheat and maize; the vine is also grown and excellent wine is made. There are silver, tin and diamond mines near the town. Inverell became a municipality in 1872.

INVERFORTH, ANDREW WEIR, 1ST BARON (1865–), British shipowner and administrator, was born at Kirkcaldy, Scotland, on April 24, 1865. He was educated at Kirkcaldy and afterwards adopted a business career, founding in 1885 the firm of Andrew Weir and Co., shipowners and merchants, of London and Glasgow. Having made a large fortune in business, in April 1917 Mr. Weir entered Lloyd George's government as surveyor-general of supply at the War Office, and held this post until Jan. 1919. The same year he was sworn of the privy council and raised to the peerage. He was minister of munitions and supply from Jan. 1919 to March 1921.

INVERNESS, royal burgh, seaport and county town, Inverness-shire, Scotland. Pop. (1921) 20,937. It lies on the Ness. It is an important railway centre, 118 m. N. of Perth by the L.M.S.R. Owing to its situation at the north-east of Glen More, the beauty of its environment and its fine buildings, it is held to be the capital of the Highlands; and in summer it is visited by many tourists. The present castle dates from 1835, and stands on the site of the ancient fortress, blown up by the Jacobites in 1746. Of the churches, the High or Parish church has a tower containing one of the bells which Cromwell removed from Fortrose cathedral. On the left bank of the river stands St. Andrew's Episcopal Cathedral, erected in 1866. Public buildings include a library and museum, with a collection of Jacobean relics, in Castle Wynd. In front of the Town Hall (1882) stands the Forbes memorial fountain, and near it is the old town cross of 1685; at the foot of the latter, protected since the great fire of 1411, is the famous stone called Clach-na-Cudain (Stone of

the Tubs), from its having served as a resting-place for women carrying water from the river. The old gaol spire, slightly twisted by the earthquake of 1816, serves as a belfry for the town clock.

Half a mile to the west of the Ness is the hill of Tomnahurich (Gaelic, "The Hill of the Fairies"). The open spaces include Victoria park; the Ness islands, connected by a bridge with the mainland; and the ground where the Northern Meeting—the most important athletic gathering in Scotland—is held.

Inverness is the great distributing centre for the Highlands, and the annual sheep and wool market is well known. Petroleum is the largest import. Its industries, however, are not extensive, and consist mainly of tweed manufactures, brewing, distilling, nurseries, saw-mills, granite works, an iron foundry and railway shops. There is some shipbuilding and a considerable trade with Aberdeen, Leith, London and the east coast generally. The Caledonian Canal passes within 1 m. of the town on its western side. In Muirtown Basin are wharves and at Clachnaharry the Canal enters Beaully firth. The harbour, formed by the mouth of the Ness, covers about three acres. There are piers and a breakwater at Kessock at the river mouth, with excellent anchorage and a slipway at the junction of the Ness with the Firth. The river at Inverness is crossed by four bridges and a railway viaduct.

Inverness was one of the chief strongholds of the Picts, and in 565 was visited by Columba with the intention of converting the Pictish king Brude, who is supposed to have resided in the vitrified fort on Craig Phadrick, 1½ m. W. of the town. The castle is said to have been built by Malcolm Canmore, after he had razed the castle in which Macbeth according to tradition murdered Duncan. William the Lion (d. 1214) granted the town four charters, by one of which it was created a royal burgh. Of the Dominican abbey founded by Alexander III. in 1233 hardly a trace remains. On his way to the battle of Harlaw in 1411 Donald of the Isles burned the town, and 16 years later James I. held a parliament in the castle to which the northern chieftains were summoned, of whom three were executed for asserting an independent sovereignty. The house in which Queen Mary lived in 1562, when denied admittance to the castle, stands in Bridge street. At the north end of the town Cromwell built a large fort, but with the exception of a portion of the ramparts it was demolished at the Restoration.

INVERNESS-SHIRE, highland county, Scotland, bounded north by Ross and Cromarty, and the Beaully and Moray firths, north-east by the shires of Nairn and Elgin, east by Banff and Aberdeen shires, south-east by Perthshire, south by Argyllshire and west by the Atlantic. It includes the Outer Hebrides south of the northern boundary of Harris, and several of the Inner Hebrides and is the largest shire in Scotland. Its area (excluding water) is 2,695,094 ac., of which more than one-third belongs to the islands. The county comprises the districts of Moidart, Arisaig and Morar in the south-west, Knoydart in the west, Lochaber in the south, Badenoch in the south-east and the Aird in the north. Excepting comparatively small and fertile tracts in the north on both sides of the river Ness, in several of the glens and on the shores of some of the sea lochs, the county is wild and mountainous and the scenery is very beautiful. There are more than 50 mountains exceeding 3,000 ft., among them Ben Nevis (4,406), the highest mountain in the British Isles, the extraordinary assemblage of peaks forming the Monadhliadh mountains in the south-east, Ben Alder (3,757) in the south, and the group of the Cairngorms on the confines of the shires of Aberdeen and Banff. Almost the whole mainland part of the county is occupied by the younger highland schists and metamorphic rocks, with many isolated patches of granite, of which the largest is on the eastern boundary, including Cairngorm. Athwart the county from south-west to north-east strikes Glen More, the Great Glen, or Glen More-nan-Albin, an old fault or line of earth-fracture along which displacements have occurred during more than one geological period. It contains Loch Lochy and Loch Ness, and through it was constructed the Caledonian canal (*q.v.*). Only in the north-east of the shire, and extending up Glen More midway along Loch Ness, does the Old Red Sandstone replace the typical highland rocks. (On the islands, *see* **HEBRIDES** and **SKYE**.)

Rivers and Lakes.—In the north-west the Beaully river (16 m.) is formed by the confluence of the Farrar and the Glass. The Enrick (18 m.), rising in Loch-nan-Eun falls into Loch Ness, just beyond Drumnadrochit. The Ness (7 m.), emerges from Loch Dochfour and enters the sea to the north of Inverness. The Moriston (19 m.) flows out of Loch Clunie and falls into Loch Ness 4 m. south of Mealfourvounie (2,284 feet). The Lochy (9 m.), issuing from the loch of that name, runs parallel with the Caledonian canal and enters Loch Linnhe at Fort William. The Spean (18 m.), flowing westwards from Loch Laggan, joins the Lochy as it leaves Loch Lochy. The Nevis (12 m.), rising at the back of Ben Nevis, enters Loch Linnhe at Fort William. The Leven (12 m.) drains a series of small lochs to the north-west of Rannoch, and the Dulnain (28 m.), rising in the Monadhliadh mountains, enters the Spey near Grantown, falling in its course nearly 2,000 ft. The Truim (15½ m.), rising close to the Perthshire frontier, flows into the Spey. Three of the larger rivers of Inverness-shire finish their course in other counties. These are the Spey, which for the first 60 m. of its course belongs to the shire; the Findhorn (70 m.), rising in the Monadhliadh mountains a few miles north-west of the source of the Dulnain; and the Nairn (38 m.), rising within a few miles of Loch Farraline. The two falls of Foyers are celebrated for their beauty, but their volume is affected, especially in drought, by the withdrawal of water for electric power works derived from the river Foyers. Other noted falls are Moral on the Enrick and Kilmorack on the Beaully.

There are many hill tarns and little lakes, considerably more than 200 being named. Loch Ness, the most beautiful and best known, is 22½ m. long, 1¼ m. broad at its widest point and 751 ft. deep. It is the largest body of fresh water in Great Britain, and forms part of the scheme of the Caledonian canal. Loch Oich (4 m. long) and Loch Lochy (9½ m.) also form portions of the canal. Loch Arkaig (12 m.) lies in the country of the Camerons, Achnacarry house, the seat of Lochiel, the chief of the clan, being situated on the river Arkaig near the point where it issues from the lake. The old castle was burnt down by the duke of Cumberland, but a few ruins remain. Loch Quoich (6 m.) lies north by west of Loch Arkaig, and Loch Garry (4½ m.) a few miles to the north-east; Loch Morar (11½ m. long by 1½ broad) is only about 600 yd. from the sea, to which it drains by the river Morar, which falls over a rocky barrier. The loch is 1,017 ft. deep and is thus the deepest in the United Kingdom. Loch Ericht, partly in Perthshire, is 14½ m. long and lies at a height of 1,153 ft., being thus the highest lake of such large size in Great Britain. It is finely situated in wild highland country at the foot of Ben Alder. Loch Laggan (7 m.) and Loch Treig (5½ m.) in the south are situated in the midst of natural forests. The principal salt-water lochs on the Atlantic seaboard are Loch Hourn ("Hell's Lake," so named from the wild precipices rising sheer from the water), running inland for 14 m. from the Sound of Sleat and separating Glenelg from Knoydart; and Loch Nevis (14 m.), a few miles farther south.

The parallel roads of Glen Roy, a glen with a north-easterly to south-westerly trend, a few miles east of Loch Lochy, presented a problem that long exercised geologists. At heights of 1,148 ft., 1,067 ft. and 835 ft., there run uninterruptedly along each side of the glen terraces of a width varying from 3 to 30 feet. They are now generally taken to be the gently sloping banks of lakes dammed up at different levels successively by glacier ice. Further evidences of glacial action are abundant in many places, in the form of roches montonnées, striations, moraines, etc. At several points on the coasts remains of old marine terraces are seen at 100 and 25 ft. above present sea-level.

Among the finer glens are Glen Urquhart and Glen Moriston to the west of Loch Ness, Glen Feshie in the east, and Glen Nevis at the southern base of Ben Nevis. Glen Garry, to the west of Loch Oich, gave its name to the well-known cap or "bonnet" worn both in the Highlands and Lowlands. In Glen Finnan, at the head of Loch Shiel, Prince Charles Edward raised his standard in 1745. The great straths or valleys are in the north and east, the chief among them being Strathfarrar, Strathglass and Strathnairn, and the heads of Strathearn and Strathspey.

History.—To the north of the boundary hills of the present counties of Argyll and Perth (beyond which the Romans attempted no occupation) the country was occupied in Roman times by the Picts. The territory was afterwards called the province of Moray, and extended from the Spey and Loch Lochy to Caithness. These limits it retained until the 17th century, when Caithness (in 1617), Sutherland (in 1633) and Ross-shire (in 1661) were successively detached. Towards the end of the 6th century Columba undertook the conversion of the Picts, himself baptizing their king, Brude, at Inverness; but paganism died hard and tribal wars prevented progress. In the 11th century, after the death of Duncan, Scotland was divided between Macbeth and the Norwegian leader Thorfinn, who took for his share the land peopled by the northern Picts. Malcolm Canmore, avenging his father, defeated and slew Macbeth (1057), and at a later date reduced the country and annexed it to the kingdom of Scotland. Insurrections continued until the reign of David I., when colonists of noble birth were settled in various parts of the shire. After the battle of Largs (1263) the Norse yoke was thrown off. In 1300 Edward I.'s expedition to Scotland passed through the northern districts, his army laying siege to Urquhart and Beaufort castles. After the plantation the clan system gradually developed and attained in the shire its fullest power, the chief being the Frasers, Chisholms, Grants, Camerons, Chattan, Macdonalds of the Isles, Clanranald Macdonalds and Macleods. The clans were constantly fighting each other, or their sovereigns.

In many quarters the Protestant movement made no headway, the clansmen remaining steadfast to the older creed. At the era of the Covenant, Montrose conducted a campaign in the interests of the royalists, gaining a brilliant victory at Inverlochry (1645), but the effects of his crusade were speedily neutralized by the equally masterly strategy of Cromwell. Next Episcopacy appeared to be securing a foothold, until Viscount Dundee fell at Killiecrankie, that battle being followed by a defeat of the Highlanders at Cromdale in 1690. The futile rising headed by Mar in 1715 led to a combined effort to hold the clans in check. Forts were constructed at Inverness, Kilchumin (Fort Augustus) and Kilmallie (Fort William); Wade's famous roads—exhibiting at many points notable examples of engineering—enabled the king's soldiers rapidly to scour the country, and general disarming was required.

Prince Charles Edward's attempt in 1745 had the effect of bringing most of the clans together for a while; but the clan system was broken up after his failure and escape. Heritable jurisdictions were abolished. Even the wearing of the Highland dress was proscribed. The effects of this policy were soon evident. Many of the chieftains became embarrassed, their estates were sold, and the glensfolk, impoverished but high-spirited, sought homes in Canada and the United States. As time passed and passion abated, a proposal to raise several Highland regiments for the British army was entertained with surprising favour, among the regiments then enrolled being the 79th Cameron Highlanders. Fort George, afterward the depot of the Seaforth Highlanders, 12 m. N.E. of Inverness, was begun in 1748.

Stone axes and other weapons or tools have been dug up in the peat, and prehistoric jewellery has also been found. Lake dwellings occur in Loch Lundy in Glengarry and on Loch Beaully, and stone circles are numerous, as at Inches, Clava, and in the valley of the Ness. Pictish towers or brochs are met with in Glenbeg (Glenelg), and duns (forts) in the Aird and to the west and south-west of Beaully and elsewhere. Among vitrified forts the principal are those on Craig Phadrick, Dundbhairdghall in Glen Nevis, Dun Fionn or Fingal's fort on the Beaully, near Kilmorack, Achterawe in Glengarry and in Arisaig.

Forests and Fauna.—Deer forests occupy an enormous area, particularly in the west, in the centre, in the south and south-east and in Skye. From the number of trees found in peat bogs, the county must once have been thickly covered with wood. Strathspey is still celebrated for its forests, and the natural woods on Loch Arkaig, in Glen Garry, Glen Moriston, Strathglass and Strathfarrar, and at the head of Loch Sheil, are extensive. Part of the ancient Caledonian forest extends for several miles near the Perthshire boundary. Many of the rivers and several of the

lochs abound with salmon and trout, the salmon fisheries of the Beaully, Ness and Lochy yielding a substantial return.

Agriculture.—The percentage of land under crops is small, and almost half the total area is mountain and heath. The Aird and Beaully districts, some of the straths and several of the glens are fertile. Oats are the predominant crop, barley is grown (mostly for the distilleries), but the wheat acreage is trifling. Turnips and potatoes are grown. About one-third of the holdings are crofts of five acres or under, and only about one-seventh of the holdings are over 30 acres. The operations of the Crofters' Commission (1886) have been beneficial in improving the condition of the people. The hills furnish good pastures. The flocks of sheep are heavy, the chief varieties on the uplands being Cheviots and black-faced and in some of the lower districts Leicesters and half-breeds. Of the cattle the principal breed is the Highland, the largest and best herds of which are in the Western Isles. Poiled and Short-horns are also reared, and Ayrshires are kept for dairy purposes. Highland ponies are raised on the hill farms.

Industries.—Excepting the industries carried on in Inverness, these are almost entirely confined to distilling—at Fort William, Carbost, Muir of Ord and some other places—brewing, wool and flax spinning, milling and (near Inverness) artificial manures. The catering for the wants of sportsmen and tourists, however, provides employment for many. The fisheries are of great value, especially at Fort William and in the Hebrides. Schemes to develop the industrial use of water power are in progress near Fort William.

Communications.—Rail communication in the shire is somewhat restricted, but the L.M.S. railway enters the shire from the south near Dalwhinnie and runs to Inverness via Aviemore and Daviot. Another portion of the same system also reaches the county town from Nairnshire. The Dingwall and Skye railway passes along the southern shore of Beaully Firth. In the south-west the L.N.E. railway enters the county 2 m. N.W. of Rannoch station and terminates at Mallaig, via Fort William and Banavie, sending off at Spean Bridge a branch to Fort Augustus. There is also communication by steamer from Glasgow with the piers of the Caledonian canal and with the Western Isles. Considerable shipping reaches Beaully and Inverness by way of Moray Firth.

Population and Government.—The population was 82,455 in 1921, when 35,449 persons spoke Gaelic and English, and 4,443 Gaelic only. The only considerable towns are Inverness (pop. in 1921, 20,937) and Fort William (1,913). The county returns three members to parliament with Ross and Cromarty. Inverness forms a sheriffdom, with resident sheriffs-substitute at Inverness, Fort William, and Portree, and is under school-board jurisdiction.

INVERSION, a term used in the study of geometric figures. To take a simple case, suppose in this figure

that $OP=1$, $OP_1=\frac{1}{2}$, and $OP_2=2$. Then $OP_1 \cdot OP_2 = OP$. Let us say that $OP=k$. Then it is evident that there is an infinite number of points P_1, P_2 on the line such that $OP_1 \cdot OP_2 = k$. A geometric transformation which replaces each point P_1 by a point P_2 such that $OP_1 \cdot OP_2 = k$ is called an *inversion*. In such case O is the *centre of inversion* and k is the *radius of inversion*. As P_1 moves nearer to O , P_2 moves farther away. As P_1 approaches P , P_2 also approaches P . In general we say that, when $xy=k$, x and y are inversely proportional, one decreasing as the other increases. We may also say that if $y=f(x)$, we may inversely consider x as a function (implicit) of y .

INVERTEBRATA, a term commonly used in zoology to denote all those animals not possessing a backbone (e.g., insects, snails, worms), in contradistinction to the Vertebrata (*q.v.*), in which a backbone, or some structure representing it, is present. The animals thus brigaded together do not form in any sense a natural assemblage, but the term is none the less a very convenient one. For the purposes of this dichotomous division the Protochordata (*Amphioxus*, *Balanoglossus* and the Tunicata, *qq.v.*) are included in the Vertebrata, though they have no true vertebral

column. (See ZOOLOGY, ZOOLOGICAL NOMENCLATURE, INVERTEBRATE EMBRYOLOGY.)

INVERTEBRATE EMBRYOLOGY. The word embryology means literally the science of the fruit of the womb (Greek *ἐμβρυον*), but in practice its meaning is extended to embrace all forms of individual development or life-history, whether that development takes place within the mother's womb, as in a human being, within a shell, as with a chicken, or freely in the open, like the frog tadpole.

The term invertebrate is a comprehensive one which includes all animals that are not vertebrates. There are two grades of animals, *viz.*, the Protozoa and the Metazoa. The first consist either of single cells, or of small masses of protoplasm with numerous nuclei, but not divided into cells, or, finally, of small groups of similar cells connected with one another, all of which are similar to one another and which carry out the same functions in the animal. When the animal reproduces they all take part in this act, so that the mother disappears in giving rise to her offspring. The bodies of the Metazoa, on the other hand, are composed of cells which are not all alike, but which are differentiated into sheets called *tissues*, which have different tasks to fulfil in the economy of the animal. When reproduction takes place this is carried out only by some of the cells, and so a distinction is made between the "germ-cells," which undergo development and give rise to new individuals, and the "soma" or body which carries out the other functions, such as digestion, movement, excretion, etc., and which shelters and nourishes the germ.

The life-history of the Protozoa (*q.v.*) exhibits essentially the same phenomena as that of the Metazoa, but for practical considerations it is not included in an account of the embryology of the Invertebrata. The Metazoa include about 16 distinct groups of animals, termed "phyla" (Greek *φυλον*, race). One of these phyla consists of the Vertebrata or back-boned animals to which we ourselves belong; all the rest are called Invertebrata.

The invertebrate phyla are (1) the sponges (Porifera, *q.v.*), (2) the sea-anemones, corals, polyps and jelly-fish (Coelenterata, *q.v.*), (3) the flat-worms (Platyhelminthes, *q.v.*), (4) the proboscis-worms (Nemertea), (5) the thread-worms (Nematoda, *q.v.*), (6) the arrow-worms (Chaetognatha, *q.v.*), (7) the segmented worms (Annelida, *q.v.*), (8) the articulates or jointed-legs (Arthropoda, *q.v.*), (9) the shell-fish and cuttle-fish (Mollusca, *q.v.*), (10) the spiny-skinned radiates (Echinodermata, *q.v.*), (11) the wheel-animalcules (Rotifera, *q.v.*), (12) the moss-animals (Polyzoa, *q.v.*), (13) the foot-axis animals (Podaxonia), (14) the lamp-shells (Brachiopoda, *q.v.*) and (15) the Entero-pneusta (*q.v.*), worms, breathing by slits in the wall of the gut, which constitute a bridge between the Invertebrata and the Vertebrata.

The reproduction of the invertebrate Metazoa takes place by two methods,—by budding or fission and by sexual germ-cells or gametes. Owing to considerations of space we can only consider reproduction by germ-cells.

The gametes are of two kinds, termed male and female, which normally must unite with one another before development is possible. The male cells are produced by a special type of individual called a male, the female cells by another type, the female. Occasionally both are formed in the same individual, which is then termed a *hermaphrodite*. The product of the union of a male and a female gamete is a *zygote*. The general structure of these cells is remarkably constant throughout the whole range of the Metazoa, from the sponges up to man himself. The female cell, the egg or *ovum*, has stored in its protoplasm deposits of reserve material or *yolk*, which enable the zygote to carry on its existence till it is able to obtain food from the outside.

These deposits vary enormously in bulk and bear little or no relation to the size of the future organism, but solely to the time which must elapse before food is available from outside, and the amount of the deposit regulates the size of the egg. Thus the egg of a woman is only $\frac{1}{125}$ in. in diameter, whereas that of a hen (termed "the yolk") is, as we all know, the size of a golf-ball. When an egg has very little yolk it is termed *alecithal*. When there is a good deal of yolk massed towards one pole the

egg is said to be *telolecithal*; when the yolk is in the centre surrounded by a skin of protoplasm, the egg is called *centrolecithal*. The Echinodermata (star-fish, sea-urchins, etc.) have, with few exceptions, alecithal eggs; the eggs of Mollusca (snails, clams and cuttle-fish) are telolecithal, whilst those of Arthropoda (crabs, spiders, insects, etc.) are centrolecithal.

The male gamete, the *sperm* or *spermatozoon*, is, when young, a simple rounded cell indistinguishable from a young female cell, but as it grows and ripens it undergoes remarkable changes. A vibratile filament termed the *tail* grows out from close beside the nucleus; the nucleus shrinks, expelling the nuclear sap and becomes converted into a small dense mass, termed the *head*, and the whole of the protoplasm is then sloughed off. The sperm, in virtue of the possession of a tail, is endowed with the power of locomotion; its task is to seek the female cell and to unite with it. When the head touches the surface of an egg the screw-like motion of the tail drives it in. As soon, however, as it is immersed in the protoplasm of the egg, the egg reacts by producing a membrane at its surface termed the *vitelline membrane*, which may be regarded as the primitive egg-shell, within which the zygote completes the first stages of its development. This membrane, in most cases, cuts off the tail of the spermatozoon, and in all cases prevents more spermatozoa from entering, so that all the potencies of the father who produces the male germ-cell are conveyed into the egg by a single nucleus, a fact which has a most important bearing on theories of heredity (*q.v.*). Once inside the egg, the spermatozoon head absorbs fluid and swells up to form a normal nucleus. (See CYTOLOGY.) The two nuclei now approach one another and become placed side by side to form the compound nucleus of the fertilized egg or zygote. In some cases the two components, male and female, can be distinguished from one another in the zygote nucleus during the first divisions of the egg, and it is then seen that the plane of division always cuts male and female portions of the nucleus symmetrically, so that equal portions of paternal and maternal nuclear substance are distributed to each daughter-cell. (See REPRODUCTION.)

Both the eggs and the male cells in all Metazoa divide twice during the process of ripening; these divisions in the male-cell give rise to four equal spermatids, all of which develop into spermatozoa, but in the case of the female germ cell they give rise to the ripe egg and to three minute vestigial cells termed *polar bodies*. The polar bodies, or at least one of them, adheres to the egg for some time, and the area to which they cling is known as the *animal pole* of the egg; the opposite pole towards which yolk is massed is known as the *vegetative pole*. In small and moderate-sized eggs the spermatozoon enters at the vegetative pole and makes its way upwards towards the female nucleus, which descends to meet it after having divided to form the second polar body; the path taken by the entering sperm seems to fix the future median plane of symmetry of the embryo.

There are two phases of development, such as are exemplified by the unhatched chick and the frog tadpole: they are termed respectively the *embryonic* and the *larval* phases. In the embryonic phase, the young organism is protected from the outside world by an egg-shell or within the womb of the mother and derives its nourishment either from stores of yolk or from the mother's womb. In the larval phase on the other hand, the young animal moves freely about and has to escape from its enemies and obtain its food by its own efforts. In every life-history there is both an embryonic and a larval phase; for no egg is ever thrust out naked into the world. Every one during the earliest part of development, as we have already seen, is protected by a vitelline membrane; and no animal is hatched exactly like the adult parent. Every animal undergoes a shorter or longer period of growth after birth during which it changes its shape and proportions and this part of its life-history may justly be called a larval phase. The first question to be settled is how these two phases are related to one another—which is the primary and which is the derived one?

A comparison with one another of allied species leaves no doubt that the larval phase is generally the primary mode of development and that the embryo is usually merely a concealed

and modified larva. This could be proved by instances selected from any invertebrate phylum, but more familiar cases are seen amongst the vertebrates. Everyone is acquainted with the tadpole larva of frogs and toads, and with its fish-like organs adapted to its life in water. The tadpole has three feather-like gills projecting from the head on each side, and between these gill-clefts, reaching into the throat, it has a flattened tail fringed with a fin. Now, in the West Indies there is a tree-frog, *Hylodes*, which lays its eggs far from water. From these eggs there emerge, not tadpoles, but froglings ready to take up their life on land. Nevertheless, if the covering of the egg be dissected off half way through development there will be found inside it a tadpole with gills and tail. These organs have no meaning in the embryonic life—they can be explained only if we assume that the embryo was formerly a larva.

We are now faced with the question, what is the meaning of the larval phase? If we base our reasoning on a broad comparative view, we shall be driven to the conclusion that the larva is a recapitulation of a former adult condition of the race. We find amongst the invertebrate phyla a typical anatomical structure common to the overwhelming majority of the members of each group, but there is always a minority of species with aberrant structure. When we examine the young stages of these aberrant members, *i.e.*, their latest larval phases, we find that during this period of their life they possess the typical structure of the group. As no comparative anatomist doubts for a moment that the aberrant members have been derived from more typical ancestors, this means that these aberrant forms in their later development repeat or recapitulate the history of the race. A good example of this phenomenon can be found amongst the oar-footed Crustacea (Copepoda). Certain species such as *Achtheres* attach themselves to the gills of fish and nourish themselves by sucking the blood. These develop into shapeless maggots devoid of limbs—except the third pair of jaws with which the copepod clasps the gill-filament of the host. But when first hatched from the egg, *Achtheres* is a free-swimming copepod with a typical head, thorax and abdomen and two pairs of swimming legs. In such cases, where the immediate ancestry of the species is clear and undisputed, the meaning of the larval phase is also quite clear, and we are therefore justified in adopting the same explanation for earlier larval stages, corresponding to which living adult forms embodied in other species are no longer to be found. Behind the first larval stage we come to the embryonic stages, to which a similar explanation must be applied, and so we are led back step by step to the fertilized unsegmented ovum, which on this interpretation represents the original unicellular protozoon from which all the higher animals are descended.

But if the whole course of development is thus to be regarded as a series of superposed recapitulations, these are by no means close and accurate reproductions of the ancestral history which they represent. Like human memories, they have suffered blurring and distortion, and like human memories also, the earliest

ones have suffered most, and we shall presently study the principal influences which have brought about this distortion. But since the life-history of every species in the same phylum is a separate edition of the same history, and since the distorting influences vary from species to species, by the aid of a truly comparative embryology we can eliminate most of these secondary alterations from the primitive history and thus restore—not in minute detail, but in broad outline—the general course of the development of animal life on the earth.

We have seen that the primary type of development is generally the larval, and that the essential nature of the larva is to be active. All its organs are functional—its nature is expressed by its habits. *Therefore a larval stage is a recapitulation of a former series of habits* which the ancestors of the present race possessed; and the passage to the present state of affairs, the last stage in evolution, was a change of habits.

The recapitulation of ancient habits in the earlier stages of the life-history therefore means that the change to modern habits took place when the animal had reached a certain size, but when it was still capable of growth and modification. The new habits, by causing the animal to use some of its organs more and others less, produced alterations in its structure through the stimulation of the growth of the more used organs and the inhibition of the growth of the less used ones; these alterations in succeeding generations were produced more and more easily and on slighter stimuli; in a word, the tendency to produce them became more deeply ingrained in the organism, till finally—as in the embryonic phase—they supervened without any external stimulus at all. As the new habits prove more advantageous in getting food and promoting growth, the change from larva to adult comes on at earlier and earlier periods of growth, and so the larva is usually very small compared to the adult. But occasionally the reverse change has taken place—the adult phase has become more dangerous, and serves not for feeding and growth, but chiefly for mating. In this case the larval stage may be more and more prolonged and the full-grown larva may be actually larger than the adult; this is the case with most moths and butterflies. In the case of certain salamanders such as the axolotl, the same change has taken place, and here the adult phase under ordinary circumstances is suppressed altogether; the animal mates and lays its eggs whilst still a larva. By exposing such animals to abnormal conditions, however, the lost adult phase may be brought to light. (See METAMORPHOSIS: *Experimental*.)

The larva is very small compared to the ancestral stage which it represents. For instance, organs repeated in series which act together and form a physiological unit, are represented in the larva by shortened series—sometimes organs which are in pairs are represented only by one. Thus the larva of *Achtheres* has *two* pairs of swimming limbs, whereas the normal copepod has *four* pairs. Occasionally the normal type of environment to which the larval organs are adapted has been changed. This difficulty may be met in two ways; either the larval phase is transformed into an embryonic one—as in *Hylodes*—or the larva is forced to change its habits, and then its ancestral features may be almost entirely obscured. This is the case with many larvae of insects.

In the actual history of the race, the transition from one set of habits to another and the accompanying changes of structure must have been gradual; but it often happens that in the course of time the transitional habits are not suited to the available environment and the corresponding stage is very rapidly passed through. During this period of rapid change the animal takes no food, and relies on the stores accumulated in the previous stage. See METAMORPHOSIS.

In embryonic stages yolk impedes the process of cell-division. In the normal cell this process is accompanied by a stiffening of the protoplasm; the two daughter-cells at the moment of division seem, as it were, to round themselves off by a kind of coagulation. This stiffening does not last, however, and after the division is completed the protoplasm again becomes semi-fluid and the two cells flatten themselves out against each other. When much yolk is present it acts exactly like water mixed with honey; it dilutes the protoplasm. Hence the amount of stiffening previous to cell-

division is much less, the division proceeds slowly and the cells produced are clumsy and large. During the period of relaxation, the daughter-cells often fuse with one another and the process of division is undone. When very much yolk is present, cell-division becomes quite impossible and only division of nuclei takes place.

In such eggs, where the protoplasm is concentrated at one pole, development proceeds rapidly in this area, whereas at the opposite

pole it is at first at a complete standstill. So the embryo gradually acquires the features of the adult, whilst bearing attached to it a huge sac filled with yolk. Such eggs are termed *meroblastic*, as opposed to *holoblastic* eggs, in which the whole egg is divided into cells. The yolk-sac is eventually surrounded by a layer of cells budded from the edges of the developing area; and as the organs of the embryo become formed the yolk is gradually digested, and conveyed by blood-vessels to the growing part of the body. The yolk-sac shrinks and its covering is eventually incorporated in the skin of the young animal. Amongst invertebrates meroblastic eggs are found amongst Cephalopoda (cuttle-fish), and it is a ludicrous sight to see a miniature squid attached to one pole of a large egg.

The organs of the embryo, as opposed to those of the larva, are functionless, and where they are not transformed into adult organs they are apt to be almost entirely suppressed; thus in the embryo of the earthworm no trace remains of the broad equatorial belt of cilia, which is so characteristic of the trochophore larvae of other worms and which forms their principal means of locomotion. So, too, in the embryonic development of most snakes no traces of the ancestral limbs are preserved.

The embryonic phase can be divided into three stages, which are respectively (a) segmentation of the egg, (b) formation of germ-layers, and (c) organogeny.

The segmentation of the egg means its division into a large number of cells or *blastomeres*. In the eggs of the most primitive creatures, in which there is little or no yolk, the blastomeres are almost equal in size to one another, and as they increase in number they separate from one another in the centre, so that they become arranged like a balloon round a cavity. This cavity is called the *blastocoele* or primary body-cavity, and the whole balloon is known as the *blastula*. In the case of the Echinodermata, Driesch has proved that the cells of the blastula not only look like each other, but are really like each other in their potencies, for if the blastula be cut into pieces any piece of sufficient size will round itself off so as to form a new blastula of reduced dimensions, which will develop into a perfectly normal larva.

When the distorting influence of yolk is absent or not much developed, the blastula stage can be detected in life-histories belonging to all the invertebrate phyla. Thus in Mollusca it is clear in the development of the limpet (*Patella*) and the pond-snail

(*Paludina*), amongst Arthropoda in the development of the fairy-shrimps (*Branchipus*), and of the water-fleas (Copepoda), amongst sponges it is seen in *Oscarella*, whilst it is almost universal amongst Coelenterata, Echinodermata, Nemertea (proboscis-worms) and Brachiopoda. In the sponge *Oscarella*, the coelenterate *Eudendrium* and in Echinodermata, the blastula is a larval stage, and therefore it may be legitimately considered as a recapitulation of a common ancestor of all the Metazoa. There exists even at the present time a hollow bell-like organism consisting of ciliated cells tied together by protoplasmic filaments. This creature is termed *Volvox*, and it is sometimes regarded as a compound Protozoan allied to the simple Flagellata.

The "formation of layers" implies the transformation of this balloon into a double-layered cup termed the *gastrula*, by the in-pushing of one of its sides. The inner layer, which is called *endoderm*, gives rise to the digestive layer lining the gut—the outer layer or *ectoderm* to the skin. From the inner layer pockets or cellular outgrowths are given off which give rise to body-cavity and muscles and these are termed the *mesoderm*. Ectoderm, endoderm and mesoderm are the three *germinal layers*. The gastrula can be recognized as a stage in the development of all Metazoa except sponges. It exists as a larva amongst the Echinodermata and, in modified form, amongst Coelenterata, in which it is known as the *planula*. The inner layer in the most primitive forms arises as a process of in-bending or *invagination*. It looks exactly as if it were pushed in by an invisible finger. The opening produced by this process is called the *blastopore*. The process of invagination can be analysed into three factors. There is (a) a process of growth and multiplication of cells at one point on the blastular wall which produces lateral pressure; (b) an alteration in character of the cells of the blastular wall. Although after the process of invagination has begun the cells at the animal pole look just the same as before, they have lost some of their original powers—for Driesch has proved that if the upper part of the blastular wall be cut off after this event, though it is able to round itself and form a new blastula, this blastula is incapable of further development; it has become ectoderm. The new cells formed in the zone of growth are from the beginning divided into two categories, one being ectoderm and the other endoderm; (c) a tendency to flow inwards towards the interior of the blastocoele. It is obvious that mere lateral pressure due to increased growth would be relieved by a bending outwards as well as by a bending inwards, and Driesch has shown that under abnormal circumstances this can actually happen with the gastrula of the sea-urchin. There must, therefore, be a special factor in normal development to ensure that invagination or bending inwards takes place. This we may call *inward cytaxis*.

The planula differs from the typical gastrula in that the in-growth of endoderm is a solid mass of cells, not a finger-shaped tube. This mass subsequently becomes hollowed out by the absorption of its central cells and forms the lining of the gut. Indeed, the Coelenterata might be regarded as retaining throughout their lives the gastrula type of structure. In some Coelenterata, such as *Aurelia* (the common jelly-fish), and *Urticina* (a common sea-anemone), the planula is replaced by a hollow gastrula and the blastopore becomes the mouth of the animal. If we have to decide whether the planula or the hollow gastrula gives the most faithful recollection of a distant ancestor, we must decide in favour of the gastrula. For in the history of the race there must have been continuity of function; at every stage in the process the animal must have been a working machine. Now, a solid mass of cells could not serve as an organ for digesting food, but a hollow tube is adapted to this end. Hence we conclude that the gastrula and not the planula gives us the truest picture of the ancestor.

The sponge *Oscarella*, as we have already seen, is hatched as a typical ciliated blastula. But it does not become converted into a gastrula. The hinder cells lose their cilia and become granular; in this stage the larva is termed an *amphiblastula* and the majority of sponges are hatched in this stage. The amphiblastula, like the planula, attaches itself to the bottom by its anterior end, but this end now flattens out and then becomes bent inwards and upwards whilst it is overgrown by a great extension of the granular cells

which form the outer dermal layer of the sponge. If we call the inbending of the ciliated cells invagination, then this invagination takes place at the opposite pole from that at which it occurs in the planula. From these ciliated cells the gastral or inner layer of the sponge and the so-called flagellate chambers are derived.

How shall we interpret this metamorphosis? If a blastula-like animal was the ancestor of all the Metazoa, there must have been a remote period in the world's history when the seas swarmed with this type and when nothing higher was in existence. If some of these blastulae, instead of seeking a living in midwater, like the rest of their brethren, descended to the bottom to feed and found it profitable to do so, then in this divergence of habit amongst members of the same strain we should have the explanation of the primary cleavage between the phyla Porifera and Coelenterata. Similar divergences of habit have taken place at every stage in the history of life.

The free-swimming blastulae in their search for food perhaps gradually substituted for a random rolling motion a screw-like motion in one direction, and so the posterior end became specialized for the capture and swallowing of food, whilst the front part became the organ of locomotion. So the gastrula grew out of the active blastula, and the cells at its anterior end being the first to encounter changes in the environment, became transformed into a sense-organ with stiff sense-hairs and alternately gave rise to the first nervous centre. Such a sense-organ has been demonstrated by Duerden in the planulae of certain corals. But the very same difference of habit which manifested itself at the blastula stage, supervened again. Some of the gastrulae sought the bottom and attached themselves there; these gave rise to the great army of plant-like polyps and sea-anemones which constitute the major portion of the Coelenterata. But there was a minority amongst the Coelenterata which never abandoned the original free-swimming life; these are represented in our present seas by the beautiful comb-bearers (Ctenophora) which propel themselves by eight radiating bands of cilia arranged in little transverse combs. These bands culminate in a beautiful sense-organ resting on a nervous cushion—situated, unlike the nervous centres of other Coelenterata, in front. Out of animals somewhat like these the evolution of most of the higher invertebrates has proceeded. The ctenophore is nothing but an active, sensitive, glorified gastrula, and in the life-history of the flat-worms (Platyhelminthes) the memory of this ancestor is preserved as *Müller's larva*. This larva, after a brief free-swimming life, sinks to the bottom and flattens out and becomes converted into a leaf-like flat-worm or turbellarian crawling on its cilia. Müller's larva is an oval organism with a sense-organ at one pole and along its sides eight ciliated lobes which correspond to the eight meridians of combs in the ctenophore.

In the life-history of the proboscis-worms (Nemertea) a larva termed the *Pilidium* occurs, which also seems to be a memory of a ctenophore-like larva. It is shaped like a helmet with a strongly developed sense-organ at its apex. Below there is a wide sac-like gut opening by a wide blastopore. The ciliated ribs have coalesced into a wavy circular band which, however, retains two side-lappets like the lobes of Müller's larva. The pilidium, however, is transformed into the Nemertine worm by an abrupt metamorphosis which, doubtless, represents an extreme compression of an originally long life-history, and which it has been impossible up to the present to interpret satisfactorily.

The trochophore larva which appears in the life-history of not only the shell-fish (Mollusca) but also the Polyzoa and the segmented worms (Annelida) is a further development of the ctenophore-like gastrula. The typical trochophore is an almost spherical larva, with an apical sense-organ at one pole essentially similar to the sense-organ of Müller's larva and the *Pilidium*. Round the equator is a belt of powerful cilia, by the aid of which the larva moves. This band is termed the prototroch: Wilson has shown in the case of *Patella* and Waltereck has proved in the case of the worm *Polygordius* that this ring consists at first of four separate lozenge-shaped patches, in which the cilia are arranged in transverse combs. The trochophore may thus represent a four-ribbed ctenophore-like ancestor. Below the prototroch

there is, as in the *Pilidium*, a sac-like gut opening by a wide blastopore, which changes into a narrow longitudinal slit, that becomes closed up so as to form a seam-like ciliated groove, except in front, where an opening persists which forms the mouth. In the primitive worm *Polygordius* there is an opening also at the hinder end of the seam which is the anus. In the case of other trochophores, the anus is usually formed as a new opening at the hinder end of the seam. In these processes we clearly have blurred memories of a history which converted the wide single opening into the gut possessed by the Coelenterata and the flat-worms (Platyhelminthes), into two openings, a mouth for taking in food and an anus for ejecting waste. Since the nemertine worm also has an anus, the pilidium larva represents only the early stage of the trochophore ancestor before the division of the blastopore and the later stage is obscured by the metamorphosis.

The second great advance shown by the trochophore is the formation of a true mesoderm. Two large cells, which in the early trochophore form part of the wall of the hinder part of the gut, are ejected into the primary body-cavity or blastocoele. Here each cell begins a process of active growth and multiplication. The daughter-cells are budded off in front, whilst the original mother-cell remains behind; in this way a band-like mass of cells, the so-called *mesodermal band* is produced, which develops a cavity termed the secondary body-cavity or *coelom*. From the wall of this cavity the germ-cells are developed, and it develops tube-like extensions which reach the exterior and form the so-called *coelomiducts*. Some of these serve as genital ducts (their primary function) and others secondarily acquire an excretory function. In front of the coelom a pair of string-like ingrowths of the skin or ectoderm cells become hollowed out to form vesicles or tubes. These are the primary excretory organs or *nephridia*.

The coelom turns up in other phyla where the trochophore larva is not formed, as for instance in the arrow-worms (Chaetognatha) and in the Brachiopoda. In these two phyla it is formed as a pair of hollow pouches of the gut, and on the same principles of interpretation which we employed in the case of the planula, we regard the out-pouching of the gut as the primitive method of forming the coelom, and the ejection of cells from the gut-wall as a secondary modification of this process.

If we now follow the trochophore in its gradual process of development into a worm and a mollusc respectively, we find that the change in the first case consists in the gradual lengthening of the body behind the prototroch. The intestine becomes drawn out into a long tube and the mesoderm into a long band. This

band becomes broken by cross fission into a series of blocks, in each of which a section of the coelom is formed by the absorption of the central cells. The skin becomes indented by a series of grooves corresponding to these blocks, and so the well known appearance of the segmented worm is produced. The prototrochal cells are then absorbed or cast off and the worm sinks to the bottom and begins its burrowing life, varied by brief seasons of spasmodic activity, during which it swims through the water by undulatory movements. These movements are carried out by alternate contractions of the longitudinal muscles on both sides,

and these muscles are developed out of the lateral walls of the segments of the mesodermal bands. When, however, the trochophore develops into a mollusc a different set of changes supervene. The body behind the prototroch becomes arched dorsally into a protuberance known as the *visceral hump*, inside which is contained the larval stomach. On the apex of the hump a saddle-shaped groove of thickened cells makes its appearance. This is the so-called *shell gland*, and by this gland a horny cap, the first rudiment of the shell, is secreted. On the ventral surface of the post-trochophoral body, a ciliated wedge-shaped projection grows out, along the line of the ciliated groove which marks the position of the sealed-up blastopore. This is the *foot*, by which the mollusc moves. In primitive Mollusca this movement is just a gliding by means of cilia over the bottom, but in more advanced and larger forms the ciliary movements are replaced by muscular wriggings. We can now catch a glimpse of the divergences of habits which led to the separation of the two great groups of Annelida and Mollusca. The trochophore stock, like the more primitive stock represented by Müller's larva, sought their food on the bottom. Under these circumstances two different modes of life were open to them. They might either seek their food in the most superficial layer of the bottom deposit, and in this case they became molluscs; or they might burrow into it, and in this case they became segmented worms (Annelida). But, as we have already pointed out, the Annelida really lead a double life; in all the more typical forms burrowing alternates with rapid swimming excursions through the open water. The accentuation of this later habit, and the gradual forgetting of the tendency to burrow led to the evolution of the great phylum Arthropoda, or jointed-leg animals, which contains about three-quarters of the known species of living animals.

The Arthropoda differ from the Annelida in the much greater thickness of the cuticle. The coelom has disappeared, leaving only occasional pocket-like remnants, so that the large body-cavity of the arthropod is really a blastocoele. In the early embryonic development of all the Arthropoda there are developed two well-marked mesodermic bands, just like those of Annelida, and in these transverse segmentation and coelomic pockets appear; in a word it might be said that the embryonic arthropod is an annelid. The three great groups of living Arthropoda, the Crustacea, the Arachnida and the Insecta, differ amongst themselves very much as to the extent to which the larval phase is developed. The Arachnida, except in their most primitive forms, leave the egg-shell with practically all the organs of the adult developed, but amongst the Crustacea the larval phase is strongly developed. It is a memory of the gradual transformation of an annelid into an arthropod and shows that this transformation began in front and gradually progressed backwards as the higher types were evolved.

The most primitive larval phase found in Crustacea is the nauplius, which has already been mentioned. This phase occurs as a larva in the Phyllopoda (leaf-foot Crustacea), the Copepoda, the Cirripedia (barnacles), the Ostracoda and amongst certain primitive members of the Malacostraca, shrimps, lobsters, crabs, etc. As an embryonic stage it can be detected in the life-history of the highest Crustacea. The nauplius is an oval or cylindrical larva with a single simple eye in front and three pairs of jointed legs, one pair slightly in front of the mouth and the two pairs behind it. The mouth is a transverse slit on the under side overhung by a large lip or labrum. The first pair of limbs consists of a straight rod on each side carrying sensory hairs and is termed the *antennule*: the second and third pair are forked, each limb consisting of a basal piece from which inner and outer branches spring, each having two or three joints. The

basal piece on each limb carries an inwardly directed hook which the larva uses for seizing its food. These hooks are termed masticatory hooks. The second pair of limbs eventually becomes the *antennae* of the adult, whilst the last pair become changed into the *mandibles*. In most nauplii the body behind the mouth is totally unsegmented but, as already noted, in the nauplii of the primitive Phyllopoda this region is long and cylindrical and marked out into a multitude of very fine ring-like segments. We may interpret this larva as a reminiscence of an ancestral worm, in which the first two or three segments had developed appendages suitable for grasping food, and in which the cuticle of this region was greatly strengthened, but in which the hinder part of the body retained largely its soft, worm-like character. It must be remembered that the marine worms have soft wing-like outgrowths from their segments known as *parapodia*, and it is these that are converted into the limbs of arthropods when the cuticle becomes thicker.

Since an arthropod is confined within a rigid cuticle, growth is only possible when this cuticle is thrown off. So the life-history presents the appearance of a series of stages of fixed appearance, known as *instars*, separated by shorter stages known as *moult*s, during which changes in appearance take place. Of course these changes are not really as sudden as they appear, for they have been gradually going on in the soft tissues underneath the cuticle, but they only become manifest when the cuticle is shed.

Want of space forbids us to describe in detail the various moults by which the nauplius larva transforms itself into a phyllopod, a copepod, a cirripede and an ostracod respectively. We propose to give only a brief account of the development of the Malacostraca.

In only the most primitive shrimps such as *Penaeus* is the young organism hatched as a nauplius; in the vast majority of cases, this stage is passed over within the egg-shell and the animal is born as a larva of quite a different kind, termed a *zoaea*. In the lobster even the *zoaea* stage is passed through before hatching; the young lobster begins its career as a larva of a more advanced type known as the *mysis* larva, but in the case of all the shrimps and crabs, the *zoaea* is the typical larva.

The *zoaea* is divided into an anterior rounded portion, the *cephalo-thorax*, and a hinder segmented portion ending in a broad tail fin, the *abdomen*. The cephalo-thorax ends in front in a spike or rostrum; at the sides of this are two large eye-stalks bearing compound eyes, whilst at the base of the rostrum, the single eye of the nauplius can still be detected. The cephalo-thorax is covered by an undivided shield termed the *carapace*, the sides of which form free flaps hanging down at the side of the body; between these flaps and the body is a groove in which are the first traces of the gills. Of the naupliar appendages, the antennule has shrunk very much in size, the antenna retaining its forked condition only in the primitive *zoaea* of *Penaeus*. In the *zoaea* of the common crab, for instance, as in most *zoaea*, the outer branch of this limb has assumed the adult form of a scale, the so-called *squame*. The mandible is reduced to its basal stump. Behind the mouth come two segments carrying the two additional pairs of jaws, the *maxillules* and the *maxillae*, which are common to all Crustacea. Behind the second of these is the groove which marks the limits of the head region, as distinct from the *thorax*. The segments of the thorax are exceedingly compressed—only the first two carry limbs; these are large forked appendages and are used in swimming. In the *zoaea* of the shrimp the first three pairs carry limbs. The abdominal segments are without appendages.

No adult crustacean exactly like the *zoaea* is found living. But if we watch how the larva uses its limbs, we see clearly that it represents a stage in functional evolution between the primitive arthropod represented by the nauplius and one of the higher Crustacea. In the primitive arthropod, swimming and getting food were functions carried out by the same limbs, but when the arthropod became a crustacean, three of the pairs of limbs, mandibles, maxillules and maxilla, were changed into jaws and the swimming function was relegated to the two or three pairs of limbs behind them which in later life became the foot jaws

FIG. 4.—AMPHIBLASTULA LARVA OF THE SPONGE, GRANTIA LABYRINTHICA

1. Flagellated cells. 2. Granular cells

or maxillipedes. The fact that in the crab zoea the hinder segments of the thorax and the segments of the abdomen have no limbs may be explained, in the same way as their absence was explained in the nauplius, by the assumption that in the ancestor they were thin and undifferentiated and of little functional importance. In the primitive zoea of *Penaeus* the second antenna remains, as in the nauplius, large and forked and still aids in swimming as it does in many of the lower Crustacea, and only one pair of maxillipedes is developed; this represents an older ancestral stage than the typical zoea. Weldon has given a vivid picture of the movements of a crab zoea; the little creature swims on its back, using the rostrum and a spine which sticks up from its back as a keel; it rows itself by its maxillipedes and uses the abdomen as a rudder. This last observation of Weldon throws a flood of light on the causes which led to the evolution of the abdomen. Strictly speaking, this term is only applicable in the higher Crustacea, in which the primitive uniform series of limbs behind the mouth is interrupted after the eighth limb, and the thoracic limbs or *peraopods* are succeeded by the much smaller abdominal limbs or *swimmerets*. The primary reason for the differentiation of the abdomen and the dwindling of its limbs seems to have been its use as a rudder.

The zoea of the shrimp gradually changes into the adult form by a series of moults. In these moults, some of the legs belonging to the hinder segments of the thorax make their appearance, and begin to take part in the swimming function. In extreme cases as many as six pairs of legs, all similar to one another, may eventually be engaged in this function. The larva now bears a striking resemblance to one of the Schizopod shrimps such as *Mysis*, and for this reason it is known as the *mysis-larva*. The lobster is hatched from the egg in this stage. The mysis-larva evidently represents an ancestor in which the swimming function has been adopted by more legs than was the case with the zoea ancestor. In the common shrimp the last four pairs of the thoracic limbs, however, do not develop into swimming organs, but remain as rudimentary buds till the final moult gives them their adult form. The mysis-larva is transformed into the adult shrimp by the appearance of the abdominal limbs and the disappearance of the outer swimming branches of the thoracic limbs. In the adult shrimp the thoracic limbs are used only for grasping and walking; swimming is performed exclusively by the abdomen, so that the swimming function which in the nauplius ancestor was performed by the most anterior appendages has been gradually passed back until it has reached the hinder end of the body.

In the life-history of the crab, the mysis stage is missed out, and the zoea moults four times, whilst still retaining the same general structure and appearance. But at each moult the hinder thoracic appendages become more prominent, although they are never forked and never become functional. The abdominal appendages, too, make their appearance as small buds. Then a final moult takes place at which the zoea completely changes its shape and becomes a larva of an entirely different type known as the *megalopa*. This larva strongly resembles a small lobster. It has all the last five pairs of appendages of the thorax as unforked limbs, and the abdominal appendages are fully developed and forked and adapted to swimming. At the next moult the megalopa changes at once into a small crab, but all the swimmerets disappear. Now the adult crab possesses four pairs of swimmerets in the female and in the male two pairs of modified swimmerets. The swimmerets in the female are quite normal in structure, but they are not used for swimming, but merely for holding the egg; the swimmerets in the male are modified into styles and are used for transferring the male cells into the female opening. These appendages are only developed as the little crab grows larger and approaches sexual maturity. Now, in the history of the race there is no doubt whatever that the swimmerets of the lobster ancestor became the swimmerets of the crab, and the disappearance and subsequent reappearance of these limbs in the life-history is one of the most curious phenomena of development and throws a great light on the nature of heredity. *We see quite clearly that what is inherited is not a structure as such, but a potency or memory which can embody itself in a structure when the func-*

tional necessity for it arises.

The development of insects shows the paradox that the most modified insects have a long larval life and that their larvae are worm-like in appearance, whilst the development of the lowest and most primitive insects is almost entirely embryonic, and they are hatched resembling their parents in most points except size. Many authorities hold, therefore, that the larvae of insects

are secondary modifications of the life-history and have no ancestral meaning whatever; but this explanation is in our view unnecessary. The best known larval form amongst insects is the familiar caterpillar. This creature has a pair of very short antennae in front. At the sides of the mouth are a strong pair of biting blades, the mandibles, followed by two other pairs of jaws; then follow the three segments of the thorax, each carrying, as in all insects, a pair of jointed legs and then the abdomen consisting of ten segments, of which segments II., IV., VI. and IX. carry a pair of soft, unjointed legs. Now, if we examine

BY COURTESY OF THE "QUARTERLY JOURNAL OF MICROSCOPICAL SCIENCE"

FIG. 5.—THE PILIDIUM LARVA OF THE NEMERTINE WORM, *CEREBRATULUS LACTEUS*

1. Apical sense organ; 2. Mesenchyme cells; 3. Mouth; 4. Stomach

the lowest and least specialized insects such as the little wingless *Machilis*, which scavenges amongst sea-weed left dry by the receding tide, we find that they also have short antennae, biting mandibles and an abdomen every segment of which carries a pair of unjointed legs; so that we see that the larva of a butterfly may be taken to represent an ancestor which had attained the level of the adult stage of *Machilis*. This conclusion is strengthened by two other sets of facts, viz.: (1) A closely similar caterpillar larva occurs as a phase in the life-history of the wood-wasps, which are primitive Hymenoptera utterly different in structure from the butterflies; (2) if we examine the embryos of insects like the cockroaches, which are hatched as so-called "nymphs" resembling the adult in most features but devoid of wings, we find in these embryos an almost complete series of unjointed abdominal legs. The caterpillar therefore need not be a secondary adaptation, because it occurs as a phase in the life-history of widely different orders, and it is found as an embryonic phase in life-histories where as a larval phase it is absent.

The most primitive land arthropod is the worm-like *Peripatus*; in the best-known species of *Peripatus* the development is entirely embryonic and takes place within the oviduct of the mother. In the course of this development a gastrula stage is clearly seen, which has a long slit-like blastopore that closes up in the middle and leaves the two ends open as mouth and anus. In the insect this blastopore is represented by a long groove on the under surface of the yolky egg, from the bottom of which cells are budded into the yolk, and at the two ends of which mouth and anus are formed.

The great difficulty is to explain why the caterpillar stage should be embryonic in such primitive insects as cockroaches, grasshoppers, crickets, etc., and in all the bugs, and larval in the highest insects such as the Lepidoptera (butterflies and moths) and the Hymenoptera. But the caterpillar does not develop continuously into the adult insect or imago. A resting stage, the chrysalis or pupa, intervenes. In this stage the larva is protected in a case either secreted by itself or composed of materials collected by it and stuck together by its secretion. It undergoes profound changes, and becomes changed from a worm-like form to that of an insect with rudimentary wings—in fact it becomes quite similar to the young of a cockroach or a grasshopper when this is just hatched. The wings develop in the primitive forms as external protuberances, in the more advanced forms from the bottom of deep pits. We see, in a word, that the chrysalis of the higher insects corresponds to the nymph of the lower insects. It is exactly as if the insect, having begun as a larva, had gone back

into an embryonic stage. Only a tentative hypothesis as to the cause of this anomaly can be suggested. We know, however, that insects of the cockroach and grasshopper type flourished exceedingly during the Carboniferous period and attained a gigantic size. Such large insects were never again produced. In the period which succeeded to the Carboniferous two catastrophes overtook the world. In the north there was widespread aridity and the pro-

FIG. 6.—THE NAUPLIUS LARVA OF CHIROCEPHALUS (SP.)

duction of extensive deserts, whilst in the south there was an equally widespread ice-epoch. One or both of these climatic changes, it may be suggested, forced the insects which survived them to modify their larval development profoundly. In the higher insects the middle period of development was converted into the chrysalis stage, whilst in the lower insects the earlier part of development, the caterpillar stage, became embryonic. The caterpillar, like the lowest insects, is a scavenger. It was retained as a larval form amongst the higher insects because the parent has had the intelligence to find a suitable environment for the larva and to lay its egg there.

The great group of the Echinodermata (spiny-skinned radiates) have typically life-histories with a very long larval phase and their larval forms are very different from any which we have as yet described. Living Echinodermata consist of four classes of free-living forms, the true star-fish (Asteroidea), the brittle-stars (Ophiuroidea), the sea-urchins (Echinoidea) and the sea-cucumbers (Holothuroidea). Each of these classes has its characteristic larva, but all these larvae are obviously modifications of one type. If we take the common sea-urchin (*Echinus miliaris*) as an example of the Echinodermata, we find that the eggs are small and alecithal, i.e., almost devoid of yolk. They segment rapidly into blastomeres of almost equal size and a typical blastula is formed, the cells of which are provided with flagella. By means of these it rotates within the vitelline membrane, which it very soon bursts; it then escapes and swims freely about as a larva. Within 12 hours cells are budded from one side of the blastular wall into the blastocoele; these cells, which are termed *mesenchyme*, are a sort of primitive connective tissue. They become massed in two places, right and left, and within these groups little tridents of calcareous matter are secreted which develop later into the larval skeleton. Before this is accomplished, however, one side of the blastula becomes flattened and in the centre of this surface an invagination gives rise to a finger-shaped gut or archenteron and the blastula becomes a gastrula. Within 30 hours, from the apex of this a little bilobed vesicle is cut off which promptly divides into right and left vesicles. These vesicles—outgrowths of the gut—are the rudiments of the coelom. After this event the gastrula becomes converted into what is known as the prism larva. Another side of the larva becomes flattened so that the original sphere becomes a wedge and the tip of the gut bends towards this second surface. In the centre of it there appears a shallow funnel which is the rudiment of the mouth and oral funnel or *stomodaeum*. This funnel meets and opens into the blind end of the gut and so a complete alimentary canal is established. The gut has now become divided by constrictions into gullet, stomach and intestine and the blastopore forms the anus. The cilia are now restricted to a ring around the edge of

the surface into which the mouth opens—and at the lower edges of the surface two blunt lobes or arms grow out. With the appearance of these lobes or arms the prism larva becomes a *pluteus* or “easel-like” larva, as it was first termed by its discoverer, Johannes Müller. The arms are supported by long spine-like outgrowths of the calcareous tridents. They occur along the course of the ciliated band and the first pair are known as the *post-oral arms*. But other branches of the tridents extend forwards along the sides of the gullet and mouth and here impinge on the ciliated band and give rise to a second pair of arms, known as the *antero-lateral* pair. Johannes Müller not having observed his larva in the living active state, placed it wrong way up, with the pointed posterior end above, and compared the four long ciliated arms to the legs of the painter’s easel. In order to distinguish this larva from the somewhat similar larva of the brittle-star it is now termed the *echinopluteus*.

As the echinopluteus grows, it develops four other ciliated arms, two overhanging the mouth termed the *pre-oral*—the calcareous rods supporting these grow from a median calcareous centre in the dorsal region above the gullet—and two at the sides behind the antero-lateral called the *postero-dorsal*—each of these is supported by a rod growing from a new centre on the side of the larva. The echinopluteus retains the same general appearance as it grows bigger and older, until at the age of about four weeks it suddenly descends to the bottom and changes into a young sea-urchin. Four crescent-shaped outgrowths from the ciliated band, two placed dorsally and two ventrally, are developed; these in later larval life become very large and on them the main part of the swimming function devolves; but these crescents, termed “epaulettes,” are peculiar to the genus *Echinus* itself and some allied genera. Want of space compels us to describe in briefest outline the change of the echinopluteus into the sea-urchin. The coelomic sacs formed in the prism larva become divided into anterior and posterior halves on each side. From the anterior section on the left side a small rounded vesicle termed the *hydrocoele* is budded off. Round this bud the whole organization of the future urchin is built up. The hydrocoele becomes bent into a short thick hoop, the ends of which join so that a ring is formed. This becomes the ring canal of the water vascular system. From the ectoderm opposite the hydrocoele a deep pouch is developed which becomes a closed sac. The roof of this sac is called the *amnion*. Its floor grows out to form the first spines and tube-feet of the future sea-urchin; into the tube-feet, of course, branches of the hydrocoele project. Through the centre of the floor a new intucking marks the position of the adult mouth, which has no known relation to the larval mouth. The whole complex of spines and tube-feet is known as the *Echinus-rudiment*. From the anterior coelomic sac on the *right* side a small vesicle is budded off the corners of which lie above the gullet almost in the mid-dorsal line. This sac is called the “*pericardium*.” Its floor is bunched up to form a tube and the space—part of the blastocoele—included between the upper wall of the gullet and this floor is called the heart. The tube-like ingrowth pulsates rhythmically and causes the blastocoele fluid to circulate.

As the larva grows older the “*Echinus-rudiment*” increases in size till it occupies the whole side of the larva. Finally, the “*amnion*” becomes absorbed and the first tube-feet project freely. Then these feet take hold of the substratum and in a marvellously short time—about half an hour—the larval arms are all absorbed, the ciliated band and ciliated epaulettes vanish. The larval buccal funnel loses its connection with the gullet, shallows out and disappears, and the easel-like larva is reduced to a minute round flattened disc, which then takes up the ordinary creeping life of the sea-urchin.

The larva of the brittle-stars (Ophiuroidea) is also called a *Pluteus*. In fact it is the original *Pluteus* which was described by Johannes Müller. It differs, however, in many important respects from the larva of the sea-urchin and for this reason it is now termed the ophiopluteus. The eggs of brittle-stars agree closely with those of sea-urchins in their segmentation, blastula and gastrula stages, and in the way in which mouth arms and coelom are formed. In the early pluteus stage, however, the first arms

to be formed are not the post-oral, but a pair growing out from the sides of the larva. These arms (occasionally present in the echinopluteus) are directed forwards and are the longest arms of the larva. They are followed by antero-lateral, postero-dorsal and post-oral arms, but no pre-oral arms are formed, so that here again we find an eight-armed larva; but the arms are not quite the same as those of the echinopluteus. The arms are stiffened by calcareous rods, but all the rods on the same side of the larva are outgrowths of the same calcareous star. The coelom is formed in the same way as in the echinopluteus; it divides and gives rise to the hydrocoele bud in the same way; but the history of this bud is rather different. It becomes converted into a ring-canal, and this ring-canal gives off five lobes, *but these lobes project, not into an amniotic space, but into the buccal funnel of the larva.* As the ophiopluteus grows older, the ciliated arms become absorbed; but the postero-lateral ones persist and even grow longer. The buccal funnel of the larva shallows out and disappears, thus exposing the first formed tube-feet, which take hold of the substratum and there metamorphosis is completed and the creeping life of the adult is begun. Then the postero-lateral arms finally disappear. *It is to be noted that here the adult mouth is the opening between the buccal funnel of the larva and the gullet and that no new opening is formed.*

The larva of the ordinary starfish is called the *bipinnaria* and seems at first glance very different from both the echinopluteus and the ophiopluteus. Closer examination reveals its essential similarity. The egg segments in the same way and the blastula and gastrula stages are the same; the larval mouth, the coelom and arms are formed in the same way. But the next stage is sausage-shaped. This shape is due to the existence of a long forehead or pre-oral lobe in front of the mouth. Into this the anterior division of the coelom extends on both sides and two sacs fuse into a median sac in front of the mouth. When the ciliated band is formed out of the general ciliated covering of the gastrula, it runs along the sides of the larva to the front end; arrived here it bends backwards along the underside of the pre-oral lobe. This loop of the band is soon constricted off from the rest and forms a special pre-oral ciliated band. Both bands, the pre-oral and the main one, develop outgrowths, but these are not supported by calcareous rods; they resemble the wings (pinnae) of insects, whence the name *bipinnaria*. The main band of cilia develops a median anterior "pinna." The division of the coelom into anterior and posterior portions takes place as in other echinoderm larvae; and the hydrocoele bud develops as in the sea-urchin, but there is no amnion formed and the primitive tube-feet from their first appearance project freely to the outside. The adult mouth is formed as a new perforation in the centre of the hydrocoele ring. What distinguishes, however, the *bipinnaria* from the other larvae of free echinoderms is the mode of its metamorphosis into the adult. After swimming about for two months, during which time the hydrocoele and its appendages grow larger in relation to the rest of the body of the larva, the *bipinnaria* develops at its anterior end between the pre-oral and main ciliated bands a group of three short arms ending in adhesive knobs; by means of these the larva anchors itself to the substratum. It has now become a *brachiolaria*. An oval suctorial disc, consisting of sticky cells, is developed at the apex of the forehead between the bases of these arms; by the contraction of the arms the disc is brought into contact with the substratum (often a bit of seaweed) and so a permanent fixation of the larva is effected and the pre-oral lobe is converted into a stalk. After becoming fixed, the ciliated bands and their pinnae disappear, and the stalk shortens till it becomes a small knob. The buccal funnel of the larva shallows out and disappears, the shortened stalk is attached near the adult mouth to the under surface of the future starfish. Finally, as the hydrocoele and its tube-feet become more and more developed, the starfish wrenches its vestigial stalk loose from its attachment and walks away.

The *auricularia* larva of the sea-cucumbers resembles the *bipinnaria* in outer appearance. There is a pre-oral lobe, though not as well developed as that of the *bipinnaria*; and the ciliated band is prolonged into a pre-oral loop on the underside of this lobe

but this is never quite cut off from the main band. The band grows out into lobes or pinnae, which, like those of *bipinnaria*, are not supported by calcareous rods. There is a blunt anterior median one, and the postero-lateral pinnae are long and curved and have been compared to little ears (*auriculæ*), whence the name of the larva. The development of the coelomic vesicle is different in the *auricularia* from what it is in other echinoderm larvae; it remains unpaired and divides into anterior and posterior halves; the posterior portion subsequently divides into right and left halves. The anterior portion, which represents the left anterior vesicle of other larvae, gives rise to the hydrocoele; this grows round the larval gullet, no separate adult mouth being formed. The *auricularia* swims about, gradually growing bigger for a fortnight, and then suddenly changes into another larval form known as the *pupa*. This is smaller than the *auricularia* and its tissues are much more dense and opaque. The first-formed tube-feet grow out into the buccal funnel (larval stomodaeum). When the change into the pupa occurs this stomodaeum deepens and its opening becomes narrowed and practically closed; it is then known as the *atrium*. The atrium shifts from its original ventral position to the left side of the larva and then by the shrinkage of the pre-oral lobe, the opening of the atrium becomes terminal. At the same time the ciliated band of the larva becomes broken into short pieces which re-unite to form circular bands of cilia surrounding the pupa as the hoops surround a barrel.

The first-formed tube-feet project into the enlarged buccal funnel or atrium just as they do in Ophiuroidea; but these tube-feet are not terminal appendages of the radial canals, as they are in the other three classes, but basal ones—the so-called buccal tube-feet, which, in the adult sea-cucumber, are arranged around the mouth and are used to collect food. The radial canals extend along the body of the pupa outside the atrium. After swimming for a few days the pupa loses its ciliated bands and drops to the bottom; it develops a skeleton of calcareous plates almost touching one another and recalling the shell of a sea-urchin. The atrium opens and the tentacles protrude and begin to collect food and tube-feet develop on the radial canals, first on those that lie on the under side of the sausage-shaped animal and then on those that lie on the upper side.

From the descriptions just given it seems clear that the *bipinnaria*, *ophiopluteus*, *echinopluteus* and *auricularia* are modifications of one original type of larva. In our view, this larva is a recapitulation of an original free-swimming ancestor of all the echinoderms, which, like most free-swimming animals, was bilaterally symmetrical. Like the trochophore, the echinoderm larva gives evidence of having passed through blastula and gastrula stages in the history of the race, but there the resemblance ends.

FIG. 7.—THE MYSIS LARVA OF THE AMERICAN LOBSTER, HOMARUS AMERICANUS

1. Antennule; 2. Antenna; 3. The seven pairs of exopodites born by the thoracic limbs

The protoplasm of the cells composing the trochophore blastula is already specialized, so that when these cells are separated from their fellows, they pursue, so long as they live, the same development as they would have done in the intact organism. The cells of the echinoderm blastula, on the other hand, are unspecialized; any sufficiently large portion of the blastula wall will round itself off and form a blastula of reduced size, which will pursue a normal development and give rise to a small normal larva. The echinoderm larva is, therefore, in a much more primitive condition than the trochophore larva from which Annelida and Mollusca have very possibly been derived. We saw that the ciliated band of the trochophore was built up of four discrete groups of ciliated cells which very probably represent the "ribs" of a ctenophore ancestor. The ciliated band of the echinoderm larva shows no such indications; it is not transverse but obliquely longitudinal, crossing the dorsal surface on the pre-oral lobe or forehead and the ventral surface in front of the mouth. The

coelom in the trochophore is a derivative of the growth of two large cells—originally part of the gut wall. This method of formation represents an original gut-pouch, modified in connection with the extreme specialization of the cells of the trochophore; in the echinoderm larva the origin of the coelom from a gut-pouch is obvious. Another difference concerns the fate of the blastopore. This in the trochophore closes up in a longitudinal seam, one end of which remains open as the mouth, while in some very primitive forms the other end remains open as the anus. In the echinoderms the blastopore is always a round hole which persists as the larval anus, and the mouth is a new opening formed apparently completely independently of the blastopore. To sum up, the trochophore and the echinoderm larva both represent simple free-swimming ancestral forms which were, however, markedly different from one another; to trace these back to a common root it is necessary to go back almost to the beginnings of the Metazoa.

The most remarkable feature in the life-history of the echinoderms is their change from the bilateral symmetry of the larva to the radial symmetry of the adult.

It is obvious that no light is thrown on its meaning by the sudden metamorphoses of sea-urchins, brittle-stars and sea-cucumbers. In the life-history of the common starfish (Asteroidea), however, a fixed stage intervenes between the free-swimming phase and the crawling adult. Some members of other phyla desert the open water to seek food at the bottom—and in many cases—owing probably to the existence of powerful currents, they develop the habit of holding on to one place and seizing the food as it drifts past them. All such animals tend to develop tentacles on all sides, for instance, the Polyzoa (*q.v.*). If in the fixed echinoderm ancestor the hydrocoele had already developed its tentacles; then these must have been developed on both sides, and in asteroid, ophiuroid and echinoid larvae a second hydrocoele bearing tentacles is occasionally developed on the right side as well as on the left. But some constitutional peculiarity of the stock favoured the left side at the expense of the right, and so this hydrocoele developed into a ring suppressing the corresponding organ of the right side altogether. The formation of this ring and the functional importance of the organs developed from it is the foundation of the radial symmetry; all the other organs of the body are adapted to it. As the ancestral starfish spread into more tranquil waters, they wrenched themselves loose from their stalks and gave rise to the free living Echinodermata. The Ophiuroidea are only more specialized starfish, and the sea-urchins, when just metamorphosed, are little flat disc-like starfish, in which nothing of the globular form of the adult can be seen. They developed, we may suppose, out of starfish which took to climbing in vertical crevices—situations which mountaineers call chimneys—and in these circumstances the tips of the arms were bent upwards to get a better grip of the cliffs above them and so the globular form was attained. The sea-cucumbers are perhaps the result of a further development of this habit, for from climbing vertical walls to wriggling amongst stones is an easy passage; but the young post-larval sea-cucumber still show traces of the shell of the sea-urchin ancestor from which it was derived.

There still exist at the present day a few stalked echinoderms, represented by the class Crinoidea—the last survivors of an immense multitude of Palaeozoic forms, so numerous at one time that vast masses of limestone are formed of their accumulated remains. The stalk springs from the centre of the back, whilst mouth and anus are both on the opposite surface. The eggs of the only crinoid whose development has been worked out are large and full of yolk, and the earlier stages of development are embryonic, and during the short larval phase the young animal takes no food. Nevertheless, this larva shows in broad outline some resemblance to the bipinnaria, although the cilia are arranged in transverse bands as in the pupa of sea-cucumber. It has a long pre-oral lobe containing a single anterior body-cavity; and at the apex of this lobe there is a sucking disc by which it soon fixes itself and the pre-oral lobe is then changed into a stalk. There is a larval buccal funnel or stomodaeum, which, however, never opens into the gut, since the larva takes no food, and into this funnel the first tentacles project just as they do in Ophiuroidea and

Holothuroidea. But the changes which supervene after the larva is fixed are quite different in the Crinoidea from what they are in Asteroidea. The buccal funnel of the larva, instead of being pressed closer to the substratum, as it is in the starfish, is rotated backwards till it reaches the posterior pole of the larva, which is, of course, directed upwards towards the open water. Then it opens and the ciliated tentacles spread out and collect the microscopic plants and animals that swim freely through it. We now see that the wide distinction between the fixed and free echinoderms rests ultimately on a different choice of food. When the ancestral echinoderm began to hold on to the ground with its pre-oral lobe and to grope about in the water with its tentacles for food, two courses were open to it—it might either bend downwards to grasp what was drifting beneath it, or reach upwards to attain what was floating above it—the first course led to the development of the free echinoderms, the second to the crinoids.

If we search through the animal kingdom for larvae resembling those of echinoderms, we find such a larva only in the phylum Enteropneusta. This is the tornaria larva of the worm-like *Balanoglossus* which is described in the article *BALANOGLOSSUS*. But the resemblance is so close that tornaria was actually regarded as an echinoderm larva until its life-history and metamorphosis were known. It has a longitudinal ciliated band with a pre-oral loop which resembles that of the auricularia. It has a long pre-oral lobe containing a single anterior coelom like the bipinnaria. Besides this coelomic sac, a pair of anterior sacs at the sides of the gullet represents the hydrocoele, and its missing fellow on the right side and a pair of posterior sacs represent the posterior sacs of the echinoderm larva. Most striking of all, it has above the gullet a small pericardial sac, the floor of which vibrates and acts as a heart, exactly as it does in the larvae of Asteroidea, Ophiuroidea and Echinoidea. The tornaria has some additional features. There is a posterior transverse ring of cilia behind the longitudinal ciliated band and an apical nervous plate with two eyes at the apex of the pre-oral lobe. Such a plate is not found in the bipinnaria but is found in the echinopluteus. The fate of the tornaria larva is different from that of the echinoderm larva because the adult habits are different, but there can be no serious doubt that it represents the same ancestral stock. An ally of *Balanoglossus*, *Cephalodiscus*, actually uses its pre-oral lobe for temporary fixation and has the middle section of the coelom on each side developed into long ciliated tentacles. As pointed out in the article *BALANOGLOSSUS*, this animal in its gill-sacs, and rudimentary nerve-tube and notochord, shows unmistakable affinities to the vertebrates, so that here the embryology of the Invertebrata merges into that of the Vertebrata.

In this article we have striven to give some idea of what has already been gleaned as to the past history of life by the study of invertebrate embryology. But what has been discovered is only a small fragment of what is still unknown and could be known if more life-histories were studied and compared.

technical skill in judicial proceedings, subject to legal rules and forms in which there must be elucidation of questions relating to crime. This covers the questions: who the victim was; the exact place at which the offence occurred; how the crime was committed, with what weapon it was committed, or what were the means employed in its commission; what was the time of attack, what was the motive or object of attack, and the identity of the offender or offenders. Criminal investigation is employed also in the search for and interrogation of material witnesses who are able and willing to give competent and relevant testimony against the suspect or offender, and in the reconstruction of all facts connected with the crime in order that, at the trial of a defendant, a true picture of what occurred may be presented in such manner as to leave no doubt in the minds of the jurors or judge regarding the guilt or innocence of the accused.

History.—Although the beginning of criminal investigation is unknown there is reason to believe that in a very rudimentary form it came into existence with the origin of legal trials. It is clearly laid down in the Code of Hammurabi (c. 2250 B.C.) that suspicion does not give ground for condemnation; receiving of testimony, and even elaborate examination of sites or circumstances by the court itself, were established rules of procedure. In Athens, by about 500 B.C., the examination of facts had become meticulous; a defendant, having lost his case, might bring suit against a witness for bearing false testimony and, if successful in his new suit, would go free of his earlier condemnation. In the Fuotinian legislation (6th century A.D.) evidence was so construed as to imply the co-operation of experts in certain cases. In the middle ages, whether in civil or in ecclesiastical courts, and generally in the commercial and customary tribunals, the weighing of evidence was as careful as it has ever been. The introduction, in that period, of courts of inquest whose object was avowedly to procure condemnations, such as those of heretics, and the survival of certain ancient uses of the ordeal have obscured the prevalence of careful taking of evidence in the middle ages.

In 1507 a penal code containing exact instructions as to evidence was issued by a bishop of Bamberg, and in 1532, the Caroline code of the German States contained provisions for the examination of criminals. In 1575, a French physician described the form in which judicial reports should be made in medico-legal cases, and at the close of the 16th century, outlines of the method of testifying in such cases were numerous, especially in Italy. Toward the end of the 18th century, legal medicine was recognized as a science. Orfila, who occupied the chair of chemistry and medical jurisprudence in the University of Paris, was employed as an expert in judicial proceedings; in 1814 he published a *Traité des Poisons*. In 1689 Johannes Bohn, of Leipzig, published a work on the examination of wounds, the distinction between ante-mortem and post-mortem wounds, the different effects of death by injury, strangulation and drowning. In another of his works, published in 1704, he gives rules for the conduct of physicians during court testimony. During the latter part of the 18th century German scientists published numerous books on the subject. Lectures in medical jurisprudence were given at the University of Edinburgh in 1792, and in 1806 the university gave the title of "Professor of Medical Jurisprudence" to A. Duncan, Jr. Percival, with his *Medical Ethics* (1803), made himself one of the first noteworthy English contributors to medical jurisprudence, and was followed by John Gordon Smith. In 1823, Paris and Fonblanque published the first English work which associated the medical and legal professions. In 1836, Dr. Alfred Swaine Taylor published his *Elements of Medical Jurisprudence*, an authoritative work. The first Spanish treatise on legal medicine (1796-97) was written by Juan Fernández de Valles. In 1844, Prof. Pedro Mata of Madrid published the first edition of a work on legal medicine and toxicology, which, in the development of its subsequent editions, has become the most important Spanish treatise on the subject. The fathers of the modern school of scientific investigation are Dr. Hans Gross, formerly a professor of criminology; Dr. R. A. Reiss, of the University of Lausanne, and Dr. Alfred Niceforo. Most procedure now follows

their principles.

The old trial-and-error method in criminal investigation is being rapidly displaced by scientific methods, including the use of very highly specialized instruments. Philip Valois initiated the modern police system of criminal investigation. In Paris, in 1327, he appointed *commissaires*, or royal officers, who were not part of the judicial system and who conducted preliminary examinations in the enforcement of police regulations. The *Maréchaussée*, a military police, was organized in 1356, becoming the *Gendarmerie* in 1720. The first modern police organization, however, was founded in London in 1829. Twenty-five years later the Paris civil police were reorganized on the London model. In 1830 all ungarrisoned Prussian cities were authorized to establish a police force.

Police investigators of crime were originally spies. In England they entered the service to obtain rewards offered for the capture of criminals and in France for political prestige and pecuniary rewards. Later, members of the uniformed force were detailed to plain clothes police duty. These officials cultivated the acquaintance of criminals and of persons able to supply information for the apprehension and prosecution of offenders. The results justified the experiment and the plain-clothes man of yesterday is the police detective or criminal investigator of to-day, whose chief stock in trade is common sense, with coolness, courage, patience, perseverance, an analytical mind and a large acquaintance with criminals.

Since the majority of crimes reported to police departments are offences where property is obtained by theft, fraud or violence, police departments, drawing from their large experience in such investigation, have developed fairly effective technique; criminal investigation methods successful in one community have been adopted by others until there is now a certain uniformity in procedure. Existing differences in technique are of minor importance and are traceable either to local conditions or to the emphasis placed by police executives on one or another phase of general procedure.

Large police departments divide the detective force into small groups, members of each group devoting their attention to a particular type of crime or criminal. Investigators detailed for duty with the pickpocket squad have little interest in, or knowledge of, the practices of burglars. Men employed in combating the activities of hold-up men frequently know little or nothing of the passer of worthless checks, but seek to acquaint themselves with the name and address, associates, habits and haunts of every bandit at large in their community. A member of the burglary squad may know who is implicated in a complaint made to the police department as soon as he reads the details of the crime.

MODERN METHODS

Classification of Criminals by their methods of operation is now a permanent and invaluable feature. Some departments use the Atcherley *modus operandi* system for this purpose. Major-General L. W. Atcherley, originator of this system of classifying criminals according to their *modus operandi*, utilizes the following classes:—

- (1) *Classword*—Kind of property attacked, whether dwelling house, lodging house, hotel, etc.
- (2) *Entry*—The actual point of entry, front window, back window, etc.
- (3) *Means*—Whether implements or tools used, such as a ladder, jimmy, etc.
- (4) *Object*—Kind of property taken.
- (5) *Time*—Not only time of day or night, but whether church time, market day, during meal hours, etc.
- (6) *Style*—Whether criminal describes himself as mechanic, canvasser, agent, etc., to obtain entrance.
- (7) *Tale*—Any disclosure as to his alleged business or errand which the criminal may make.
- (8) *Pals*—Whether crime was committed with confederates, etc.
- (9) *Transport*—Whether bicycle or other vehicle was used in connection with crime.
- (10) *Trademark*—Whether criminal committed any unusual act in connection with crime, such as poisoning a dog, changing his clothes, leaving a note for the owner, etc.

Many departments use their own system for keeping a record

of the criminal's specialty. Race, age, sex, colour, class and occupation of the victim are noted. Whether the attack occurred in a dwelling place, office, public or semi-public building, store, shop, vehicle, vessel, public place or on a thoroughfare, is an important item in classifying the criminal. How a burglar entered an enclosure, particularly the actual point of entry, as for example, first floor, kitchen door or second storey, rear window, or how the bandit attacked his victim, whether by beating, drugging, or otherwise, are additional means of connecting the criminal with the crime. Tools, instruments, devices, or weapons used, or means employed in committing the offence, the actual time of day, as well as the particular day, the kind of article stolen and all individual characteristics associated with the offence are factors which assist in narrowing the scope of investigation.

The object clue is always important. Second-hand dealers and pawnbrokers are required to furnish a description of all articles sold or pledged. Although the laws regulating pawnbrokers and second-hand dealers vary somewhat, in the main they require that every person who carries on the business of pawnbroker or who purchases gold bars, gold quartz or gold bullion, or mineral containing gold, shall, at the time of the transaction, enter in a register kept by him for that purpose, the date, duration, amount and rate of interest of every loan made by him; an accurate description of the property pledged; the estimated value of the property purchased; the name, residence and description of the pledgor or seller. A written copy of such entry shall be delivered to the pledgor or seller and a written account shall be kept of all sales made by the pawnbroker or seller. Police investigators assigned to pawnshops visit these and second-hand stores regularly to inspect the records and view all articles sold or pledged.

Record-keeping.—In the written report which the criminal investigator makes of stolen property, he separates the identifiable from the non-identifiable articles. His report eventually reaches a police clerk who writes a description of each identifiable article on a 5 × 3 in. card. These cards are then filed in cabinet drawers behind appropriate guides. Unnumbered articles are filed according to an elaborate decimal system, or behind alphabetically arranged guides containing the names of the articles. Numbered articles such as watches, cameras, automobiles, etc., are filed behind numerical guides. The last two or three figures in the number are arbitrarily used as primary guide divisions. Cards are arranged in strictly numerical order within these divisions. Thus, in a two-number system, a card containing a description of a watch numbered 1,100 would be filed behind the guide 00 and would follow the card in this division numbered 1,000. A record of all articles pledged or sold is also filed in these cabinets. Pledged or sold articles are distinguished from stolen property by different coloured cards. Hence, when two cards containing the same description or numbers, but on different coloured cards, are brought together in the files, it means that property, which has been stolen and reported to the police department has been located in a second-hand store or pawnshop. As previously stated, the pawnshop or second-hand store record contains a description and signature of the pledgor or vendor and this information frequently helps the police investigators in their search for the criminal.

Police investigators still believe in "fighting fire with fire" and retain a remnant of the old spy system. Criminals, prostitutes, gamblers and other underworld characters are employed as undercover agents and report regularly to one or more contact officials, whom the chief of the criminal investigation division designates. A safe-breaker lavishly spending money; a bandit or burglar suffering from gunshot wounds; an automobile thief possessing numerous licence plates; a pawnbroker or second-hand dealer buying "hot stuff" (stolen articles) and neglecting to enter the sale as required by law; robbery, burglary or theft being planned; criminals proposing to move from one community to another;—all these are types of instances reported to the contact official or officials by undercover agents. These may have important bearing upon a crime that has already been committed or may be committed in the future. Apart from the regularly employed undercover agents, individual investigators obtain information

from criminals and other persons that they have befriended and thus clear up a baffling mystery that would otherwise be unsolved.

An old, successful investigator once said, "I spend most of my time cultivating the friendship of people who can help me to clear up crimes that are assigned to me for investigation; they often pay enormous dividends on a very small investment."

PRINCIPLES OF INVESTIGATION

General Rules.—Hans Gross's rules for guiding investigators are quite generally observed by police detectives assigned to investigate crimes. Briefly, they are: Take the simplest view at the outset and disregard all strange and extraordinary suppositions; omit the romantic features of fiction writers, remove exaggerations and confine the investigation to bare facts; never follow one idea exclusively; since women play either an indirect or direct part in many crimes and also aid in the concealment and escape of criminals, it is well to look for the woman in the case; search for causes; observe and report on all facts; make comparisons; examine localities with minute care; make measurements of places and things, and take photographs; check statements of witnesses as to time and distance, also memory of events and persons in order to determine whether their statements rest on false suppositions; remember there is usually one great blunder which a criminal nearly always commits, especially in big crimes; interview persons who have been employed in the district and know the inhabitants; endeavour to find the victim, relative or interested person from whom the preliminary information regarding the crime can be obtained; never alter the position of, pick up, or even touch an object before it has been minutely described in the report; note all points where traces of the crime or important details are to be found, e.g., clothing, finger-prints, foot-prints, hair, marks caused by firearms or tools, impressions and stains of all kinds—in short, everything which may have been produced by the criminal and everything which may have been left behind by him. Absolutely everything must be carefully examined, for there is no place where important objects connected with the crime may not be found. Often the strongest proof is found in the smallest details. Foot-prints, traces of blood and forgotten or discarded objects must be protected until experts have had an opportunity to collect or preserve such evidence. The ultimate objective of the examination or interrogation is to give the investigator of the occurrence as much detail as if he had been present in person. The investigator must have a wide acquaintance with experts and their capabilities for they are indispensable assistants and their findings and conclusions enable the detective to obtain a broader perspective of the case.

The Expert.—Police photographers and finger-print experts are commonly employed by criminal investigators, and experts in special fields occasionally assist in clearing up crimes. Seemingly insoluble problems have been unravelled by workmen and artisans of every trade, occupation or profession.

Obviously, medico-psychologists are valuable aids of the police, and the types of cases in which they assist cover a very wide field: ante-mortem and post-mortem examinations of wounds; all fractures and contusions; blood examinations; determination of the cause of illness, death or abnormal behaviour; observation of mental conditions of victims and suspects; and the restoration of decomposed, discoloured, mutilated or mummified remains. In many cases they are able to give the exact race, stature, age and sex from a study of the teeth and skeletal remains. On one occasion, the mutilated and mummified remains of a murdered woman were soaked for three hours in a 1% solution of potassium-hydrate and then placed in a 2% solution for 18 hours. After the soaking process, the body was drained and dried, cuts in the cheek were sewed up, cavities in the head and face were stuffed with cotton and then filled with plaster of paris, the filled-in places were smoothed over with flesh coloured embalmer's wax, artificial eyes and hair were placed in position, a missing ear was worked up in wax, flesh tints were added, and eyebrows and lashes painted on. A photograph of the reconstructed body was then taken and easy identification was made possible. Very slight traces of blood may be readily distinguished with the aid

of the Dudley Roberts occult blood test. When a stain is definitely determined to be blood, the pathologist utilizes the well known precipitin test to discover whether it is human blood or not. A microscopic study of the size, shape and colour of the corpuscles often makes it possible to determine from which particular group of animals the blood has come.

The micro-analyst recognizes at a glance all the structures which may appear within the field of the compound microscope and interprets the findings with a reasonable degree of accuracy. Lower plants and animals, plant and animal tissues, vegetable, animal and inorganic fibres, starches, dextrans, sand, soil and minerals are readily identified and their connection with the case under investigation may be quickly established. Dust or stains found in or attached to clothing or weapons, also deposits found under finger-nails, have furnished the investigator with the only and occasionally the most important clue. A single hair from the head of a human being has pointed unerringly to the perpetrator of a felonious offence. The fact that it was human hair, also the age, sex, race, probable colour of eyes, and probable weight of the person to whom the hair belonged, were ascertained by the micro-analyst after examining the four structural parts of the one strand that was left behind by the criminal. The hair of every furbearing animal has its own characteristics and these characteristics are so well defined that the expert experiences little difficulty in determining the type of mammal from which the single strand of fur came (see **HAIR**).

The chemical analyst is employed in all cases where the investigator believes that poison has been given, whether through the mouth or otherwise. He may also supplement the work of the micro-analyst. These experts are able to prove the nature of the substance that was administered and to determine also the nature of organic or inorganic substances that play an important part in any criminal investigation. Particles of dust may prove distinctly injurious to some persons and sometimes perfectly healthy people are affected fatally by doses of common drugs or by simple kinds of food. When this occurs, the chemical analyst will discover the true cause of death. Such information has occasionally cleared accused persons.

Firearms.—Forensic ballistics is that branch of criminal investigation which deals with the identification of firearms, bullets, cartridge cases and explosive materials used in guns. Experts in this field study also the effect and trajectory of bullets fired from guns; they can determine whether a bullet was fired from, or a cartridge case ejected from, a particular firearm. After examining a bullet they are able to state the make, calibre, type, approximate date of manufacture and the approximate serial number of the gun from which it came. This information is obtained by studying the following points on the bullet:—number of rifling lands, pitch or twist of rifling, width of grooves and lands, depth of grooves, calibre and weight of bullet, and the individual characteristics which are to be found in the barrel of every firearm, such as rough spots, gouges, imperfections and emery marks. These peculiarities are impressed upon the bullet when fired from the gun.

Identification of cartridge cases discharged from an automatic weapon is made possible by examining the scratches on the side of the case which are produced by the several mechanical operations connected with automatic loading and unloading, the marks made by the extractor hook, the firing pin imprint on the primer, the breech face imprint on the primer and shell base, and the imprint of the ejector blade or shoulder. When the cartridge case has been exploded in a revolver, the firing pin and breech face impressions on the primer and shell base furnish means for identification. Chemical composition of alloys used in the manufacture of bullets is easily ascertainable from slight traces of the metal, especially if the composition is unusual, while micro- and chemical analysis of powder found upon a bullet, even after it has entered a foreign body, has revealed the manufacturer's formula.

To the handwriting expert are referred questioned documents of every description. He studies erasures, obliterations, additions to writing, false seals, water marks, imitations of stains or marks of any character whatever on the paper, age and chemical nature

of inks and papers, type of pen or pencil used.

Photography and the Deception Test.—Photography and photo-micrography play an important rôle in criminal investigation. Speaking of the value of the photograph to the criminal investigator, Reiss says:—“(1) It constitutes an indestructible document taken automatically which reproduces all the facts and acts as an artificial memory. (2) It is a help to all those called to discharge duties during the trial without knowing the place of the crime. (3) It is able to exercise a psychological effect, whether upon the jury or on the judge. (4) The little details photographically revealed upon the place of the crime, such as the foot impressions, the digital markings, or anything of that nature, aid in the conviction of a criminal or the finding of the one responsible for the crime.”

Briefly, the camera is employed as a recording agent whenever it is desired to obtain absolute, objective, permanent and easily controlled proofs.

Recently one other tool has been added to the equipment of the investigator: *i.e.*, the psycho-physiological deception test, although it is better known to the public as the “lie-detector.” With this technique it is possible to establish guilt or innocence in a comparatively short period, thus avoiding the long, wearisome hours given to the examination of persons who are under suspicion.

The technique of the deception test consists primarily in securing a blood pressure curve, taken synchronously with a respiratory and a time curve. In practice, the suspect is seated on a chair, a cuff is then strapped on the upper part of the arm for the purpose of recording the blood pressure and a rubber tube is hooked round the chest for recording the respiration. After adjusting the blood pressure device, the instrument is set in motion and permitted to run for a few minutes in order that the normal reaction for this individual may be obtained. The expert conducting the investigation then follows this by an introductory statement to the effect that the suspect is being subjected to a test to determine his guilt or innocence and, further, that taking the test is optional for him. A few questions are then asked which require an answer of “yes” or “no,” the correct answers being known to the expert before they are given. The graph, which includes the brief run without questions and reactions to the preamble and indifferent questions, is used for comparison with the later record obtained when questions relating to the crime under investigation are asked of the suspect. Results obtained thus far indicate that the deception test (*q.v.*) affords a convenient and reliable method for detecting deception.

Identification.—Criminal investigation and criminal identification go hand in hand. The identification expert is the foremost ally of the investigator. Occasionally the identification expert furnishes information to the investigator regarding the identity of the person who committed the crime as well as supplies the evidence that serves to convict the offender after his apprehension. The duties of the identification expert are:—

(1) To ascertain identification of the perpetrator of the crime prior to his apprehension (a) by the use of the alphabetical index when the name of the offender is known; (b) by photograph when the criminal has been seen by his victim or by witnesses; (c) by the *modus operandi* of the criminal; (d) by the handwriting of the criminal; (e) by finger impressions left at the scene of the crime.

(2) To ascertain identification of offenders after arrest (a) by the alphabetical index; (b) by a photograph, where no finger-prints have been taken; (c) by the *modus operandi* system connecting the arrested criminal with numerous other crimes; (d) by comparison of the criminal's handwriting with documents connected with criminal offences; (e) by finger impressions of the criminal found at scenes of crimes committed by him, of which he was not suspected by the investigator; (f) by the ten-digit finger-print system when the offender has been previously recorded in the bureau.

Criminal identification may be said to have originated with the branding of criminals. In 1487, it was enacted in England that every person convicted of a felony in which benefit of clergy was admitted should be branded on the brawn of his thumb; with an M if his case was murder and with a T if it was theft. Tattooing was also used in marking criminals.

A name registry of convicted criminals marks the beginning of modern criminal identification methods. This registry has served officials effectively and is still used in an amplified form. Quite early, however, a name registry was found to be comparatively worthless for the purpose of identifying habitual and migratory criminals because they changed their names or residence with every arrest.

SCIENTIFIC ENQUIRY

The earliest scientific method used for the purpose of criminal identification was photography. In 1850 photography made rapid advances with the introduction of the collodion process, for then untrained persons could easily learn how to take and develop photographs. The result was that photographs of criminals were taken in various countries. When photography was introduced, it was believed that this means of identification would furnish a solution to the problem which confronted the law enforcement officials. In the course of a few years, however, the collection of criminal photographs grew so large that it became physically impossible to locate a previous record of the offender. Experts spent weeks in an effort to identify a person suspected of having a prior record. England then started a tattoo registry to supplement the photograph record. This, too, became unwieldy and yielded comparatively small results, considering the enormous amount of labour expended in maintaining and searching the registry.

Bertillon System.—Many unsuccessful methods were devised to break up and make serviceable the huge collection of photographs and finally Dr. Alphonse Bertillon, chief of the identification bureau in Paris, invented the signaletic system in 1882. This system is divided into three parts: (1) the anthropometric signalment, which consists in measuring some of the characteristic dimensions of the bony structure of the body, under prescribed conditions and with the utmost precision; (2) the descriptive signalment, which is the observation of the shape and movements of the body, and even the most characteristic mental and moral qualities; (3) the signalment by peculiar markings, which is the observation of peculiarities of the surface of the body resulting from disease, accident, deformity or artificial disfigurement, such as moles, warts, scars, tattoo marks, missing or deformed members. The following measurements are taken:

Measurements of the body: Height (height of man standing) Reach (length of the outstretched arms from finger-tip to finger-tip) Trunk (height of man sitting).

Measurements of the head: Length of the head. Width of the head. Length of the right ear. Width of the right ear.

Measurements of the limbs: Length of the left foot. Length of the left middle finger. Length of the left little finger. Length of the left forearm.

Bertillon's system has been discarded by most police departments, but his descriptive methods are used by investigators because no better scheme has yet been devised for furnishing a minutely descriptive, verbal portrait of an individual. Colour of eye, shades of hair and complexion, shape of the forehead, nose and ear, and build of the criminal are subjected to a rigorous but simple classification scheme. Other complementary features included in the verbal portrait are a description of the lips and chin, the general contour of the head, including profile and face, the various modes of implantation of the hair, the beard and the eyebrows, the shape of the eyelids, the form and size of the eyebrow and the orbit, the mouth, the wrinkles and furrows of the face, the expression of the physiognomy, also various kinds of information relative to the general aspect of the subject and the visible marks, scars, moles and missing or deformed parts of the anatomy.

Finger-prints.—Dactyloscopia, the science which deals with the identification of individuals through their finger-prints, was removed from the realm of theory and made practical by Juan Vucetich of Buenos Aires in July 1891. A finger-print registry was established by him at La Platte on Sept. 1 of the same year to supplement the Bertillon system, which at that time was found to be wanting in many respects. Later the Bertillon system was eliminated.

A theoretical classification of finger-prints was presented to the University of Breslau by Prof. John Purkenje in 1823. This classification was the foundation of all the theoretical and practical

work that followed. Purkenje divided finger-prints into nine basic types. In 1888 Francis Galton made an additional and distinct contribution to the science of dactyloscopia by analysing and counting the papillary ridges in the bulbs of the fingers. His method has been followed by all later investigators. Application of one or two digital impressions as a substitute for signatures and as a means for identification, was made as early as 1858 by Sir William Herschel, head of the Indian Civil Service district of Hooghly, Bengal. The governor-general, in June 1897, directed that the E. R. Henry finger-print system of identification should be adopted in British India. In 1892 the first identification was made from bloody finger-prints left at the scene of a crime. In that year Francisca Rojas, an Argentinian, who had charged a neighbour with the murder of her sons, was found to be the assassin. The proof of her guilt was established by the bloody impressions left on the jamb of her door.

Vucetich divides all finger-prints into four primary groups. The first group consists of all those designs formed by curved ridges without angles or deltas, the ridges extending from one side of the finger to the other without recurving. They are called arches. The second group has the angle or delta situated at the right of the person observing it and the directive lines have their exit toward the left. They are called internal loops. The third group has the delta situated at the left of the person observing it and the direction of the lines runs toward the right. They are called the external loops. The fourth group has two deltas and the directive lines circumscribe circular figures. They are called whorls.

For classification purposes the arch, internal loop, external loop and whorl are denominated respectively A. I. E. W. for the thumbs; and 1. 2. 3. 4. for the fingers. Accordingly a hand containing internal loops in the ten fingers would classify I 2222—I 2222. The total possible primary combinations of the Vucetich system number 1,048,576.

Primary classification will suffice for the ordinary collection of finger-prints but Vucetich provides for subdivision of large groups in the following classification scheme. Arches: natural arch, 5; internal inclination, 6; external inclination, 7; tented arches, 8. Internal loops: natural, 5; converging ridges, 6; approximating central pockets, 7; irregular loops, 8. External loops: natural, 5; converging ridges, 6; approximating central pockets, 7; irregular loops, 8. Whorls: natural, 5; lateral pockets and twinned loops, 6; elliptical whorls, 7; accidental or irregular types, 8.

E. R. Henry divides all impressions into four types, namely: arches, loops, whorls, composites. (1) In arches, the ridges run from one side to the other without backward turn or twist and, ordinarily, have no delta. (2) Loops have at least one recurving ridge and at least one ridge between the delta and core. In ulnar loops the ridges recurve toward the little finger; in radial loops, the ridges recurve toward the thumb. (3) Whorls have at least one ridge making a complete circuit. (4) Composites are patterns having characteristics of two or more of the foregoing patterns.

The primary classification is arrived at by pairing off the fingers. Beginning with the right thumb they occur on the finger-print sheets thus: first pair, right thumb and index are given a value of 16; second pair, right middle and ring fingers, a value of 8; third pair, right little finger and left thumb, a value of 4; fourth pair, left index and middle fingers, a value of 2; fifth pair, left ring and little fingers, a value of 1; the first of each pair counting as the denominator and the second as the numerator. Only whorls or composites are given a valuation. One is added to the numerator and denominator, thus giving 1 over 1 where all patterns are arches or loops, and 32 over 32 where all patterns are whorls or composites.

Arches, tented arches, radial or ulnar loops occurring in either of the index fingers compose the sub-classification, the right index finger being the numerator and the left index the denominator.

A group classification is obtained by tracing the ridges in the whorls and counting the ridges in the loops of the index and middle fingers of both hands. Arches, tented arches and radial loops, being of relatively infrequent occurrence, are always noted in the formula.

Owing to the fact that it was difficult to discover the identity

of a person from a single finger impression left at the scene of the crime, even though the criminal's finger-prints were filed in the identification bureau, identification experts decided to give attention to the classification of single finger-print impressions. Oloriz, in Spain, was a pioneer in this field, followed by Jorgensen in Denmark, Collins in England, and Crosskey and Larson in the United States. These investigators have succeeded in producing single finger-print systems that are operating in various countries. Their formulae make it possible to identify a criminal from a single digital impression which may be left behind by the criminal, provided that the offender's prints have been previously registered and are in the single finger-print file.

Larson System.—The following is a brief outline of the Larson system. The pattern to be identified is (1) classified according to the gross configurations of characteristic formations; arches are divided into seven types; loops, 9; whorls, 6; twinned loops and lateral pockets, 4; and accidentals, 13. (2) The inclination of the pattern—i.e., the pattern slopes to the right or left, or has no inclination at all—divides all types into three sub-divisions. (3) The pattern is then classified according to the configuration of the ridges which constitute the core. (4) The ridge surrounding the core—called by Larson, the "envelope"—is classified according to its peculiarities or appendages. (5) The first ridge in front of the delta is classified according to its characteristics, such, for example, as abrupt terminations, tented, composite characteristics, dotted ridges, forked, natural or recurving. (6) The delta is then classified according to two basic types: open and closed. These two types are further divided into eight sub-types. (7) The final differentiation is reached by ridge counting and ridge characteristics. Larson says: "The pattern is split into natural divisions and each division may be treated independently. Thus a pattern may be searched for according to type; core; envelope; delta; ridge count; or ridge characteristics."

Factor	Class 1	Class 2	Class 3
I. Form If eyed forms are present classify as No. 3; otherwise according to whether angular or rounded.	Angular	Rounded	Eyed
II. Skill Legibility, symmetry and pictorial aspect considered.	Poor	Medium	Good
III. Connections If small letters show disconnection classify as No. 3; otherwise according to whether capitals are connected or disconnected.	Capitals connected	Capitals disconnected	Small letters disconnected
IV. Shading Determined by difference in width of the lightest and heaviest strokes.	Light	Medium	Heavy
V. Movement Finger movement lacks freedom, is slow and usually shaded; forearm shows speed, force, dash, freedom and little shading.	Finger	Compound	Forearm
VI. Embellishment Determined by degree of ornamentation.	Plain	Intermediate	Embellished
VII. Terminals Inclination of terminal strokes.	Upward	Horizontal	Downward
VIII. Slant Degree of slant above horizontal.	Less than 60 degrees	60 to 80 degrees	More than 80 degrees

Analysis of Handwriting.—Such a large amount of handwriting in the form of signatures on pawnshop and second-hand store books, hotel registers, writing found on worthless cheques, letters and documents of every character, is connected with criminal cases that it was necessary to find a means of classifying this valuable material. Dr. Hans Schneickert in Germany, several Austrian experts, and Lee and Abbey in the United States have contributed to this important method of identifying criminals.

The chart used by Lee and Abbey is in the adjoining column.

Modern identification bureaux, or divisions, maintain elaborate indexes giving the alphabetical arrangement of names according to the directory guide system; the *modus operandi*, arranged either by index guides or decimal system; a special marks file, in which are kept the anatomical peculiarities that assist in identifying individuals; and the ever-present "rogues' gallery."

In some cities the "rogues' gallery" photographs are pasted in books kept in numerical order; in others, they are kept in books but filed according to crime; and in still others they are placed in books and segregated according to crime, then according to hair colour, eye colour, height and weight. Some departments use the Kardex system and file photographs according to the *modus operandi* of the criminal, and then by the English descriptive method. Others have large wall leafs on which are placed the photographs of active operators, and these are frequently arranged according to description of the individual and his *modus operandi*.

While it is true to-day that not many identifications are made by photographs, they are yet sufficient in number to warrant their continuance as a means of identification.

INVESTITURE, the formal installation into an office or estate, which constituted in the middle ages one of the acts that betokened the feudal relation between suzerain and vassal. The suzerain, after receiving the vassal's homage and oath of fealty, invested him with his land or office by presenting some symbol, such as a clod, a banner, a branch, or some other object according to the custom of the fief. The sword and sceptre, emblematic respectively of service and military command and of judicial prerogatives, became the usual emblems of investiture of laymen. The word investiture is later than the 9th century; the thing itself was an outcome of feudal society.

It is in connection with the Church that investiture has its greatest historical interest. The Church quite naturally shared in feudal land-holding; in addition to the tithes she possessed immense estates which had been given her by the faithful from early times, and for the defence of which she resorted to secular means. The bishops and abbots, by confiding their domains to laymen on condition of assistance with the sword in case of need, became temporal lords and suzerains with vassals to fight for them, with courts of justice, and in short with all the rights and privileges exercised by lay lords.

Investiture of ecclesiastics by laymen had certain serious effects which were bound to bring on a conflict between the temporal and spiritual authorities. In the first place the lay authorities often rendered elections uncanonical by interfering in behalf of

some favourite, thereby impairing the freedom of the electors. Again, benefices were kept vacant for long periods in order to ensure to the lord as long as possible the exercise of his regalian rights. And, finally, control by temporal princes of investiture, and indirectly of election, greatly increased simony. The main investiture struggle with the empire took place when Hildebrand became Pope Gregory VII. (q.v.). To Gregory it seemed intolerable that a layman should invest a churchman with the symbols of office. To the emperor Henry IV. it was highly undesirable that the advantages and revenues accruing from lay investiture should be surrendered; it was reasonable that ecclesiastics should receive investiture of temporalities from their temporal protectors and suzerains. Although the full text of the decrees of the famous Lenten synod of 1075 has not been preserved, it is known that Gregory on that occasion denounced the marriage of the clergy, excommunicated five of Henry IV.'s councillors on the ground that they had gained church offices through simony, and forbade the emperor and all laymen to grant investiture of bishopric or inferior dignity. The struggle was complicated throughout its course by political and other considerations; there were repeated rebellions of German nobles, constant strife between rival imperial and papal factions in the Lombard cities and at Rome, and creation of several anti-popes, of whom Guibert of Ravenna (Clement III.) and Gregory VIII. were the most important. Final settlement of the struggle was retarded, moreover, by the question of the succession to the lands of the great Countess Matilda, who had bequeathed all her property to the Holy See, Henry claiming the estates as suzerain of the fiefs and as heir of the allodial lands. The efforts of Gelasius II. to settle the strife by a general council were rendered fruitless by his death (1119). At length in 1122 the struggle was brought to an end by the concordat of Worms, the provisions of which were incorporated in the eighth and ninth canons of the general Lateran council of 1123.

In France the course of the struggle was somewhat different. As in the empire, the king and the nobles, each within his own sphere of influence, claimed the right of investing with ring and crozier and of exacting homage and oaths of fealty. The struggle, however, was less bitter chiefly because France was not a united country, and it was eventually terminated without formal treaty. The king voluntarily abandoned lay investiture and the claim to homage during the pontificate of Paschal II., but continued to interfere with elections, to appropriate the revenues of vacant benefices, and to exact an oath of fealty before admitting the elect to the enjoyment of his temporalities. Most of the great feudal lords followed the king's example, but their concessions varied considerably, and in the south of France some of the bishops were still doing homage for their sees until the closing years of the 13th century; but long before then the right of investing with ring and crozier had disappeared from every part of France.

England was the scene of an investiture contest in which the chief actors were Henry I. and Anselm. The archbishop, in obedience to the decrees of Gregory VII. and Urban II., not only refused to perform homage to the king (1100), but also refused to consecrate newly-chosen bishops who had received investiture from Henry. The dispute was bitter, but was carried on without any of the violence which characterized the conflict between papacy and empire; and it ended in a compromise which closely foreshadowed the provisions of the concordat of Worms and received the confirmation of Paschal II. in 1106. Freedom of election, somewhat similar in form to that which still exists, was formally conceded under Stephen, and confirmed by John in Magna Carta.

Many documents relating to the investiture struggle have been edited by E. Dümmler in *Monumenta Germaniae historica, Libelli de lite imperatorum et pontificum saeculis xi. et xii.* (3 vols., 1891-1897). See Ducange, *Glossarium*, s.v. "Investitura."

INVESTMENT. An investment may roughly be defined as the depository of savings. The term is usually applied to money, but strictly speaking it is equally applicable to all kinds of property, such as land, buildings and furniture. In short, the whole of an individual's property, including the debts due to him at any time, may be described as his investments.

In considering the question, a broad distinction must first be drawn, between "forced" or "unconscious" and "voluntary" or "conscious" investment. Forced investments arise in several ways. The chief is that every business man has to grant credit to his customers, and most workers receive their wages or salary "in arrears," that is after they have performed their week's or month's work. Money thus due is clearly part of each man's investments, and the amount thus "invested" is dependent not on his voluntary act, but on the customs of the trade or on his terms of employment. Before considering voluntary or conscious investment, it is necessary to examine the various motives which induce saving and govern the choice of investments. First and foremost comes the desire to provide for old age, sickness and other emergencies. Here safety is the paramount consideration, and the interest on the investment need not be taken into account. To illustrate this, £100 may be a godsend in case of an emergency, but until it is required, it makes little difference to the owner's annual income whether it is earning 2½% on deposit in the bank, or 7% in some highly speculative mining shares. Next comes the question of interest, and this arises from the desire of the individual to use his savings to augment his income. In general, the rule is "the greater the yield, the greater the risk," and the application of this rule and the weighing-up of capital safety and income is one of the chief problems of the investor. Next comes the desire for that will o' the wisp, "capital appreciation," when the investor hopes that his property will rise in value. Here the distinction between investment and speculation becomes very thin. Finally come a whole host of motives. One man invests his money in his own business because it is expanding, and will gain for him fresh profits and fresh prestige; another in his business because it is going downhill, and he has still to learn not to throw good money after bad, and another in real and personal property of one kind and another, simply because of the satisfaction the possession of such property will give him. Every investor must bear in mind one general warning. Every investment demands eternal vigilance on the part of the holder. Consols, which, before the World War, were regarded as the soundest of stocks, are themselves a striking warning to the unwary. In 1896 they were quoted at 110½, by 1907 they had fallen to 84, and by 1913 to 73½. Then came the War, and the inflation period, and by 1920 they had fallen to a minimum of 43½. By the end of 1927 they had recovered to 56. It is true that the interest remained constant throughout this period at a steady 2½%, but £2 10- would buy much less in 1927 than in 1896, so that even this stability possesses a certain unreality.

General Rules.—There are certain general rules governing the course of trade and finance which should be known to every investor. The first has already been quoted, but is repeated again

so as to be presented in compact form with the remainder:—

- (1) The greater the yield, the greater the risk.
- (2) Where the rate of interest is fixed, a high yield means a low price; therefore, as the risk increases, the price falls.
- (3) When money is scarce, interest rates rise, and prices fall.
- (4) Rising commodity prices mean active trade and high profits, but ultimately scarce money; and falling prices the reverse.
- (5) The capital value or yield on a share is not only its "money" value or yield, but depends also on the purchasing power of money. This and the preceding rule must be read together.
- (6) When trade is active and money in demand to the point of scarcity and high interest rates, buy consols, war loan and similar gilt-edged fixed-interest stocks, for these will be cheap under rule (2) and will improve under the second part of rule (4).
- (7) When trade is dull and money plentiful, buy ordinary shares whose value rises and falls with the course of business; these, provided the company is sound, will be cheap under rule (2), and will improve under the first part of rule (4).
- (8) Last and most important of all, lay a solid foundation. Life insurance comes first, and see that insurance is added to if the cost of living rises or the assured's standard of life improves. A life policy for £500 taken out in 1896 when living was cheap, is only partial protection in 1928 when prices have approximately doubled. If prices rise, more insurance must be taken out to maintain the same degree of protection.

Next in turn for the British investor come savings certificates. Even at 16s./— these are an attractive investment; they are safe, realizable, independent of market fluctuations and free of income tax. These should be bought up to the limit. After that, the investor can consider other openings. These are discussed in detail below.

and there is always the risk of the property standing vacant for a time. Again rents can vary just as much as an "ordinary" dividend. Every time a lease expires, a fresh agreement has to be made, and it is not always the tenant that is the loser. Over and above this comes one important point. Land and house-room are a universal necessity, and the result is that so far as public opinion and legislation are articulate, they are more anxious that the tenant should have adequate housing at a rent he can afford, than that the landlord should earn on his property a net return commensurate with that to be obtained elsewhere. This particularly applies to the smaller class of houses, and the war and post-war Rent Restriction Acts in England are an example of this point. Those who before the War owned houses which were exempt from restriction, found they had an investment with all the advantages of an ordinary share, while those whose property came below the line, found it had many of the disadvantages of a fixed-interest stock. In short, when money depreciates violently and prices rise, the landlord of small property must expect to be debarred by law from raising rents accordingly. Provided that he can raise his rents enough to equal any increase in maintenance costs, so that his net rent remains unchanged, restriction is not inequitable. A landlord has no greater right to claim a larger net rent because of a rise in prices than the holder of 2½% consols has to claim that in future the Government should pay him 4% or 5%. Sufficient has been said to show that house-property is a dangerous possession for the ignorant investor.

British Government and Corporation Stocks.—The first of the rules previously enunciated stated that "the greater the risk, the greater the yield." Here the risk is negligible, so all the investor has to watch is the general rise and fall in interest rates. Rules (3) to (7) inclusive, should be a sufficient guide, but the accompanying table of post-war prices will illustrate their incidence.

Variations in Certain British Gilt-edged Securities 1919-27*

Stock	Nominal interest	1919	1920	1921	1922	1923	1924	1925	1926	1927

*Redeemable 1930-50. †4th Series, redeemable 1929.

Land, House-property, etc.—Here is often an obvious case of forced investment, viz., that of the man who has to buy his own house or farm, or else clear out. He, too, often has to pay a forced price. If it is any consolation, he must realize that in post-war days, purchase is often the only means of getting a decent home. Two words of warning may be uttered in this connection. The first is contained in the explanation of a farmer for his action in warning off the local hunt: "I've changed my landlord, and the new one's far harder on me than the old. My new landlord is myself!" The other is that in buying, or making an offer to buy, he must count all the costs, including stamp duties and legal charges. If he buys through an estate agent, it is customary for the vendor to pay the agent's commission, which is considerable on a big transaction. The customary legal scale of charges for both buyer and seller is heavy, and it is always well to make a bargain in advance with the solicitor acting in the matter. As regards land and houses as a medium for voluntary investment, here the investor becomes the landlord. He must realize at once that property of this kind demands special care and knowledge from its owner. Repairs, maintenance, ground rents, rates, legal charges all levy a toll upon the gross rent,

Two short-dated securities have been included. These are both redeemable at 105, and so their market price gradually approximates towards this point. The level and trend of interest rates are also included in the table. The reader can trace for himself the connection between interest rates and prices. He can also see when it was "a good time" to buy or to sell. Finally, he can see that even gilt-edged stocks are subject to wide price fluctuations. The years 1921 and 1922 in particular are commended to his notice.

Foreign Stocks and Bonds.—"The greater the risk, the greater the yield," and here a special risk enters. The interest and principal on foreign stocks are often payable in foreign currency, and even when payable in sterling, the Government concerned has to buy the sterling needed for the service of the debt. In the first case, the interest received by the British holder varies with each fluctuation in exchange, for the interest on Frs. 1,000 5% French Rentes is 50 francs, whether a franc is worth tenpence, twopence or a penny. Exchange fluctuations govern the sterling interest, and also the market price. This is illustrated by the table which will be found on the next page relating to 5% Rentes:

Year	Franc exchange	Sterling interest on Frs. 2,500	Sterling price of Frs. 2,500	Yield (at "middle" price)
1921 . . .	Fr. 51.6	£2. 8. 6	33-48	6 ⁵ / ₈ %
1922 . . .	Fr. 54.0	£2. 6. 4	25-49	6 ³ / ₈ %
1924 . . .	Fr. 84.5	£1. 9. 6	18-28	6 ⁴ / ₈ %
1926 . . .	Fr. 150.0	£1. 16. 8	7-14	7 ⁹ / ₈ %
1927 . . .	Fr. 125.0	£1. 0. 0	13-21	5 ⁹ / ₈ %

The "risk" here was the collapse of the franc. This increased up till 1926, and then sharply receded. Hence the rise and fall in the yield. The London market price was determined jointly by the sterling interest and the yield required by the market to compensate for the risk.

Industrial Stocks.—These fall into three main categories: debentures, preference shares and ordinary shares. Each is subject to wide fluctuations, and the buyer should remember this and judge by their past record, whether the shares he is contemplating purchasing stand at a "top" or a "bottom" price. Debentures are governed both by the level of interest rates, and by the risk of loss or default, and this risk is judged usually by the fortunes of the company's shares. Thus the passing of the ordinary dividend will cause a slight fall, and the passing of the preference dividend a heavier fall in the company's debentures. The issue of further (and especially of prior debentures) may also weaken existing debentures, unless it is clear that the company is obtaining the fresh money to finance new and remunerative business. The price of ordinary shares reflects many things, such as current dividends, future dividends, the possibility of bonus share issues or the existence of accrued losses. These are dealt with later. The preference share comes half-way in between. In some ways it has the disadvantages of both. It also is dealt with later. Holders of all three classes of securities should watch price fluctuations, but not be unduly elated by a rise, or dismayed by a fall. A sound share is usually worth holding.

if things prosper, the gains go to the ordinary shareholder. The preference shareholder's measure of protection is clearly the size of the ordinary capital and ordinary dividend. If 100,000 £1 preference shares have 100,000 £1. ordinary shares behind them, and the usual ordinary dividend is 10%, the "capital" protection is £100,000, and the "dividend" protection is £10,000. If the ordinary shares are 100,000 of 1s. each, and the ordinary dividend is 50%, the "capital" protection falls to £5,000, and the "dividend" protection to £2,500, both of which figures are dangerously small. In other words, it will not take much of a loss to encroach upon preference dividends while the smaller ordinary capital will receive just as many plums as before.

Ordinary shareholders receive what is left out of profits, after debenture interest, preference dividend and allocations to reserve have been made. When times are bad, they get nothing, and when they are good they may receive much. Many companies try and maintain a constant ordinary dividend, and in good times declare a "cash bonus" which is really an extra dividend. One of the great merits of ordinary shares is that a proportion of the profits are every year "put back" into the business by the directors of the company. This is necessary if the business is to progress, but it also means that a proportion of the ordinary shareholder's income is forcibly saved for him and re-invested by his directors. Hence his shares are steadily appreciating in value all the time. The issue from time to time of bonus shares from reserves is simply the outward and visible sign of this continuous progress. A bonus issue in itself adds nothing to the value or earning power of the property, and the reason why the market hails it as a bull point is that it marks a definite stage in the company's progress, releases to the shareholder some of his forced savings, and is considered by the ignorant to be of the nature of "receiving something for nothing."

The fundamental principle of debentures, preference and ordinary shares, is that the holder of the last-named is first in line for both the "kicks" and "half-pence" distributed by fortune. He also exercises full control over the company, and the debenture and

Debentures represent money lent to a company, and principal and interest must alike be met, whether or not any profits are earned. Default is equivalent to an act of bankruptcy, so the way to regard them is whether or not the company possesses the required resources. Special points to remember are that as a rule trade creditors rank ahead of debenture-holders, and in many cases a company has the power to issue new debentures ranking ahead of the old ones. These points should be investigated by the prospective purchaser. Preference shareholders are part owners of the business. They only receive a fixed dividend, but in return have first claim to divisible profits, and first claim to repayment on the liquidation of the company. Thus, if things go wrong, the ordinary shareholder has to bear the brunt of the attack, while,

preference shareholder can only intervene when surplus "kicks" start coming his way. It must be realized that this gives great scope for the unscrupulous ordinary shareholder to display his ingenuity. Thus, he can distribute two years' profits in advance to himself by a suitable manipulation of the accounts, and then explain to the others that the company is insolvent and all must make sacrifices. Conversely, he can by a fraudulent conservatism, write down some of the assets to vanishing point, report insolvency, buy up the preference shares cheap, and then restore the assets (and the preference shares) to their true value. Nor need debenture and preference shareholders' rights count for much. They can always surrender their rights, and when the voluntary surrender of their rights is put before them as the only alternative

to bankruptcy, it is hard for the holder to resist.

There are too many cases where a company starts with, say, £10,000 in £1 preference and £10,000 in £1 ordinary shares. A good period ensues, and 10,000 more £1 ordinary shares are issued from reserve by way of bonus, the future being partially mortgaged in the process. Then comes a slump, a loss of £10,000 piled up, and eventually dealt with by writing the preference shares down to 15s. and the ordinary shares down to 12s. 6d. On the face of it, the ordinary shareholder has dropped 7s. 6d. to the preference shareholder's 5s. In reality, adding together the bonus issue and the reconstruction, the ordinary shareholder has taken 5s. from the preference shareholder.

A post-war development, which has nothing to commend it, is the splitting of a company's capital into £1 preferred and 1s. deferred shares. It has already been shown how this weakens the bulwark between the preferred shareholder and disaster. It is also a means of reserving the "half-pence" for the deferred shareholder, and sharing the "kicks" equally between the two classes. Take this case:

100,000 6% Preferred shares of £1 each	£100,000
100,000 Deferred " " 1s. "	5,000
Total capital	£105,000

The following table shows how the "half-pence" are distributed:

Total dividends	£20,000	£15,000	£10,000	£6,000
Pref. dividend at 6%	£6,000	£6,000	£6,000	£6,000
Def. dividend (amount)	£14,000	£9,000	£4,000	Nil.
Def. dividend (rate)	280%	180%	80%	Nil.

Say these were four years' consecutive results. The deferred shareholders have received £27,000 on their original holding of £5,000, that is, their capital back and £22,000 to boot. They can ask the preferred shareholder to be brave in facing bankruptcy with them with perfect equanimity. Nor is this the whole indictment against the shilling deferred share. In 1927 when it first appeared in Great Britain in obnoxious quantities, the vendors or promoters of a company would often keep half the deferred shares for themselves. The public would be graciously allowed to buy the other half, provided that they also bought all the preferred shares. This was a reincarnation of the founders' share with a vengeance. To show the market's appreciation of the relative worth of £1 preferred and 1s. deferred shares, the following examples may be quoted. The names are suppressed for obvious reasons:

	Share and issue price	Price	Rise or fall from issue price %
Company A	£1	18/-	- 10
" "	1/-	9/-	+ 800
" B	£1	12/6	- 37½
" "	1/-	3/9	+ 275
" C	£1	16/9	- 16½
" "	1/-	7/-	+ 600
" D	£1	£1	..
" "	1/-	12/6	+ 1,150

These figures speak for themselves.

Reading the Balance Sheet.—Every shareholder should be able to read the balance sheet of his company. He must remember that every figure in it represents only the estimates of the board and their advisers—thus, "plant £200,000" and "stocks £50,000" are obviously estimates, and as more intangible items, such as profits and reserves, are deduced from these first, they are equally only estimates. There are three rough tests a shareholder can apply to a balance sheet: (a) What are the liquid assets of the company—these equal cash plus any investments in "trustee" stocks plus debtors minus creditors and bank overdraft? If they are diminishing from year to year, the shareholder is put upon his guard. (b) What is the net value of the property, i.e., assets (less accrued losses, preliminary expenses, etc.) less creditors? Again, is this increasing? (c) Are the directors putting at least £1 to reserves for every £3 distributed in capital? If not, why not, for this is a fundamental principle of sound company finance.

The first two points are illustrated by this balance sheet:—

	£		£
Preference shares	100,000	Plant and stocks	350,000
Ordinary shares	200,000	Debtors	25,000
Reserve fund	150,000	War loan	50,000
Creditors	20,000	Cash	45,000
	£470,000		£470,000

Liquid assets are, therefore, £25,000 + £50,000 + £45,000 - £20,000 = £100,000. The total value of the property is £470,000 - £20,000 = £450,000. Deducting preference shares, this is equivalent to 35s. per £1 ordinary share.

The rate of interest on debentures and preference shares is fixed; even if it falls into arrears, the arrears must be made up in the case of debentures and "cumulative" preference shares. So the potential investor must consider chiefly the risk of default. As regards ordinary shares, he must weigh the risk of no dividends against the chance of high dividends and cash bonuses. Capital appreciation and depreciation are dependent partly on the level of market interest rates, but mainly on the view taken as to the future of the company in particular and the industry in which it operates as a whole. The investor, therefore, must watch these points, accepting all rumours with a large grain of salt. Over and above the fluctuations of trade, ordinary shares in a company with a proper reserve policy should steadily appreciate in value. It is this that accounts for the new theory that ordinary shares are a "safer" investment than gilt-edged stocks. As regards wide changes in the purchasing power of money, to a large extent the ordinary share comes out best of all. When prices are rising, profits and dividends also rise, and the shares appreciate in money value to an amount roughly equivalent to the decline in money's purchasing power. The important point to watch is that the company uses this period to build up a good reserve fund. The reason for this is that a fall in prices operates so unevenly upon a trading company as to involve it temporarily in heavy loss. Once it survives this, the contraction in the money value of its shares is compensated for by the higher purchasing power of money, but this is no consolation to the shareholder if the company fails altogether.

Practical Hints.—One or two practical hints may be given in conclusion:—

(1) As already urged, the small investor should first insure his life for an adequate amount, and then buy (in Britain) savings certificates up to the limit of £500.

(2) The investor who wants to go further, should spread his money between gilt-edged stock, some sound debentures, and ordinary shares with a "good history."

(3) With the return on gilt-edged stock at 4½%, do not aim at more than 5½% on debentures or 7% on ordinaries.

(4) Avoid foreign and specialized shares and also new issues, unless you have personal knowledge of their peculiarities.

(5) Deal through a bank or member of a recognized stock exchange.

(6) Do not put too much into one company, or even one industry. To spread investments is to minimize losses.

(7) Watch your investments, and continue to watch. (See also STOCK EXCHANGE; MONEY; BALANCE SHEET.) (N. E. C.)

The United States.—American investment habits are conditioned by the newness of the country and the venturesomeness of the people. Securities which give a semblance of the safety of an investment and at the same time offer the prospect of profit of a speculation, have been in growing favour. Bonds which are convertible into stock, bonds with stock purchase warrants attached, preferred shares which are convertible into common stock and preferred or so-called A shares which participate in profits under specified conditions with the common shares, constitute the chief banking devices for combining investment with speculation. To an increasing extent, the American investor, desiring to have his cake and eat it too, has been indulging in speculative investments.

Before the World War, it was commonly conceded that shares were for speculation and bonds for investment. It is now held that well selected common shares are suitable for long term invest-

ment for individuals who are less concerned with getting back a particular number of dollars than with assuring themselves of given purchasing power or command over commodities in the future. In a steadily growing country, such as the United States, a good case can be made out for the equities—or stock interest—in well managed companies, which perpetually increase their stake in the nation's business.

The growing preference for common stocks for long-term holding was rationalized as a new investment philosophy by Edgar Lawrence Smith in his volume *Common Stocks as Long Term Investments* and by Kenneth Van Strum in *Investing in Purchasing Power*. As investors show a disposition to turn from conservative bonds to more speculative stocks, there has been a growing recognition of the need of timely statistical data and analytical skill. Accordingly, the new profession of investment management has been springing up. Between 1924 and 1928, the American investor, desiring to invest by proxy through experts, showed widespread appreciation of the investment trust idea, a novelty in the United States. According to recent estimates, there were 208 investment trusts in the country, with total resources exceeding \$1,000,000,000. Such agencies, which differ widely among themselves, take the form of corporations more frequently than of common law trusts. Such agencies have for the most part built up portfolios consisting largely, if not entirely, of stocks instead of bonds. Moreover, investment counsellors, who sell only advice, have tended to favour a balanced investment list, consisting of stocks as well as bonds.

The amateur, or lay buyer, has become in the last decade an increasingly important factor in the American investment market. Before the war, it was estimated that there were only 400,000 bond buyers in the country. The Liberty Loan campaigns during the World War gave millions of Americans their first experience as security owners. There is no reliable record of the number of security owners in the United States, though estimates run upwards of 10,000,000. Not only have American governmental agencies and private corporations dipped deeply into the reservoir of savings, but an increasing array of foreign governments and foreign private business enterprises have borrowed funds in this market. New York city has accordingly become a world financial capital sharing honors with London. In 1928 New York city stood pre-eminent as a lender of long term capital, whereas London retained the primacy in financing short term foreign trade operations.

The New York money market has become increasingly cosmopolitan in character. The American investor, traditionally provincial in his tastes, gradually developed a wider outlook, and began to buy foreign issues, their higher rate being usually the attracting feature. Also outside of New York city investment banking facilities have been enormously expanded. The South and West, which before the war were virtually without local agencies for cosmopolitan investment, were covered with a network of local investment bankers and branches of nation-wide organizations. Individuals in the hinterland, who had formerly invested surplus funds almost exclusively in farm and urban real estate mortgages, began to diversify their risks. Financial advertising developed enormously in quality and quantity. Recent broadening of activity reflects, in part, the carrying of ticker facilities to parts of the country hitherto uncovered, particularly in the South, the Southwest, the Far West and in Canadian provinces. As recently as 1915, there were only 2,000 stock tickers in the country, compared with more than 7,000 in 1928. The expansion has been extremely rapid since the beginning of 1927.

In American practice, there is a sharp distinction between investing by individuals and investing by institutions. Although individuals are interested primarily in assuring purchasing power in the future, institutions, such as the savings banks and life insurance companies, with huge liabilities measured in dollars, rather than in purchasing power, are interested in assuring a specific number of dollars through their investment programmes. Accordingly, institutions for the most part favour bonds, which promise a given number of dollars at a specified date. The eligible investments for savings banks and life insurance companies are

clearly set forth in State laws. In general, the life insurance companies have more freedom than the savings banks. In some States, as also in Canada, insurance companies may purchase common stocks. The New York law respecting life insurance companies has recently been liberalized, permitting the purchase of the highest grade of preferred stocks as well as bonds, though common shares are still ineligible for life insurance companies in that commonwealth. With the growth of the power and light industry in the last decade, numerous States have made public utility bonds eligible for investments for trustees, savings banks and other institutions. Life insurance companies have consistently increased the proportion of their total investable funds placed in public utility securities.

An important new outlet for the investable funds of individuals has come through the conversion of hitherto privately owned close corporations into companies whose securities have been widely distributed. Department stores, chain stores, and other merchandising agencies have been conspicuous in this group. Holding companies have been set up, which have expanded rapidly through taking over local enterprises through an exchange of stock. The absorption has been profitable in most instances, for the public has usually placed a higher value on earning power when taken over by a large company, whose shares are readily marketable, than when reported by an obscure company, whose securities were illiquid.

Before the war, conservative investors favoured railroad securities, shunning all others as too speculative. They have got away from this notion, partly because the railroads, with their rates fixed by public regulatory bodies, have been less spectacularly prosperous than certain unregulated industrial corporations whose profits have been limited only by competition and the capacity of management. Seemingly, no successful product is too trivial or too unessential to win an investment following. As is usually the case when security prices are showing a long term upward trend, the security buyer exaggerates the importance as a determinant of value of current earning power and minimizes the effect of asset worth. (M. S. R.)

INVESTMENT TRUSTS. Although stock exchange dealings as we know them to-day, originated with the Dutch, the investment trust is essentially a British invention. In the early part of the 19th century, following upon the emancipation from Spanish rule of many portions of South America, there was a flood of foreign government and municipal issues in London, offering rates of interest that were very attractive compared with those obtainable on British Government loans. Numerous defaults occurred and within ten years only one-third of this total was in receipt of interest. A few years later followed the great railway boom, which was succeeded by the panic of 1847. The result was that British investors of all types were heavily hit, and in numerous cases ruined; but a comparatively small number of people were conspicuous exceptions. These were persons of considerable wealth who were in a position to command information and expert knowledge, and who had invested largely abroad. The need for some combination of smaller investors who, by co-operation, could secure similar advantages, was evident, and in 1863 (just after an act had been passed limiting the liability on shares in joint stock companies) two investment trust companies were formed in London. Several other companies of the same description were formed, and by the year 1886 these were sufficiently numerous to cause them to be grouped under the heading of "financial trusts" in the official list of the London Stock Exchange. The investment trust is a form of company that appears to have made a strong appeal to Scottish investors, and from the early beginnings of the movement Edinburgh has been the home of many such companies, most of them having been conspicuously successful.

Although not immune from the vicissitudes of the stock and share markets, investment trusts, as a whole, showed that they could pass satisfactorily through bad periods as well as good. It was not, however, until some years after the World War that a movement towards the creation of new investment trusts became apparent in Great Britain. This movement coincided

with one of much greater dimensions that started in the United States. A few new investment trusts were started in London, and older trusts began to form what might be termed sister investment trusts under the same management as themselves.

Conditions were certainly favourable to such institutions. The former belligerent countries, and the new States carved out of the central European empires, were in such need of capital that they were prepared to pay high rates. Most of these new loans were floated in New York, subsequent portions being placed in Amsterdam, London and Stockholm. Issues placed on foreign markets are out of the reach of the ordinary individual investor, but houses with international connections were able to avail themselves of the excellent investment opportunities thus afforded, and this conduced to the formation of new investment trusts, which were able to put their capital to profitable use.

170 British Investment Trusts.—At the beginning of 1929 the number of investment trusts in Great Britain was about 170 with an aggregate capital of approximately £250,000,000. At the same period the number of investment trusts in the United States was over 200 with a paid-up capital of about \$800,000,000—a surprising total when it is borne in mind that the first of these was formed so recently as 1921. Switzerland, Holland, France, Germany and Japan have all created investment trusts of recent years, but the tendency in these countries is more in the direction of what Americans aptly name, "specialty trusts," viz., companies investing primarily in the stocks of one class of undertaking, e.g., electric light, power and tramways, shipping, rubber and tea.

It is necessary to make a distinction between the investment trust and the finance company. The investment trust is an organization holding investments in common on behalf of its shareholders and distributing among the latter the income received. Emphasis requires to be placed upon the word "income," for the genuine investment trust never distributes profits made by the sale of its holdings; such profits, according to its statutes, must always be carried to reserve, and are, of course, invested to earn additional income available for distribution. This is the "acid test" of the investment trust. The title of a company is not a sure guide, for, unfortunately, there are many companies, British and others, incorporated under the name of investment trusts, which are but ordinary finance or holding companies. In Britain the inland revenue authorities themselves make this distinction, exempting genuine investment trusts from payment of income tax on "profits" from sales of securities, regarding them as associations of investors pooling their capital for safety and distributing income, that is, investment revenue only. A company that distributes any portion of such profits as dividends is regarded as an ordinary trading concern and pays tax on the total of its net profits, whether it calls itself an investment trust or not.

The ordinary type of British investment trust starts with an issue of capital divided as to 50% (sometimes 60%) in preference stock, and 50% (or 40%) in ordinary stock. After it has been established some time it issues debenture stock to the extent of perhaps its total share capital, so that roughly its capitalization is 20% ordinary stock, 30% preference and one-half debentures. By this method it obtains cheap *permanent* capital, an advantage which cannot be enjoyed by the private investor. The assets behind the debentures of soundly established investment trusts are so considerable as to constitute them practically gilt-edged stocks.

As a result of the excellent method of capitalization adopted by the British investment trusts the ordinary (or deferred, where the ordinary has a fixed dividend) stocks are frequently quoted at a price which represents a market capitalization in excess of what would come to them in the event of a liquidation, based upon the book value of the assets. The reason is that all the advantage arising from the cheap capital provided by the debenture and preference stocks accrues to the ordinary, either in the shape of a steady increase of dividend or bonus shares—or both.

Some British Examples.—The following table summarizes the position of a few typical British investment trusts at the beginning of 1929:

	Total issued deb. and share capital	Divs. on ordinary (or defd.) 1928	Price % Feb., 1929
	£	%	£
Alliance Trust Co.	6,699,805	25	573
British Investment Trust . . .	4,750,000	21	455
Industrial and General Trust . .	6,000,000	17	335
Investment Trust Corporation . .	6,375,000	20	407
Mercantile Investment and Gen- eral Trust Co.	6,500,000	16	302½

Co-operative investment trusts were started in 1923 and have made remarkable progress. This is a form of company run on exactly the same lines as an ordinary investment trust, but registered under the British Industrial and Provident Societies Acts, whereby the company is exempt from stamp duty on capital and income tax, but against these concessions may not permit any individual to hold more than £200 of share capital. Management is almost everything in the case of an investment trust, and in practice it has been found wise to stipulate in the rules that no single investment shall exceed a fixed proportion (usually 5%) of the share and debenture capital of the trust.

About one-half of the British investment trusts publish with their annual reports full lists of their investments. Others state the percentage held of different groups, but without specifying the individual investments. It is recognised in Great Britain that an investment trust may legitimately distribute income even where the capital is not intact, owing to depreciation of investments. This view was confirmed by judgments in the English courts in 1894. As the investment trust is precluded from distributing profits on the sale of securities, these go to build up a reserve, which is invested and immediately becomes revenue-producing, and herein lies the great strength of the investment trust principle. (A. E. DA.)

The United States.—The investment trust idea, which has decades of experience behind it in England and Scotland, is relatively new in the United States, yet by the end of 1928 there were more than 200 investment trusts in operation with total resources exceeding one thousand million dollars. An investment trust is an instrument for meeting the needs of the great class of small investors, who began for the first time to buy securities in large aggregate amounts at the time of the World War loans. Moreover, with America now in a leading world creditor position, the investment trust forms a useful medium for expert selection and diversification in foreign investments with which the average American investor is himself inexperienced.

The well-managed investment trust offers the advantages of co-operation and of guidance by specialists. Each is of distinct value. By joining with other investors and thus creating a large reservoir of capital, each participates in a fund which can be widely diversified in scores or hundreds of securities. The man with a \$1,000 surplus can get a participation in 400 securities, but, if he acted alone, he would have to be satisfied with one or, if he selected "baby" bonds, with ten.

Mere numbers are of distinct importance. Life insurance, for example, depends on them. If a group of six men were to insure themselves cooperatively against the hazard of death, their venture would be dangerously speculative and uncertain. However, if 60,000 men would insure themselves co-operatively the outcome would be certain. The risks would be so well diversified that the group would live in accordance with the established American tables on mortality. Similarly the investor who stakes his fortune in a handful of investment companies without sufficient diversification assumes needlessly grave hazards.

The classic American investment trust of the English type offers the actuarial benefits of heightened diversification through participation in a larger pool of capital than is available to the ordinary investor single-handed; second, the investment trust offers expert knowledge in the original choice of securities for the portfolio of the fund; and third, it assures continuous supervision by experts, in the light of changing conditions, of the investment portfolio. In addition to adapting the English type of investment

trust, American financiers have also created new patterns and variations. Even those trusts which are built on the English plan have set up far more restrictions on management.

In the United States, two schools of thought concerning the latitude that should be granted investment trust management have developed. One adheres to the British example and gives the management discretion, subject to the limiting clauses of the charter of the enterprise. The other virtually deprives management of all discretion after the initial selection of securities. In between, a compromise, semi-fixed type of trust has developed.

Most investment trusts take the legal form of corporations which are in a position to offer a variety of securities, including debentures and common and preferred stocks. The Second International Securities Corporation, which is of this type, discloses that it pays the American Founders Trust $\frac{1}{2}$ of 1% of the value of the corporation's average resources, for management. The International Securities Corporation of America, which is closely allied, makes an annual management charge of 4% of income, which in practice has worked out to about the same. The Mutual Investment Trust, another company, gives holders of its A shares, which are sold to the public, a preferential return of 6%. The management company subscribes 10% in cash against every new certificate sold to an outsider. After the outside investor has received 6%, the company gets 6% on its investment. Then the residue of income is divided equally between the outside investor and the management company.

Competent observers have pointed out that investment trusts are springing up faster than experienced managers are being trained. In some instances the new issues are sold on the basis of high pressure selling ability, rather than because of capacity of investment management. In 1928 several investment trusts were in liquidation, and it is possible that others may undergo a similar fate, or else a process of consolidation, before the pioneer period of experiment, adjustment and competition is over. In 1924 the governing committee of the New York stock exchange passed a resolution that participation by members of the exchange in the formation or management of investment trust corporations was an act held to be detrimental to the interests of the exchange. This resolution did much to prevent at the start abuses and unsound developments of the investment trust idea. The New York State law department has also conducted investigations to determine unsound practices and means of combating them. Since the investment trust has had long trial in England and is founded at bottom on sound principles, namely expert management and diversification, it is expected that it will certainly survive and continue to grow as long as prosperity continues. It is very necessary that prospective investors assure themselves that (a) the people managing the trust are possessed of character, foresight, integrity and responsibility, (b) that the managers have sufficient faith to risk a substantial amount of their own capital in the enterprise, (c) that books and accounts are properly kept with accurate and reasonably frequent reports to investors, (d) and that the companies are true investment trusts and are not merely masquerading under the name in order to secure clients.

Numerous American trusts have been sponsored by houses of issue. This connection raises the possibility that management will not be entirely disinterested. In such cases the trust could be used as a repository for the undigested new securities of the house of issue. An investor should carefully check the character and experience of the management through independent sources, and should examine the conditions of the association. He should seek to learn whether securities have been placed in the trust at cost or whether the managers act as principals and make a profit. Furthermore, he should become fully aware of the ratio of earnings on his capital which will be credited to him. To ascertain this information, he should find out the exact schedule for deductions which the organizers will make for themselves. He should also look into the policy in respect to reserves, and should ascertain the policy in regard to publicity.

See L. T. Grayson, *Investment Trusts* (1928); L. R. Robinson, *Investment Trust Organization and Management* (1926), and *Survey of Investment Trusts* (1926), and *Supplemental Survey* (1928), Securities Bureau of the New York State Law Department. (M. S. R.)

INVISIBLE EXPORTS: see EXPORTS, INVISIBLE.

INVOICE, a statement giving full particulars of goods sent or shipped by a trader to a customer, with the quantity, quality and prices, and the charges upon them (originally a plural, *Invoyes* or *Invoyes*, of *Invoy*, a variant of "envoy" from the French *envoyer*, to send). Consular invoices, i.e., invoices signed at the port of shipment by a consul of the country to which the goods are being consigned, are generally demanded by those countries which impose *ad valorem* duties.

INVOLUCRE. The whorl of bracts at the base of the inflorescences or general umbel in umbelliferous plants is called a *general involucre*; the similar leafy whorl adjoining the smaller umbels or umbellules being termed an *involcel* or *partial involucre*. In Compositae the name is applied to the bracts surrounding the head of the flower characteristic of this family and Umbelliferae. See FLOWER, UMBELLIFERAE and COMPOSITAE.

INVOLUTION, in arithmetic is the operation of raising a number to any power, rolling it up, as it were, by continued multiplication. Before the invention of a satisfactory symbol like a^2 or a^3 , the Greeks spoke of the second power as a "tetragon number" (*τετραγωνος αριθμος*, *tetrág' onos arithmos*, four-angled number) or a "power" (*δυναμις*, *dýnamis*, whence also "dynamo" and "dynamite"). Diophantus (c. 275) called the third power a cube (*κύβος*, *cu'bos*, see CUBE), the fourth power a "power-power" (*δυναμοδυναμις*, *dynamody'namis*), a fifth power a "power-cube" and so on, using the additive principle.

Involution is the converse of evolution (*q.v.*), which is the operation of finding a root. See ARITHMETIC. In geometry, an involution is a one-to-one correspondence between two ranges of points or between two pencils. See PROJECTIVE GEOMETRY. The "involute" of a curve is the locus of the end of a string when unwrapped from the curve itself.

IO, in Greek mythology, daughter of Inachus, the river-god of Argos and its first king. Under the name of Callithyia, Io was regarded as the first priestess of Hera. Zeus fell in love with her, and, to protect her from the wrath of Hera, changed her into a white heifer; according to Aeschylus (*Supplikes*, 299) the metamorphosis was the work of Hera herself. Hera, having persuaded Zeus to give her the heifer, set Argus Panoptes to watch her. Zeus thereupon sent Hermes, who lulled Argus to sleep and cut off his head or killed him with a stone. But the wrath of Hera still pursued Io. Maddened by a gadfly sent by the goddess, she wandered all over the earth (Aesch. *P.V.*, 561, et seq.), swam the strait known on this account as the Bosphorus (Ox-ford), and crossed the Ionian sea (traditionally called after her) until at last she reached Egypt, where she was restored to her original form and became the mother of Epaphus. She was thus identified with Isis, and Epaphus with Apis. He was said to have been carried off by order of Hera to Byblus in Syria, where he was found again by Io. This fable connects Io with the Syrian Astarte. Both legends reflect intercourse with the East and identification of foreign with Greek gods. She was a favourite subject among Greek painters, and many representations are preserved on vases and wall paintings.

IODINE, a chemical element, belonging to the halogen group, was discovered in 1812 by B. Courtois when investigating the products obtained from the mother-liquors prepared by lixiviating kelp or burnt seaweed. It forms heavy, blackish scales with a violet lustre which gives it a metallic appearance. In 1815 L. J. Gay-Lussac showed it was an element. Iodine (symbol I, atomic number 53, atomic weight 126.92) is not in nature uncombined; it is found very widely but sparingly distributed, chiefly in the form of its sodium and potassium salts. It is also found in small quantities in seawater, in some seaweeds, and in various mineral and medicinal springs. Deep-sea weeds, as a rule, contain more iodine than those which are found in the shallow waters.

Iodine is obtained either from kelp (the ashes of burnt seaweed) or from the mother-liquors obtained in the purification of Chile saltpetre. In the former case the seaweed is burnt in large heaps at as low a temperature as possible, and the product is known either as *kelp* or *varec*. Another method is to heat the seaweed in large retorts, whereby tarry and ammoniacal liquors pass over and a very porous residue of kelp remains. A later method consists in boiling the weed with sodium carbonate; the liquid is filtered and hydrochloric acid added to the filtrate, when *alginic acid* is precipitated; this is also filtered off, the filtrate neutralized by caustic soda, and the whole evaporated to dryness and carbonized, the residue obtained being known as *kelp substitute*. The kelp obtained by any of these methods is then lixiviated with water, which extracts the soluble salts, and the liquid is concentrated, when the less soluble salts, which are chiefly alkaline chlorides, sulphates and carbonates, crystallize out and are removed. Sulphuric acid is now added to the liquid, whereby alkaline sulphides and sulphites present are decomposed and iodides and bromides are converted into sulphates, while hydriodic and hydrobromic acids are liberated and remain dissolved in the solution. The liquid is run into the iodine still and gently warmed, manganese dioxide in small quantities being added from time to time, when the iodine distills over and is collected. In the second method it is found that the mother-liquors obtained from Chile saltpetre contain small quantities of sodium iodate, NaIO_3 ; this liquor is mixed with the calculated quantity of sodium bisulphite in large vats, and iodine is precipitated:—

The precipitate is washed and then distilled from iron retorts. Iodine may also be prepared by the decomposition of an iodide with chlorine, or by heating a mixture of an iodide and manganese dioxide with concentrated sulphuric acid. Commercial iodine may be purified by mixing it with a little potassium iodide and then subliming the mixture; in this way any traces of bromine or chlorine are removed.

Iodine's specific gravity is 4.948 ($17^\circ/4^\circ$), melting at 114.2°C ; it boils at 184.35°C under atmospheric pressure (W. Ramsay and S. Young). The specific heat of solid iodine is 0.0541 (H. Kopp). Its latent heat of fusion is 11.7 calories, and its latent heat of vaporization is 23.95 calories (P. A. Favre and J. T. Silbermann). It volatilizes slowly at ordinary temperatures, but rapidly on heating. Iodine vapour on heating passes from a violet colour to a deep indigo blue.

Iodine possesses a characteristic penetrating smell, not so pungent, however, as that of chlorine or bromine. It is only very sparingly soluble in water, but dissolves readily in solutions of the alkaline iodides and in alcohol, ether, carbon disulphide, chloroform and many liquid hydrocarbons. Its solutions in the alkaline iodides and in alcohol and ether are brown in colour, whilst in chloroform and carbon disulphide the solution is violet, and in the latter cases there is some indication of combination with the solvent. Its chemical properties resemble those of chlorine and bromine; its affinity for most other elements, however, is less than theirs. It will only combine with hydrogen in the presence of a catalyst, but combines with many other elements directly; for example, phosphorus melts and then inflames, antimony burns in the vapour, and mercury when heated with iodine combines with it rapidly. It is completely oxidized to iodic acid when boiled with fuming nitric acid. It is soluble in a solution of caustic potash, a dilute solution most probably containing the hypoiodite, which changes slowly into a mixture of iodide and iodate; change is rapid on warming. Iodine is readily detected by the characteristic blue coloration that it immediately gives with starch paste in the presence of soluble iodides; the colour is destroyed on heating, but returns on cooling provided the heating has not been too prolonged. Iodine in the presence of water frequently acts as an oxidizing agent; thus arsenious acid and the arsenites, on the addition of iodine solution, are converted into arsenic acid and arsenates.

Iodine finds application in organic chemistry, forming additional

products with unsaturated compounds, the combination, however, being more slow than in the case of chlorine or bromine. It rarely substitutes directly, because the hydriodic acid produced reverses the reaction; this can be avoided by the presence of precipitated mercuric oxide or iodic acid, which react with the hydriodic acid as fast as it is formed, and consequently remove it from the reacting system. As a rule it is preferable to use iodine in the presence of a carrier, such as amorphous phosphorus or ferrous iodide or to use it with a solvent. It is found that most organic compounds containing the grouping $\text{CH}_3\text{CO}\cdot\text{C}$ — or $\text{CH}_3\text{CH}(\text{OH})\cdot\text{C}$ — in the presence of iodine and alkali give iodoform, CHI_3 (*q.v.*).

Hydriodic Acid, HI, is formed by passing hydrogen and iodine vapour through a hot tube, but the reaction is reversible, $\text{H}_2 + \text{I}_2 \rightleftharpoons 2\text{HI}$. On shaking iodine with a solution of sulphuretted hydrogen in water, a solution of hydriodic acid is obtained, sulphur being at the same time precipitated. The acid cannot be prepared by the action of concentrated sulphuric acid on an iodide on account of secondary reactions taking place, which result in the formation of free iodine and sulphur dioxide. The usual method is to make a mixture of amorphous phosphorus and a large excess of iodine and then to allow water to drop slowly upon it; the reaction starts readily, and the gas obtained can be freed from any admixed iodine vapour by passing it through a tube containing some amorphous phosphorus. It is a colourless sharp-smelling gas which fumes strongly on exposure to air. It readily liquefies at 0°C under a pressure of four atmospheres, the liquefied acid boiling at -34.14°C (730.4 mm.); it can also be obtained as a solid melting at -50.8°C . It is readily soluble in water, one volume of water at 10°C dissolving 425 volumes of the gas. The saturated aqueous solution is colourless and fumes strongly on exposure to air; after a time it darkens in colour owing to liberation of iodine. When boiled the solutions lose either acid or water until a solution containing 58% of HI is obtained, which distills unchanged at 127°C . This has a specific gravity of 1.7 and is used in the Zeisel method of determining methoxyl groups. The gas is readily decomposed by heat into its constituent elements. It is a powerful reducing agent, and is frequently employed for this purpose in organic chemistry; thus hydroxy-acids are readily reduced on heating with the concentrated acid, and nitro-compounds are reduced to amino-compounds, etc. It is preferable to use the acid in the presence of amorphous phosphorus, for the iodine liberated during the reduction is then utilized in forming more hydriodic acid, and consequently the original amount of acid goes much further. It forms addition compounds with unsaturated compounds.

It has all the characteristics of an acid, dissolving many metals with evolution of hydrogen and formation of salts, called *iodides*. The iodides can be prepared either by direct union of iodine with a metal, from hydriodic acid and a metal, oxide, hydroxide or carbonate, or by action of iodine on some metallic hydroxides or carbonates (such as those of potassium, sodium, barium, etc.; other products, however, are formed at the same time). The iodides as a class resemble the chlorides and bromides, but are less fusible and volatile. Silver, mercurous, mercuric and cuprous iodides are insoluble in water; lead iodide is sparingly soluble, whilst most of the other metallic iodides are soluble. Cupric iodide is unstable and breaks down to cuprous iodide and iodine. Strong heating decomposes the majority of the iodides. Nitrous acid and chlorine readily decompose them with liberation of iodine; the same effect is produced when they are heated with concentrated sulphuric acid and manganese dioxide. The soluble iodides, on the addition of silver nitrate to their nitric acid solution, give a yellow precipitate of silver iodide, which is insoluble in ammonia solution. Hydriodic acid and the iodides may be estimated by conversion into silver iodide.

Iodine combines with chlorine to form *iodine monochloride*, ICl , which may be obtained by passing dry chlorine over dry iodine until the iodine is completely liquefied. It is readily decomposed by water. The *trichloride*, ICl_3 , results from the action of excess of chlorine on iodine, or from iodic acid and hydrochloric acid, or by heating iodine pentoxide with phosphorus

pentachloride. It crystallizes in long yellow needles and decomposes readily when heated into the monochloride and chlorine. It is readily soluble in water, but excess of water decomposes it. Iodine monochloride in glacial acetic acid solution is used for obtaining the "iodine value" of fats and oils in the Wijs method.

Iodine pentoxide, I_2O_5 , the best known oxide, is obtained as a white crystalline solid when iodic acid is heated to 170°C ; it is easily soluble in water, combining to regenerate iodic acid; and when heated to 300°C it breaks up into its constituent elements. It is used in the detection of carbon monoxide (see CARBON), which it oxidizes with liberation of iodine: $I_2O_5 + 5CO = I_2 + 5CO_2$. *Iodine dioxide*, IO_2 or I_2O_4 , is a lemon-yellow solid obtained by acting on iodic acid with sulphuric acid, or by grinding iodine with cold fuming nitric acid.

Although *hypoiodous acid* is not known, it is extremely probable that on adding iodine or iodine monochloride to a dilute solution of a caustic alkali, hypoiodites are formed, the solution obtained having a characteristic smell of iodoform, and being of a pale yellow colour. It oxidizes arsenites, sulphites and thiosulphates immediately. The solution is readily decomposed on the addition of sodium or potassium bicarbonates with liberation of iodine. The hypoiodite disappears gradually on standing, and rapidly on warming, being converted into a mixture of iodide and iodate.

Iodic Acid, HIO_3 , can be prepared by dissolving iodine pentoxide in water; by boiling iodine with fuming nitric acid, $6I + 10HNO_3 = 6HIO_3 + 10NO + 2H_2O$; by decomposing barium iodate with the calculated quantity of sulphuric acid, previously diluted with water; or by suspending iodine in water and passing in chlorine, $I_2 + 5Cl_2 + 6H_2O = 2HIO_3 + 10HCl$. It is a white crystalline solid, dissolving readily in water to give an acidic solution. It is a most powerful oxidizing agent, readily changing phosphorus to phosphoric acid, arsenic to arsenic acid, silicon at 250°C to silica, and hydrochloric acid to chlorine and water. It is readily reduced, with separation of iodine, by sulphur dioxide, hydriodic acid or sulphuretted hydrogen, thus:—

The salts, known as the *iodates*, can be prepared by the action of the acid on a base, or sometimes by the oxidation of iodine in the presence of a base. They are mostly insoluble or only very slightly soluble in water. The iodates of the alkali metals are, however, readily soluble in water (except potassium iodate). They are decomposed on heating, with liberation of oxygen, in some cases leaving a residue of iodide and in others a residue of oxide of the metal, with liberation of iodine as well as of oxygen. It is noteworthy that, although chlorine or bromine will displace iodine from an iodide, yet in these highly oxygenated acids the reverse obtains and iodine displaces chlorine (see the preparation of periodic acid).

Periodic acid, $HIO_4 \cdot 2H_2O$, is only known in the hydrated form. It can be prepared by the action of iodine on perchloric acid, or by boiling normal silver periodate with water: $2AgIO_4 + 4H_2O = Ag_2H_3IO_6 + HIO_4 \cdot 2H_2O$. It is a colourless, crystalline, deliquescent solid which melts at 135°C , and at 140°C is completely decomposed into iodine pentoxide, water and oxygen. A remarkable feature of iodic and periodic acids is the ease with which they give complex salts, e.g., $KH(IO_3)_2$, $KH_2(IO_3)_3$, K_5IO_6 (compare $HIO_4 \cdot 2H_2O$), etc.

Iodine has extensive applications in volumetric analysis, being used more especially for the determination of copper in virtue of the reaction: $2CuSO_4 + 4KI = 2K_2SO_4 + Cu_2I_2 + I_2$.

In *medicine* iodine is frequently applied externally as a counter-irritant, having powerful antiseptic properties. In the form of certain salts iodine is very widely used, for internal administration in medicine and in the treatment of many conditions usually classed as surgical, such as the bone manifestations of tertiary syphilis. The most commonly used salt is the iodide of potassium; the iodides of sodium and ammonium are almost as frequently employed, and those of calcium and strontium are in occasional use. The usual doses of these salts are from five to thirty grains or more. Their pharmacological action is as obscure as their

effects in certain diseased conditions are consistently brilliant and unexampled. Our ignorance of their mode of action is cloaked by the term *deobstruent*, which implies that they possess the power of driving out impurities from the blood and tissues. Most notably is this the case with the poisonous products of syphilis. In its tertiary stages—and also earlier—this disease yields in the most rapid and unmistakable fashion to iodides; so much so that the administration of these salts is at present the best means of determining whether, for instance, a cranial tumour be syphilitic or not. No surgeon would think of operating on such a case until iodides had been freely administered and, by failing to cure, had proved the disease to be non-syphilitic. Another instance of this deobstruent power—"alterative," it was formerly termed—is seen in the case of chronic lead poisoning. The essential part of the medicinal treatment of this condition is the administration of iodides, which are able to decompose the insoluble albuminates of lead, which have become locked up in the tissues, rapidly causing their degeneration, and to cause the excretion of the poisonous metal by means of the intestine and the kidneys. The following is a list of the principal conditions in which iodides are recognized to be of definite value: metallic poisonings, as by lead and mercury, asthma, aneurism, arteriosclerosis, angina pectoris, gout, goitre, syphilis, haemophilia, Bright's disease (nephritis) and bronchitis.

A minute proportion of iodine in the diet appears to be essential for health. This was formerly supplied as an accidental impurity in table salt, but the highly purified article now used as a condiment is free from iodides, and in certain States (e.g., some cantons of Switzerland) iodides are added to the drinking water. The deficiency is of greater significance in the case of small children, for the iodine is required for the synthesis of thyroxine, the active principle of the thyroid gland, which, however, has been artificially prepared by C. R. Harington and G. Barger (*Biochem. J.*, 1927, 21, p. 169).

IODINE-BUSH (*Allenrolfea occidentalis*), a North American plant of the goosefoot family (Chenopodiaceae), native to moist alkaline clay soil from western Texas to central California. It is an erect, diffusely branched shrub, 2 ft. to 5 ft. high, with alternate, fleshy, green, apparently leafless, jointed branches, the leaves being reduced to minute pointed scales or wanting. The numerous small flowers are arranged spirally by threes in crowded cylindrical spikes, $\frac{1}{4}$ in. to $\frac{3}{4}$ in. long, borne in the axils of fleshy bracts near the ends of the branches. In appearance the plant is suggestive of a tall, much-branched form of the glass-wort (*q.v.*) or samphire, to which it is closely allied.

IODINE VALUE, of an oil or fat, is the percentage of iodine it absorbs when dissolved in chloroform or carbon tetrachloride and treated with iodine chloride. This furnishes one of the most important methods of identifying an oil or fat; it gives a measure of the unsaturated fatty acids (*q.v.*) present, which gives a basis for the classification of oils, fats and waxes (*q.v.*).

IODOFORM, a valuable antiseptic discovered by G. S. Sérullas in 1822. Iodoform, CHI_3 , is formed by the action of iodine and aqueous potassium hydroxide on ethyl alcohol, acetone, acetaldehyde, isopropyl alcohol and most compounds containing the group $CH_3 \cdot CO \cdot C$. It crystallizes in yellow hexagonal plates, melting at 119 – 120°C , and is readily soluble in alcohol or ether, but insoluble in water. It has a characteristic odour and is volatile in steam. On reduction with hydriodic acid, it yields methylene iodide, CH_2I_2 .

Iodoform is also prepared by electrolysis of a solution of potassium iodide in the presence of alcohol or acetone. A solution of potassium iodide and sodium carbonate in water with the necessary alcohol is contained in a porous cell fitted with a lead anode, whilst the cathode compartment contains a solution of caustic soda and a nickel electrode. The electrolysis is carried out at a temperature of 70°C , with a current density of one ampère per square decimetre. After three hours the yield is 70% of the calculated quantity.

From its formula it can be seen to be strictly analogous with chloroform, $CHCl_3$, which is trichloromethane, while iodoform is

tri-iodomethane.

IOLA, city, south-eastern Kansas, U.S.A., on the Neosho river; the county seat of Allen county. It is on Federal highways 54 and 73W, and is served by the Missouri-Kansas-Texas, the Missouri Pacific and the Santa Fe railways. The population in 1925 was 7,990. It is the trade centre of one of the leading dairy districts of the State. Its industries include a milk condensery with a capacity of 150,000 lb. daily, large creameries, a cement plant, iron works and a pearl-button factory. Iola was founded in 1859, by a company that was dissatisfied with the location of the county seat at Humboldt. It became the county seat in 1865, and was chartered as a city in 1870. Natural gas was discovered here on Christmas Day, 1893, and a period of rapid development followed. The city has a commission form of government.

IOHITE: see **CORDIERITE**.

ION, of Chios, Greek poet, lived in the age of Pericles. At an early age he went to Athens, where he made the acquaintance of Aeschylus. He was an admirer of Cimon and an opponent of Pericles. Later he met Sophocles in Chios at the time of the Samian war. Aristophanes' *Peace*, 830 ff., seems to show that he died before 421. His first tragedy was produced between 452-449 B.C.; and in 429 he was third to Euripides and Iophon. In a subsequent year when he gained both the tragic and dithyrambic prizes, he gave a jar of Chian wine to every Athenian citizen (Athanaeus p. 3). According to the scholiast on Aristophanes (*loc. cit.*) he composed comedies, dithyrambs, epigrams, paeans, hymns, scolia, encomia and elegies. He also wrote an account of the antiquities of Chios and ἐπιδημῖαι, recollections of visitors to the island.

See C. Nieberding, *De Ionis Chii vita* (1836, containing the fragments); F. Allègre, *De Ione Chio* (1890), an exhaustive monograph; and Bentley, *Epistola ad Millium*.

IONA or **ICOLMKILL**, island, Inner Hebrides, Argyllshire, Scotland, $6\frac{1}{2}$ m. S. of Staffa and $1\frac{1}{4}$ m. W. of the Ross of Mull, from which it is separated by the shallow Sound of Iona. Pop. (1921) 234. It is about $3\frac{1}{2}$ m. long and $1\frac{1}{2}$ m. broad; its area being some 2,200 acres, of which about one-third is under cultivation, oats, potatoes and barley being grown. In the rest of the island grassy hollows, yielding pasturage for a few hundred cattle and sheep and some horses, alternate with rocky elevations, which culminate on the northern coast in Duni (332 ft.), from the base of which a stretch of white shell sand, partly covered with grass, stretches to the sea. To the south-west the island is fringed with precipitous cliffs. There is a ferry to the Ross of Mull. The inhabitants depend partly on agriculture and partly on fishing. Near the S.E. point is a marble quarry.

The original form of the name Iona was Hy, Hii or I, the Irish for Island. By Adamnan in his *Life* of St. Columba it is called *Ioua insula*, and the present name Iona is said to have originated in some transcriber mistaking the *u* in Ioua for *n*. It also received the name of Hii-colum-kill (Icolmkill), that is, "the island of Columba of the Cell," while by the Highlanders it has been known as Innis nan Druidhneah ("the island of the Druids"). This last name seems to imply that Iona was a sacred spot before St. Columba landed there in 563 and laid the foundations of his monastery. After this date it developed into the most famous centre of Celtic Christianity, the mother community of numerous monastic houses, whence missionaries were despatched for the conversion of Scotland and northern England, and to which for centuries students flocked from all parts of the north. After St. Columba's death his relics rested here until they were removed to Ireland early in the 9th century. Pilgrims came to die in the island, in order that they might lie in its holy ground; and from all parts of northern Europe the bodies of the illustrious dead were brought here for burial. Several times the monastery was plundered and burnt and the monks massacred by the heathen Norse sea-rovers, attracted by the wealth of the foundation. Late in the 11th century the desecrated monastery was restored by Queen Margaret, wife of Malcolm Canmore, king of Scotland; and in 1203 a new monastery and a nunnery were founded by Benedictine monks who either expelled or absorbed the Celtic community. In 838 the Western Isles, then under the rule of

the kings of Man, were erected into a bishopric of which Iona was the seat. When in 1098 Magnus III., "Barefoot," king of Norway, ousted the jarls of Orkney from the isles, he united the see of the Isles (Sudreyar, "the southern islands," Lat. *Sodorenses insulae*) with that of Man, and placed both under the jurisdiction of the archbishopric of Trondhjem. About 1507 the island again became the seat of the bishopric of the Isles; but with the victory of the Protestant party in Scotland its ancient religious glory was finally eclipsed, and in 1561 the monastic buildings were dismantled by order of the Convention of Estates. (For the political fortunes of Iona see **HEBRIDES**.)

The cathedral church of St. Mary dates from the 13th century; a great portion of the walls with the tower are still standing. The choir and nave have been roofed, and the cathedral has in other respects been restored, the ruins having been conveyed in 1899 to a body of trustees by the eighth duke of Argyll. The remains of the conventual buildings still extant, to judge by the portion of a Norman arcade, are of earlier date than the cathedral. The small chapel of St. Oran, or Odhrain, the oldest building on Iona, which was built by Queen Margaret on the supposed site of Columba's cell, was in process of restoration in 1927. Of the nunnery only the chancel and nave of the Norman chapel remain, the last prioress, Anna (d. 1543), being buried within its walls. The cemetery, called in Gaelic *Reilig Oiran* ("the burial-place of kings"), is said to contain the remains of forty-eight Scottish, four Irish and eight Danish and Norwegian monarchs, but most of the monumental stones were thrown into the sea at the time of the Reformation. Those that remain have been restored and enclosed. The finest, those of Maclean and St. Martin, are still almost perfect, and are richly carved.

IONIA, in ancient geography, the name given to a portion of the west coast of Asia Minor, adjoining the Aegean Sea and bounded on the east by Lydia. It consisted of a narrow strip of land near the coast, which together with the adjacent islands was occupied by immigrant Greeks (Ionians), and thus distinguished from the interior district, inhabited by the Lydians. According to the universal Greek tradition, the cities of Ionia were founded by emigrants from the other side of the Aegean (see **IONIANS**), and their settlement was connected with the legendary history of the Ionians in Attica, for the colonists were led by Neleus and Androclus, sons of Codrus, the last king of Athens. Modern thought tends to support the popular Greek idea that Ionia received its main Greek element rather late—after the descent of the Dorians, and, therefore, after the Aegean period. Herodotus tells us (i. 146) that the colonists comprised settlers from many different tribes and cities of Greece (a fact indicated also by the local traditions of the cities), and that they intermarried with the native people.

The cities called Ionian in historical times were twelve in number—an arrangement copied as it was supposed from the constitution of the Ionian cities in Greece which had originally occupied the territory in the north of the Peloponnese subsequently held by the Achaeans. These were (from south to north)—Miletus, Myus, Priene, Ephesus, Colophon, Lebedus, Teos, Erythrae, Clazomenae and Phocaea, together with Samos and Chios. Smyrna (*q.v.*), originally an Aeolic colony, was afterwards occupied by Ionians from Colophon, and became an Ionian city—an event which had taken place before the time of Herodotus. But at what period it was admitted as a member of the league is not known. Like the Amphictyonic league in Greece, the Ionic was rather of a sacred than a political character; every city enjoyed absolute autonomy, and, though common interests often united them for a common political object, they never formed a real confederacy like that of the Achaeans or Boeotians.

Ionia was a mountainous country, 90 m. long from north to south, with a breadth varying from 20 to 30 m.; to this area must be added that of the peninsula of Mimas, together with that of two large islands. Among the outstanding peaks were Mimas and Corycus, situated on the peninsula which stands out to the west, facing the island of Chios; Sipylus, to the north of Smyrna; Corax, extending to the south-west from the Gulf of Smyrna, and descending to the sea between Lebedus and Teos.

The strongly marked range of Mycale, a continuation of Messogis in the interior, forms the bold headland of Trogilium or Mycale, opposite Samos. None of these mountains attains a height of more than 4,000 feet. The district comprised three extremely fertile valleys; the Hermus in the north, flowing into the Gulf of Smyrna; the Cayster, which flowed under the walls of Ephesus; and the Maeander, which in ancient times discharged its waters into the deep gulf that once came up to the walls of Miletus, but which has been gradually silted up by deposits brought down by the river. In ancient times Ionia was considered the most fertile of all the provinces of Asia Minor. It still produces an abundance of fruit of all kinds.

The colonies naturally became prosperous. Miletus especially was at an early period one of the most important commercial cities of Greece; and in its turn became the parent of numerous other colonies, which extended all around the shores of the Euxine and the Propontis from Abydos and Cyzicus to Trapezus and Panticapaeum. The mariners of Phocaea extended their influence to the shores of the western Mediterranean. Ephesus, though it did not send out any colonies of importance, from an early period became a flourishing city.

History.—About the middle of the 7th century B.C., the Cimmerii (see SCYTHIA) ravaged a great part of Asia Minor, including Lydia, and sacked Magnesia on the Maeander, but failed to take Ephesus. About 700 B.C. Gyges, first Mermnad king of Lydia, invaded the territories of Smyrna and Miletus, and is said to have taken Colophon as his son Ardys did Priene. But it was not till the reign of Croesus (560–545 B.C.) that the cities of Ionia successively fell under Lydian rule. The defeat of Croesus by Cyrus was followed by the conquest of all the Ionian cities. They became subject to the Persian monarchy with the other Greek cities of Asia. They continued to enjoy a considerable amount of autonomy, but were subject to local despots. It was at the instigation of one of these, Histiaeus (q.v.) of Miletus, that in about 500 B.C. the principal cities broke out into insurrection against Persia. They were at first assisted by the Athenians, with whose aid they penetrated into the interior and burnt Sardis, an event which ultimately led to the Persian invasion of Greece. But the Ionian fleet was defeated off the island of Lade, and the destruction of Miletus after a protracted siege was followed by the reconquest of all the Asiatic Greeks.

The Greek victories during the Persian war had the effect of enfranchizing their kinsmen on the other side of the Aegean; and the battle of Mycale (479 B.C.), in which the defeat of the Persians was in great measure due to the Ionians, secured their emancipation. They henceforth became the dependent allies of Athens (see DELIAN LEAGUE), though still retaining their autonomy, which they preserved until the peace of Antalcidas in 387 B.C. once more placed them as well as the other Greek cities in Asia under the nominal dominion of Persia. They appear, however, to have retained a considerable amount of freedom until the invasion of Asia Minor by Alexander the Great. After the battle of the Granicus most of the Ionian cities submitted to the conqueror. Miletus, which alone held out, was reduced after a long siege (334 B.C.). From this time they passed under the dominion of the successive Macedonian rulers of Asia, but continued, with the exception of Miletus (q.v.), to prosper both under these Greek dynasties and after they became part of the Roman province of Asia.

Ionia was the home of the Ionian School of Philosophy (q.v.) and it led the way also for the brilliant artistic development of Athens in the 5th century. Ionian art flourished in the 8th, 7th and 6th centuries, and is distinguished by the fineness of workmanship and minuteness of detail with which it treated subjects, inspired to some extent by non-Greek models. (See GREEK ART.)

See D. G. Hogarth, *Ionia and the East* (1909).

IONIA, city, Michigan, U.S.A., on the Grand river, 34m. E. of Grand Rapids; the county seat of Ionia county. It is served by the Grand Trunk and the Pere Marquette railways. The population was 6,935 in 1920 (89% native white) and was estimated locally at 10,000 in 1928. Behind the city is an irregular semicircle of hills commanding extensive views of the valley. Ionia is

the trade centre of a rich farming district, and the seat of the State reformatory and a State hospital for the insane. The Pere Marquette maintains repair-shops, and the manufactures include automobiles, reed chairs, florists' pots, porcelain tiles, wire and furniture. Ionia was settled in 1833 by colonists from German Flats, near Herkimer, New York. It was incorporated as a village in 1857, and was chartered as a city in 1873.

IONIAN ISLANDS, the collective name for the Greek islands of Corfu, Cephalonia, Zante, Santa Maura, Ithaca, Cythera (Cerigo) and Paxo (q.v.), with their minor dependencies. These islands, though often described as the *Heptanesus* ("Seven Islands"), have no geographical unity. The name "Ionian" is obscure, but is probably due to ancient Ionian colonies, for example in Corfu from Eretria. The political unity of the islands is comparatively modern; their independence as a separate state lasted only seven years (1800–7).

The Ionian islands consist almost entirely of Cretaceous and Tertiary beds, but in Corfu Jurassic deposits have been found. The oldest beds which have yet been recognized are shales and hornstones with Liassic fossils. These are overlaid conformably by a thick series of platy Viglās limestone, representing the rest of the Jurassic and the lower Cretaceous. Then follow dolomites and unbedded *Hippurites* limestones evidently Upper Cretaceous age. The Eocene beds are folded with the Cretaceous. Both occasionally assume the form of Flysch. Miocene beds are found in Corfu and Zante, and Pliocene deposits cover much of the low ground. (X.)

HISTORY

Mediaeval and Venetian Periods.—The beginning of Heptanesian history dates from the 9th century. Leo the Philosopher (c. A.D. 890) formed all or most of the islands into a distinct province of the Eastern empire under the title of the Thema of Cephallenia. Robert Guiscard captured Corfu (1081) and Cephalonia, but his early death prevented the establishment of a Norman dynasty. When the Latin empire was established at Constantinople in 1204 the Venetians received Corfu. After defeating the Genoese corsair Leon Vetrano, the senate granted fiefs in Corfu to ten noble families in order that they might colonise it (1206). The Greek "Despot" of Epeiros, however, captured the first Venetian colony in 1214, and a long period of Epirote, Sicilian and Neapolitan-Angevin rule followed till in 1386 the people of Corfu made voluntary submission to the Venetian republic.

Paxo, created a barony, was treated as part of Corfu. The County Palatine of Cephalonia (with Zante), seized by Matteo Orsini in 1194, owned the suzerainty first of Venice, then of Achaia, to which it was annexed in 1324. In 1357 it was bestowed upon the Tocco family of Benevento, and was united with Santa Maura and Ithaca (called Val di Conspre) in the Duchy of Leucadia. In 1479 the Turks annexed these four islands. But they gradually became Venetian; Cephalonia and Ithaca 1483–85, and from 1500 onwards; Zante 1482 and from 1485, and Santa Maura 1502–03 and from 1684. Cerigo, a Venetian Marquisate of the Venier family from 1207, became a Venetian colony in 1363, but was parcelled out between Venice and the Venier in 1393.

The Venetians, who exacted heavy contributions from the islands, won the adherence of the principal native families by the bestowal of titles and appointments; the Roman Catholic Church was established, and the Italian and Greek races were largely assimilated by intermarriage; Greek ceased to be spoken except by the lower classes, which remained faithful to the orthodox communion. On the fall of the Venetian republic in 1797 the Treaty of Campo Formio annexed the Ionian islands to France; but a Russo-Turkish force drove out the French at the close of 1798; and in the spring of 1799 Corfu capitulated. By treaty with the Porte in 1800, the Emperor Paul erected the "Septinsular Republic," but the Treaty of Tilsit (1807) declared the islands an integral part of the French empire. They were incorporated with the province of Illyria (q.v.); but British forces under General Oswald took Zante, Cephalonia and Cerigo in 1809, and Santa Maura in 1810; Colonel (afterwards Sir Richard) Church

(q.v.), reduced Paxo in 1814; and after the abdication of Napoleon, Corfu, which had been defended by General Donzelot, was, by order of Louis XVIII. surrendered to Sir James Campbell. By the Treaty of Paris (Nov. 9, 1815) the contracting powers (Great Britain, Russia, Austria and Prussia) agreed to place the "United States of the Ionian Islands" under the exclusive protection of Great Britain.

British Protectorate.—The constitutions, voted by a constituent assembly in 1817 and applied in the following year, placed the administration in the hands of a senate of six members and a legislative assembly of 40 members; but the real authority was vested in the high commissioner, Sir Thomas Maitland ("King Tom") (1815). The successive British commissioners, General Sir Frederick Adam (1823), Lord Nugent (1832) and Sir Howard Douglas (1835-41) did much for the administration, justice, education and communications of the islands, but their firm, often despotic rule was resented by the natives, the principal exponent of the opposition being the historian Andreas Mustoxidi (d. 1861). A complete change of policy was inaugurated by Mr. Mackenzie (1841-43), and Lord Seaton (1843-49) was induced by the European disturbances of 1848 to initiate a number of important reforms. But the party in favour of union with Greece was rapidly growing. Serious insurrections of the peasantry, especially in Cephalonia, had to be put down by military force, and the parliament passed a resolution in favour of immediate union with Greece.

Cession to Greece.—Contrary to the expectations of the Greeks, Mr. Gladstone, who toured the islands as high commissioner extraordinary, did not propose the abolition of the protectorate, and his successor, Sir Henry Storks, seemed indifferent or blind to the popular feeling, but on the abdication of King Otho of Greece in 1862 the British Government declared to the provisional government of Greece that the selection of Prince William George of Glücksberg would be followed by the cession of the Ionian islands. After the prince's election by the national assembly in 1863 the high commissioner laid before the Ionian Parliament the conditions of the cession. The rejection of one condition (the demolition of the fortifications of Corfu) led to a new prorogation, but on March 29, 1864, the plenipotentiaries of the five great Powers signed the treaty by which the protectorate was ended. Neutrality was confined to Corfu and Paxo. On May 3, 1864 Sir Henry Storks left Corfu with the British troops and men-of-war. King George made his entry into Corfu on June 6.

Since their annexation to Greece the history of the Ionian islands has been uneventful; their prosperity has somewhat declined. Corfu with Paxo; Cephalonia; Santa Maura (Levkas) with Ithaca and Zante (Zacynthos) each form separate monarchies or departments; Cerigo (Cýthera) forms part of the monarchy of Laconia. The islands retain the exemption from direct taxation which they enjoyed under the British protectorate; in lieu of this there is an *ad valorem* tax of 20½% on exported oil and a tax of 6% on wine exported to Greek ports; these commodities are further liable to an export duty of 1½% which is levied on all agricultural produce and articles of local manufacture for the maintenance and construction of roads.

IONIAN MODE: see HARMONY and PLAINSONG.

IONIANS. This name was used in classical times for one of the four divisions of the Greek world, the remaining three being Aeolic, Doric and Arcado-Cypriote or Achæan. This is strictly a linguistic division, and the Greeks did not recognize it in an exact sense. Aeolian, Dorian and Ionian were well-marked divisions socially as well as linguistically. There was also a strong race antipathy between Dorian and Ionian, manifested particularly in the Peloponnesian War, in which Athens and Sparta were the protagonists. Each was inclined to regard the other as not fully Hellenic. The Ionians claimed that the Dorians were the descendants of non-Greek northern invaders commingled with an earlier Greek population of the Peloponnese. The Dorians asserted that the Ionians were pre-Greek or Pelasgian, standing much in the same relationship to true Greeks as do the Welsh and other Britons to the Anglo-Saxons.

Attica was the centre of Ionic culture on the mainland. Euboea and the Cyclades were also regarded as Ionic with the exception of the Dorian islands of Melos and Thera, but the name Ionia itself in classical times was confined to the tract of land on the coast of Asia Minor that contained the Ionic cities. This lay between Aeolis on the north and Doris on the south, and extended from Smyrna to Miletus. The twelve cities, while retaining their independence in true Greek fashion, formed a league for social and religious purposes, their central cult being that of Poseidon carried on upon Mt. Mycale. The Ionians claimed that this worship derived from Achaia in the Peloponnese, but it at least contained elements that were Anatolian in origin. The Ionian cities were energetic, thriving and opulent. Their wealth made them luxurious and they had a name for effeminacy. They were subdued by Croesus, king of Lydia, in the middle of the sixth century and passed at his subjugation under the Persian empire. In 500 they revolted but were conquered by King Darius and a higher tribute was imposed upon them. After the successful termination of the Persian wars they were set free by the Greeks of the mainland under the leadership of Athens, but later fell again under Persia when that empire recovered its strength. They remained nominally subject to Persia till its overthrow by Alexander the Great. There were various Ionic colonies on the coast of the Euxine and in Sicily and Magna Graecia.

The chief characteristics of the Ionic dialect to which Attic was closely akin were: (i.) the representation of an original long *ā* by *ē*, for example in the word *μήτηρ* for Doric, etc., *μάτηρ*, Lat. *mater*; (ii.) the lengthening of the vowel before a nasal or liquid that preceded a lost digamma, e.g., *ξείνος*, *κούρη* for Attic *ξένος*, *κόρη*; (iii.) the nom. plur. of the personal pronouns in *-eis* instead of *-es*, e.g., *ἡμεῖς* for Doric *ἀμές*; (iv.) the termination *-ou* for pronominal adverbs of place (*ποῦ*, etc.) for West Greek *-ei*; the third person plural of certain aorist forms in *-σαν* (*ἔθεσαν*, *ἔδοσαν*) by analogy from an *s*-aorist; (v.) the very early loss of digamma, etc. Ionic-Attic with Aeolic formed loosely an eastern group of dialects as opposed to Doric and North-West Greek. The turning of the original dialect of the Homeric poems, Aeolic or otherwise, into Ionic where possible, i.e., where the exigencies of the metre, vocabulary, and other considerations permit, produced the artificial Epic dialect.

The name Ionians had probably a more extensive use in early times than in historical. In the Pentateuch, in the 15th or 16th century B.C. (Gen. x. 2), Javan appears as a son of Japheth. To the Hebrews the name represented the whole Greek race. To the Persians the Greeks were known as Yauna. It does not follow from this fact that the Greeks knew themselves by this name, for the case may be parallel to the Italians and Illyrians later applying to them the name of Graeci, that of the small Epirote tribe with whom they first came in contact. In view of the name of the

Ionian sea, which was ancient, it is possible that the mainland of Greece was once known as Ionia or its inhabitants as Ionians. No Ionian Greeks lived in historical times on the shores of the Ionian sea.

The Homeric Ionians were inhabitants of Attica (*Il.* xiii. 685). In the Hesiodic genealogies Ion was son of Xuthus and brother of Achaëus. According to Herodotus the original home of the Ionians was in north-east Peloponnese in the region around Troezen. Hence they were expelled by the Achaeans and occupied Attica, from which they later spread to the Cyclades and to Asia Minor. This traditional history of the Ionians is feasible and need not be dogmatically contradicted. We may perhaps regard the Ionians as pre-Achaean inhabitants of the Peloponnese disturbed by Achaean invaders from the eastern Aegean. This is the view of Kretschmer and of N. P. Nilsson, except that they bring the Achaeans as a second wave of Greek-speaking peoples from the north. Nilsson regards the Ionians as the foremost wave of Greek-speaking peoples to reach Greece and as the originators of the Mycenaean culture. Later came the Dorian invasion of the Peloponnese, consisting perhaps of two coincident elements, an irruption of Illyrian and Epirote tribes from the north-west and an invasion by sea from Crete. The Ionians when they emerge into history are a recognized integral part of the Greek world, distinguished like the Dorians by a well-marked dialect and a common cult. (See DORIANS; ACHAEANS: GREECE: History.)

IONIAN SCHOOL OF PHILOSOPHY. Under this name are included a number of philosophers of the 6th and 5th centuries B.C. Mainly Ionians by birth, they are united by a local tie and represent all that was best in the early Ionian intellect. It is a most interesting fact in the history of Greek thought that its birth took place not in Greece but in the colonies on the west coast of Asia Minor. But not only geographically do these philosophers form a school; they are one in method and aim. They all sought to explain the material universe as given in sensible perception; their explanation was in terms of matter, movement, force. In this they differed from the Eleatics and the Pythagoreans who thought in the abstract, and explained knowledge and existence in metaphysical terminology. In tracing the development of their ideas, two periods may be distinguished. The earliest thinkers down to Heraclitus endeavoured to find a material substance of which all things consist; Heraclitus, by his principle of universal flux, took a new line and explained everything in terms of force, movement, dynamic energy. The former asked the question, "What is the substratum of the things we see?"; the latter, "How did the sensible world become what it is; of what nature was the motive force?"

The first name in the list of the Ionian philosophers—and, indeed, in the history of European thought—is that of Thales (*q.v.*). He first, so far as we know, sought to go behind the infinite multiplicity of phenomena in the hope of finding an infinite unity from which all difference has been evolved. This unity he decided is Water. It is impossible to discover precisely what he conceived to be the relation of this unity to the plurality of phenomena. Later writers from whom we derive our knowledge of Thales attributed to him ideas which seem to have been conceived by subsequent thinkers. Thus the suggestion preserved by Stobaeus that he conceived water to be endowed with mind is discredited by the specific statement of Aristotle that the earlier physicists (*physiologi*) did not distinguish the material from the moving cause, and that before Anaxagoras no one postulated creative intelligence. Again in the *De anima* (i. 5) Aristotle quotes the statement that Thales attributed to water a divine intelligence, and criticizes it as an inference from later speculations. It is probably safest to credit Thales with the bare mechanical conception of a universal material cause, leaving pantheistic

ideas to a later period of thought.

The successors of Thales were Anaximander and Anaximenes, who also sought for a primal substance of things. Anaximander postulated a corporeal substance unlike any of the known substances. This substance he called "the Indeterminate" (*τὸ ἀπερον*). He felt that all determinate things have emerged from primal unity (first called *ἀρχή* by him) into which they must ultimately return. Change, growth and decay he explained on the principle of mechanical compensation.

Anaximenes, pupil of Anaximander, seems to have rebelled against the extreme materialism of his master. Perceiving that air is necessary to life, that the universe is surrounded by air, he was convinced that out of air all things have resulted. The process by which things grow is twofold, condensation (*πύκνωσις*) and rarefaction (*ἀραίωσις*), or, in other words, *heat* and *cold*. From the former process result cloud, water and stone; from the latter, fire and aether. This theory is closely allied to that of Thales, but it is superior in that it specifies the processes of change. Further, it is difficult not to accept Cicero's statement that Anaximenes made air a conscious deity; we are, at all events, justified in regarding Anaximenes as a link (perhaps an unconscious link) between crude Hylozoism (*q.v.*) and definitely metaphysical theories of existence.

We have seen that Thales recognized change, but attempted no explanation; that Anaximander spoke of change in two directions; that Anaximenes called these two directions by specific names. From this last, the transition to the doctrine of Heraclitus is easy. He felt that change is the essential fact of experience and pointed out that any merely physical explanation of plurality is inherently impossible. The Many is of Sense; Unity is of Thought. Being is intelligible only in terms of Becoming. That which is, is what it is in virtue of its perpetually changing relations (*πάντα ῥεῖ καὶ οὐδὲν μένει*). By this recognition of the necessary correlation of Being and Not-being, Heraclitus is in a very real sense the father of metaphysical and scientific speculation, and in him the Ionian school of philosophy reached its highest point. Yet there is reason to doubt the view of Hegel and Lassalle that Heraclitus recognized the fundamental distinction of subject and object and the relations of mind and matter. Like the early Ionians he postulated a primary substance, fire, out of which all things have emerged and into which all must return. This elemental fire is in itself a divine rational process, the harmony of which constitutes the law of the universe. Human knowledge consists in the comprehension of this all-pervading harmony as embodied in the manifold of perception; the senses are "bad witnesses" in that they report multiplicity as fixed and existent in itself rather than in its relation to the One. This theory gives birth to a sort of ethical by-product whose dominant note is Harmony, the subordination of the individual to the universal reason; moral failure is proportionate to the degree in which the individual declines to recognize his personal transience in relation to the eternal Unity. From the same principle there follows the doctrine of Immortality. The individual, like the phenomena of sense, comes out of the infinite and again is merged; hence on the one hand he is never a separate entity at all, while on the other hand he exists in the infinite and must continue to exist. Moreover, the soul approaches most nearly to perfection when it is least differentiated from elemental fire; it follows that "while we live our souls are dead within us, but when we die our souls are restored to life." This doctrine is at once the assertion and the denial of the self, and furnishes a striking parallel between European thought in its earliest stages and the fundamental principles of Buddhism. Knowledge of the self is one with knowledge of the Universal Logos (Reason); such knowledge is the basis not only of conduct but of existence itself in its only real sense.

Thus far the Ionian philosophers had held the field of thought. Each succeeding thinker had more or less assumed the methods of Thales, and had approached the problem of existence from the empirical side. About the time of Heraclitus, however, there sprang up a totally new philosophical spirit. Parmenides and Zeno (see ELEATIC SCHOOL) enunciated the principle that "Nothing is

born of nothing." Hence the problem becomes a dialectical a priori speculation wherein the laws of thought transcend the sense-given data of experience. It was therefore left for the later Ionians to frame an eclectic system, a synthesis of Being and Not-being, a correlation of universal mobility and absolute permanence. This examination of diametrically opposed tendencies resulted in several different theories. It will be sufficient here to deal with Anaxagoras, Diogenes of Apollonia, Archelaus and Hippo, leaving Empedocles, Leucippus and Democritus to special articles (*q.v.*). The latter three do not belong strictly to the Ionian School.

Anaxagoras (*q.v.*) elaborated a quasi-dualistic theory according to which all things have existed from the beginning. Originally they existed in infinitesimal fragments, infinite in number and devoid of arrangement. Amongst these fragments were the seeds of all things which have since emerged by the process of aggregation and segregation, wherein homogeneous fragments came together. These processes are the work of *Nous* (*νοῦς*) which governs and arranges. But this *Nous* or Mind, is not incorporeal; it is the thinnest of all things; its action on the particle is conceived materially. It originated a rotatory movement, which arising in one point gradually extended till the whole was in motion, which motion continues and will continue infinitely. By this motion things are gradually constructed not entirely of homogeneous particles (the homoeomerê, *ὁμοιομερῆ*) but in each thing with a majority of a certain kind of particle. It is this aggregation which we describe variously as birth, death, maturity, decay, and of which the senses give inaccurate reports. His vague dualism works a very distinct advance upon the crude hylozoism of the early Ionians (*see* *ΑΤΟΜ*), and the criticisms of Plato and Aristotle show how highly his work was esteemed. The great danger is that we should credit him with more than he actually thought. His *Nous* was not a spiritual force; it was no omnipotent deity; it is not a pantheistic world-soul. But by isolating Reason from all other growths, by representing it as the motor-energy of the Cosmos, in popularizing a term which suggested personality and will, Anaxagoras gave an impetus to ideas which were the basis of Aristotelian philosophy in Greece and in Europe at large.

In Diogenes of Apollonia we find a return to Anaximenes. Diogenes (*q.v.*) began by insisting on the necessity of there being only one principle of things, herein contradicting the pluralism of Heraclitus. This principle is that of the universal homogeneity of nature; all things are at bottom the same, or interaction would be impossible. This universal substance is Air. But Diogenes went much farther than Anaximenes by attributing to air not only infinity and eternity but also intelligence.

Another pupil of Anaxagoras was Archelaus of Miletus (*q.v.*). His work was mainly the combination of previous views, except that he is said to have introduced an ethical side into the Ionian philosophy. "Justice and injustice," he said, "are not natural but legal." He endeavoured to overcome the dualism of Anaxagoras, and in so doing approached more nearly to the older Ionians.

The last of the Ionians whom we need mention is Hippo (*q.v.*), who, like Archelaus, is intellectually amongst the earlier members of the school. He thought that the source of all things was moisture, and is by Aristotle coupled with Thales (*Metaphysics*, A 3).

IONIC ORDER, one of the classic orders (*q.v.*), usually listed as the second Greek or the third Roman. It is characterized especially by the capital whose most important feature is a horizontal band terminating at either end in large spiral scrolls or volutes.

IONIC THEORY: *see* **CHEMICAL ACTION** and **ELECTROLYSIS**.

IONIZATION POTENTIAL: *see* **RESONANCE POTENTIAL**.

IONS, CATALYTIC ACTION OF. The fact that many reactions are accelerated by acids and bases has been generally associated with the idea that the hydrogen and hydroxyl ions are unique in the possession of catalytic qualities. The term hydrogen ion is here understood to refer to the hydrated

form $\text{H}\cdot\text{H}_2\text{O}$ or oxonium ion OH_3^+ . In the case of acid catalysis, the simple hydrogen ion theory met for a long time with almost universal acceptance for the reason that it served to correlate with a fair degree of precision a large body of experimental facts. More recent studies, in which new reactions have been subjected to minute examination indicate, however, that there is in general no simple proportionality between the catalytic activity of an acid and either the concentration or the thermodynamic activity of the hydrogen ion. On the other hand, the observations show clearly that catalytic activity is by no means peculiar to the hydrogen and hydroxyl ions, but that similar qualities must be attributed to other positive and negative ions and also to electrically neutral molecules. The catalytic effects produced by a weak acid HA, when admixed with the corresponding salt for the purpose of reducing the preponderating influence of the hydrogen ion, require, indeed, for their representation an equation of the form

$$v = k_h[\text{OH}_3^+] + k_m[\text{HA}] + k_w[\text{H}_2\text{O}] + k_a[\text{A}^-] + k_{\text{OH}}[\text{OH}^-]$$

in which the total observed catalytic action is expressed as the sum of the joint effects due to the positive hydrogen ion, the neutral molecules HA and H_2O and the negative ions A^- and OH^- . The relative magnitudes of the individual catalytic effects depend on the nature of the reaction and also on the solvent medium. As might have been anticipated, the values of k_m , k_w , and k_a are usually very small compared with the values of k_h and k_{OH} .

If for a given reaction, the values of k_m and k_a for a series of different acids are compared, it is found that with increasing ionisation constant of the acid, the magnitude of k_m increases whilst that of k_a diminishes. The high efficiency of the hydroxyl ion as a catalytic agent is thus connected with the fact that water is an acid with a very small ionisation constant.

If certain secondary effects which depend on variations in the reaction medium are ignored, the results of recent work indicate that the catalytic effects which are produced by the positive and negative ions resulting from the dissociation of the acid HA may be expressed in terms of the hydrogen ion concentration in the form of a general relation which is independent of the nature of the acid and of its concentration. The relation in question,

which may be put in the form $r = \frac{1}{2}(n + \frac{1}{n})$ where r is a measure

of the catalytic effect of the ions, and n a measure of the hydrogen ion concentration, is also independent of the temperature, of the nature of the solvent medium and even of the nature of the catalysed reaction. The catalytic effects associated with the hydrogen and hydroxyl ions conform closely to the requirements of this generalisation.

As the result of catalytic observations, it is now recognised that the traditional conception of the relations between acids and bases is inadequate and requires modification. The modern view assigns to the free hydrogen ion or proton the rôle of the connecting link between the acids and bases as represented by the

formula: acid \rightleftharpoons base + H^+ . In accordance with this view OH_3^+ ,

NH_4^+ , HCl and $\text{CH}_3\text{CO}_2\text{H}$ are acids, and NH_3 , Cl^- , CH_3CO_2^- are bases. The water molecule affords an example of an amphoteric substance in that it may act as a proton donator (acid) or as a

proton acceptor (base) in accordance with $\text{H}_2\text{O} \rightarrow \text{H}^+ + \text{OH}^-$ and

$\text{OH}_3^+ \rightarrow \text{H}_2\text{O} + \text{H}^+$ respectively. (H. M. D.)

IOPHON, Greek tragic poet, son of Sophocles. He gained the second prize in 428 B.C., Euripides being first, and Ion third. In the *Frogs* of Aristophanes (405) he is spoken of as the only good Athenian tragic poet. He wrote 50 plays, of which only a few fragments remain. It is said that Iophon accused his father of being incapable of managing his affairs and that Sophocles was

triumphantly acquitted, on reading the famous chorus of the *Oedipus at Colonus* (688 ff.).

See Aristophanes, *Frogs*, 73, 78, with scholia; Cicero, *De senectute*, vii. 22; Plutarch, *Moralia*, 785, B; O. Wolff, *De Iophonie poeta* (Leipzig, 1884); A. Nauck, *Tragicorum Graecorum fragmenta* (1889).

IOTA, the ninth letter of the Greek alphabet corresponding to the ninth letter of the English alphabet. See I.

I.O.U. ("I owe you"), a written acknowledgment of a debt. It usually runs thus:

To——. I. O. U.——
(Signed)——. Date——.

An I.O.U., if worded as above, or even if the words "for value received" are added, needs no stamp in Britain, as it contains no term of agreement. If any such words as "to be paid on such a day" are added it requires a stamp. An I.O.U. should be addressed to the creditor by name, though its validity is not impaired by such omission. Being a distinct admission of a sum due, it is *prima facie* evidence of an account stated, but where it is the only item of evidence of account it may be rebutted by showing there was no debt and no demand which could be enforced by virtue of it. An I.O.U. is not negotiable in the technical sense. (See NEGOTIABLE INSTRUMENT.)

IOVILAE or **JOVILAE**, a latinized form of *iūvilas*, the name given by the Oscan-speaking Campanians in the 5th, 4th and 3rd centuries B.C. to an interesting class of monuments, not yet fully understood. They all bear crests or heraldic emblems proper to some family or group of families, and inscriptions directing the annual performance of certain ceremonies on fixed days. While some of them are dedicated to Jupiter (in a special capacity, which our present knowledge of Oscan is insufficient to determine), others were certainly found attached to graves.

See the articles *OSCA LINGUA*, *CAPUA*, *CUMAE* and *MESSAPII*. The text of all those yet discovered (at Capua and Cumae), with particulars of similar usages elsewhere in Italy and other historical and archaeological detail, is given by R. S. Conway in *The Italic Dialects* (Cambridge, 1897, pp. 101 ff.). (R. S. Co.)

IOWA (Īŏ-wā), known as the "Hawkeye State," is a north central State of the United States of America, situated between 40° 36' and 43° 30' N. and 89° 5' and 96° 31' W. It is bounded north by Minnesota, east by the Mississippi river, which separates it from Wisconsin and Illinois, south by Missouri, and west by the Missouri and Big Sioux rivers, which separate it from Nebraska and South Dakota. The State's total area is 56,147 sq.m., of which 561 sq.m. are water surface.

Physical Features.—Topographically, Iowa lies wholly in the prairie plains region, part of it having been overrun by the great ice sheet of the glacial epoch. For the most part the surface is that of a prairie tableland, moderately rolling, and with a general but scarcely perceptible slope, which in the eastern two-thirds is from north-west to south-east, and in the western third from north-east to south-west. Elevations above the sea range from between 1,200 to 1,600 ft. in the north-west to 500 ft. and less in the south-east, the highest point being in Osceola county, the lowest at Keokuk. In the southern half of the State the height of the crests of the divides is very uniform. The northern half, because of glaciation, is more broken and irregular. Elevations, usually rounded, mingle with depressions, some of which are occupied by small shallow lakes or ponds. But the most marked departures from the prairie surface are in the north-east and south-west. In the north-east the whole of Allamakee and parts of Winneshiek, Fayette, Clayton, Delaware, Dubuque and Jackson counties form the only driftless area of the State. In that region cliffs frequently rise almost vertically from the banks of a river to a height of from 300 to 400 ft.; and from the summit of the cliff to the crest of the divide, a few miles distant, there is another ascent of 300 ft. or more, terminating occasionally in knob-topped hills crowned with small cedar. Moreover, the largest streams have numerous tributaries flowing circuitously between steep if not vertical cliffs or in deep craggy ravines overlooked by distant hills. In the west, southward from the mouth of the Big Sioux river, extends a line of moundlike bluffs, usually free from rocks, rising abruptly from

the flood plain of the Missouri to a height varying from 100 to 300 feet. A broad water-parting extending from Spirit lake, on the northern border, nearly south to within 60 m. of the southern border, and thence south-east to Wayne county in the south central part of Iowa, divides the State into two drainage systems. That to the east, comprising about two-thirds of the whole area, is drained by tributaries of the Mississippi, of which the Des Moines,

KEOKUK DAM, IN IOWA, 4,360 FT. IN LENGTH, OPENED IN 1913

the Skunk, the Iowa with its tributary the Cedar, and the Wapsipinicon are the largest. These streams of long courses and easy fall are frequently pebbly in the north, but muddy in the south. Their valleys are broad at their sources, well drained, and gently sloping in the middle of their courses, but becoming narrower and deeper towards their mouths. The region to the west of the divide is drained by tributaries of the Missouri, mostly short streams taking their rise from numerous rivulets, flowing quite rapidly over muddy beds through much of their courses, and in the bluff belt along the Missouri having steep but grassy banks 200 ft. in height or more.

Climate.—The climate is one of great extremes of heat and cold, with a dry winter and a usually wet summer, the prevailing wind of winter being north-west, while in summer it not infrequently blows from the south-west. Both the midwinter isotherm of Montreal and the midsummer one of Washington, D.C., pass through the State. The mean annual temperature is 48° F; the average range of extremes per year is about 136° F; while the greatest extremes recorded are from -47° F in 1912 to 113° F in 1901, a difference of 160 degrees. The average mean annual temperature at Cresco in Howard county, near the north-east corner of the State was 44.3°, while at Keokuk in the south-east corner it was 52.2 degrees. As the isotherms cross the State, especially in the north, their tendency is to move south-west. The rainfall is also very unequal in distribution throughout the year, as between the same periods of different years, and as between the different parts of the State. While the mean annual precipitation is 31.97 in., about 71% of this falls during the six months from April 1 to Oct. 1, or 10% in winter, 23% in autumn, 28% in spring and 39% in summer. May, June and July are the three wettest months. At the same time extremes during the four most critical crop months, from May 1 to Sept. 1, have ranged from 6.75 in. to 27.8 inches. Within any one year the precipitation is in general usually less in the western part of the State than in the eastern; the western part also is marked by having a still greater percentage of its rain in spring and summer than has the eastern. The unequal distribution throughout the State is in large measure caused by local showers. Though the average frost-free growing season is from May 31 until Oct. 1, killing frosts may occur later or earlier. Injury to crops from drought and hot winds has occurred about two or three times in a decade, but liability to injury of the crops from excessive rainfall and hailstorms is greater than that from a deficiency of moisture.

Soil.—Its depth, together with its porous nature, makes the fertile soil of Iowa capable of withstanding the extremes of wetness and dryness remarkably well, and it is perhaps true that, taken as a whole, no other State in the Union has a superior soil for agriculture. Certainly no other has so many acres of improved land, or so large a proportion—from 85% to 90%—of its land subject

to cultivation. The soil is of four kinds: till or drift, alluvial, loess or bluff, and geest. The dark drift, composed chiefly of clay, sand, gravel, boulders and lime, is both the soil and subsoil of the greater part (about 66%) of the State, being especially predominant in the north and north-west. The alluvial soil, composed of what has been washed from other soils, together with decayed vegetable matter, covers about 6% of the surface of the State, and is found in the river bottoms, particularly in the Missouri; it varies much in fertility. The loess soil, chiefly a mixture of porous clay and carbonate of lime, forms the bluffs bordering the bottom lands of the Missouri and is common in the north-east. Its fertility is not inferior to that of the better drift. Geest is found particularly in the north-eastern part of the State; it covers less than 1% of the area of the State.

ADMINISTRATION

Constitution.—There is comparatively little in the political institutions of Iowa dissimilar to those of other States of the Union; they show in recent years a tendency towards greater centralization—in boards, however, rather than in individual officers. The Constitution now in force was adopted in 1857, the Constitution of 1846 having been superseded chiefly on account of its prohibition of banking corporations. The present one admits of amendment by a vote of a majority of the members of both houses of the legislature, followed by a majority vote of the electors in the State voting on the amendment; and by this process it was amended in 1868, 1880, 1884, 1904, 1908, 1916 and 1926. The present Constitution also provides that the question, "Shall there be a convention to revise the Constitution and amend the same?" shall be submitted to the people once every ten years (beginning with 1870); but the vote taken in accordance with this provision was never in the affirmative until 1920, when it was—yes: 279,652; no: 221,763. The 39th general assembly, however, failed to provide for a Constitutional convention. The suffrage now belongs to all citizens of the United States at least 21 years of age who shall have resided in the State for six months, and in some one county 60 days preceding an election, except idiots and persons insane or convicted of some infamous crime. The franchise was conferred on negroes by an amendment adopted in 1868, and on women by the Federal amendment adopted in 1920. Prior to 1904 elections were annual, but by an amendment of that year they became biennial.

The central executive and administrative authority is vested in a governor, a lieutenant governor, an executive council, several boards and a few other officers. The governor and the lieutenant governor, who are elected for a term of two years, shall be at least 30 years of age and shall have been for two years immediately before their election residents of the State. Under the territorial Government when first organized the governor was given an extensive appointing power, as well as the right of an absolute veto on all legislation. This resulted in such friction between him and the legislature that Congress was petitioned for his removal, with the outcome that the office has since been much restricted in its appointing power, and the veto has been subjected to the ordinary United States limit; *i.e.*, it may be overridden by a two-thirds vote of both houses of the legislature. The superintendent of public instruction and the three railroad commissioners are elected for terms of four years; the attorney general for a term of two years. Most of the heads of the numerous boards and commissions are appointed by the governor with the approval of the executive council or the senate. The governor, however, is himself a member of the executive council as well as of some important boards or commissions, and it is in this capacity that he often has the greatest opportunity to exert power and influence. His salary is \$5,000 per annum (with \$600 for house rent and \$1,200 as a member of the executive council). The executive council, composed of the governor, secretary of State, auditor of State and treasurer of State, all elected by the people for a term of two years, has extensive powers. It supervises and audits the accounts of State departments, directs the taking of the census, transfers cities from one class to another in accordance with census returns, constitutes the board for canvassing election returns, classifies railways, as-

sesses railway and other companies, constitutes the State board of equalization for adjusting property valuations between the several counties for taxing purposes, supervises the incorporation of building and loan associations, appoints the board of examiners of mine inspectors, and has many other powers.

In 1911 the office of commerce counsel was created, the incumbent to be appointed by the board of railway commissioners and

to serve as expert counsel for that board. In 1913 the department of insurance was created, and in 1917 a State banking department and the office of superintendent of banking. In 1915 a State board of audit and a State board of accountancy were created, and the office of document editor was established to relieve the secretary of State. The road administration was reorganized in 1913 when the general assembly established a highway commission consisting of the dean of engineering of the State college of agriculture and mechanical arts, and two appointed members. The highway commission was again altered in 1927 by increasing the number of its members to five and by giving it complete control over the primary road system. Highway legislation in 1919 divided the highways into primary and secondary systems, and

FARM VALUES (LAND AND BUILDINGS) PER ACRE OF LAND IN FARMS. THE LINE ACROSS EACH COLUMN SHOWS THE AVERAGE VALUE FOR THE UNITED STATES

arranged for the distribution of Federal and State aid funds for the hard surfacing of primary roads.

The State legislature, or general assembly, composed of a senate and a house of representatives, meets in regular session the second Monday in January in odd numbered years at Des Moines. Senators are elected for a term of four years, one from each of 50 senatorial districts, the term of one-half expiring every two years. Representatives are elected for a term of two years, one from each of the 99 counties, with an additional one from each of the counties (not exceeding nine) having the largest population; the ratio of representation and the apportionment of the additional representatives from the larger counties are fixed by the general assembly.

Judiciary.—The judiciary consists of a supreme court of 7 judges, and a district court of 69 judges, from one to five in each of 21 districts. The supreme court has three sessions a year, and each district court judge is directed to hold at least one session a year in each county of his district. No two district court judges may sit together on the same case. The supreme court has original jurisdiction in certiorari and mandamus cases, and appellate jurisdiction in cases sent up from the lower courts. It also has the power to pass on the constitutionality of State laws. The district court has general, original and exclusive jurisdiction in all matters civil, criminal and probate not expressly conferred on an inferior court, and may hear appeals from inferior courts, boards or officers.

For purposes of administration and local government the State is divided into 99 counties, each of which is itself divided into townships that are usually 36 sq. miles. The township may be divided into school districts and highway districts, but in these matters option has resulted in irregularity. Each county has its own administrative boards and officers. The board of supervisors, consisting of not more than seven members, elected for a term of three years, has the care of county property and the management of county business, including highways and bridges; it fixes the rate of county taxes within prescribed limits and levies the taxes for State and county purposes. Other officers of the county are: auditor, treasurer, clerk, recorder, sheriff, attorney, engineer, coroner and superintendent of schools. All are elected for a term of

two years, except the engineer and superintendent of schools, who are appointed. The officers of the township are three trustees, a clerk, an assessor, two justices of the peace and two constables. The trustees are elected for a term of three years, the other officials for two years. All taxable property of the State, that of corporations for the most part excepted, is assessed by the township assessor.

The municipal corporations are civil divisions quite independent of the county and township system. They are divided into cities of the first class, cities of the second class and towns, besides a few cities with special charters. Cities of the first class are those having a population of 15,000 or more; cities of the second class, a population of at least 2,000 but less than 15,000; all other municipal corporations, except cities with special charters, are known as incorporated towns. The commission plan of government, authorized in 1907 for cities of 25,000 or more inhabitants, was extended to cities of 2,000 or more inhabitants. According to the *Iowa Official Register 1927-28*, eight cities had organized under the commission plan: Burlington, Cedar Rapids, Des Moines, Fort Dodge, Keokuk, Mason City, Ottumwa and Sioux City. Commissioners are elected on a non-partisan ticket for a term of two years. In 1915 the general assembly passed acts allowing cities not exceeding 25,000 inhabitants to organize their municipal government under the city manager plan. By 1927, 12 municipalities had organized under this plan. The four cities Camanche, Davenport, Muscatine and Wapello are governed under special charters. All other municipalities are governed under the mayor-city council plan.

Under the laws of Iowa a wife enjoys property rights equal to those of her husband. The expenses of the family, including the education of the children, are chargeable alike upon the property of either or both. Otherwise, the wife may control her property as if single, and neither is liable for what are clearly the debts of the other. In case of the death of either, one-third of the property of the deceased becomes that of the survivor. A homestead cannot be conveyed or encumbered without the consent of both husband and wife, if held by a married man; and a homestead, to the value of \$500, is exempt from liability for debts post-dating the purchase, unless for improvements on the property.

Population.—The population of Iowa (State census) was 2,419,927 on July 1, 1925, and, according to the U.S. census estimate, 2,428,000 on July 1, 1928. The native whites of native parentage, in 1920, numbered 1,528,553; those of foreign or mixed parentage, 629,981; and the foreign-born whites, 225,647. The larger foreign groups in the order of their numerical strength were: Canadians, Italians and Mexicans. The negro population was 19,005. There were in 1920 43.2 inhabitants per square mile as against 40 in 1910. In 1920 the urban population was 36.4% of the whole. There were 18 cities having a population of 10,000 or more in 1920.

Finances.—The taxing system of Iowa includes a general property tax, an inheritance tax, a tax on insurance companies, a cigarette sales tax, a gasoline tax of two cents per gallon and other taxes for special purposes. The auditor's report for the fiscal year from July 1, 1925, to June 30, 1926, showed balances of \$1,642,608 in the general fund and \$2,324,982 in the trust fund on July 1, 1925. The receipts to the trust fund were \$11,650,157 and to the general fund \$16,407,850. The disbursements from the two funds, for the fiscal year, were \$28,026,002. The balances in both funds on June 30, 1926, were \$3,984,340. The chief expenditures from the general fund were for educational and charitable institutions. By far the greater part of the trust fund was expended on the primary road system. The assessment of property for 1925 showed real estate and town lots having an adjusted actual value of \$3,294,922,534,

personal property other than moneys and credits valued at \$376,725,254 and live stock valued at \$155,333,113. On June 30, 1926, the floating debt was \$141,497.89 and the bonded debt \$18,700,000, incurred to pay a bonus to World War veterans.

Education.—The first step toward establishing a system of public schools dates from the first session of the territorial legislature in 1838, but owing to the lack of funds for support the system was not established on a working basis until after 1850.

At the head of the whole system is the State superintendent of public instruction, assisted by a board of educational examiners. The county administration is in the hands of a board of education and a superintendent. The county superintendent is elected for a term of three years by a convention of presidents of each school township, consolidated independent and city independent school districts. The county board of education consists of six members elected for a term of six years and the county superintendent. Each school district has its separate board of education or trustees. The school revenue is derived from the State's permanent school fund, which grew out of land granted to the State by the Federal Government and from local or district taxation. School attendance was first made compulsory by legislative action in 1902. Subsequent acts have extended the period of school attendance to 24 consecutive weeks every year for children between the ages of seven and sixteen. State aid became an important factor in the development of public schools in the period following 1910. Legislation granted such aid to large centrally located, consolidated schools, which replaced small scattered ones. At the close of 1920 there were 430 consolidated districts, including about 25% of the area of the State and taking care of approximately 50,000 pupils. In 1911 State aid was granted by law to high schools organizing normal training of rural teachers. In 1917 a State board for vocational education was established to take advantage of the provisions of the Smith-Hughes law offering Federal aid for vocational education. A law, enacted in 1919, provided for part-time schools for the benefit of children between the ages of 14 and 16 working on employment certificates. The establishment of these schools was required where there were 15 eligible pupils in the district, and attendance became compulsory.

The total school population between five and seventeen years of age, inclusive, in 1926, was 601,283, of whom 556,270, or 86.1%, were enrolled in public, and 45,013, or 7.7%, were in private and parochial schools. In the public schools 444,376 were enrolled in the kindergarten and elementary schools; and 111,894 in secondary schools. The total number of teachers employed was 25,206. The average number of days attended per pupil enrolled had increased from 121.4 in 1910 to 148.3 in 1924. The total school expenditure for 1926 was \$57,288,000; a sum per caput based on population 5 to 17, inclusive, of \$94.38.

For advanced education Iowa has 26 universities and colleges. The State-supported institutions of higher education are the State university of Iowa at Iowa City (1847), the Iowa State college of agriculture and mechanical arts at Ames (opened in 1869) and the Iowa State teachers' college at Cedar Falls (1876). The State also maintains a school for the deaf at Council Bluffs, and a school for the blind at Vinton. The enrolment for the academic year 1923-24 (nine months) was as follows:—State university, 6,151; Iowa State college, 4,147; Iowa State teachers' college, 2,933; Iowa School for the Blind, 113; Iowa School for the Deaf, 292. All of the State-supported educational institutions are under the management of a single board of control known as the State board of education. The members of the board, nine in number, are appointed by the governor for six-year terms, subject to approval by the senate. The board chooses from outside its own members a finance committee of three members. The committee selects its chairman and secretary.

Educational institutions not supported by the State include: Iowa Wesleyan university (Methodist, 1842) at Mount Pleasant; Grinnell college (opened in 1848 as Iowa college, Congregational) at Grinnell; Coe college (1880) at Cedar Rapids; Drake university (1881) at Des Moines; Cornell college (Methodist, 1857) at Mount Vernon; Upper Iowa university (Methodist, 1857) at Fayette; Luther college (Norwegian Evangelical Lutheran, 1861)

All Other Land in the State

at Decorah; Des Moines university (Baptist, established in 1865 as Des Moines college) at Des Moines; Penn college (Friends, established in 1873) at Oskaloosa; Parsons college (Presbyterian, established in 1875) at Fairfield.

Charities and Corrections.—The charitable, penal and reformatory institutions of the State are all under a board of control of State institutions, composed of three members appointed by the governor and approved by two-thirds of the senators, careful provision being made also to prevent the board from becoming subject to either political party. The institutions under its charge include a Soldiers' Orphans' home at Davenport; a Soldiers' home at Marshalltown; an institution for feeble-minded children at Glenwood; an industrial school for boys at Eldora; an industrial school for girls at Mitchellville; a State sanatorium for the treatment of tuberculosis at Oakdale; Mount Pleasant State hospital at Mount Pleasant; Independence State hospital at Independence; Clarinda State hospital at Clarinda; Cherokee State hospital at Cherokee; hospital for female inebriates at Mount Pleasant; hospital for male inebriates at Independence; State penitentiary at Fort Madison; men's reformatory at Anamosa; women's reformatory at Rockwell City; hospital for epileptics and school for feeble-minded at Woodward; and a juvenile home at Toledo. The board of control of State institutions has supervisory and inquisitorial powers over all county and private institutions in the State in which the insane are kept, and over homes for friendless children maintained by societies or institutions. In 1907 the general assembly passed a law under which the indeterminate sentence was established in the State, and the governor appoints a board of parole of three members, of whom one must be an attorney and not more than two are to belong to the same political party.

THE STATE'S PRODUCTS

Industry, Trade and Transportation.—The superior qualities of the soil, together with the usually warm and moist months of spring and summer, make Iowa one of the foremost States in the Union in agriculture and stock raising, especially in the production of Indian corn, oats, hay and eggs, and in the raising of hogs, horses, dairy cows and poultry. Of the State's 858,698 persons engaged in profit-earning occupations in 1920, 327,124 were engaged in agriculture, 176,522 in manufacturing and mechanical industries and 169,201 in trade and transportation. Of the total farm acreage of 34,094,075 in 1925, 21,470,564 ac., or about 63%, were in actual cultivation. The average size of Iowa farms was 162 acres. The tenure distribution for the State's 210,899 farms was as follows:—owners 100,714, relative renters 31,298, renters 63,323, both own and rent 14,664, unclassified 900. According to estimates of the Iowa weather and crop bureau, the total value of farm products in 1925 was \$1,054,225,378; the distribution being \$513,953,000 for crops of all kinds, \$121,000,000 for dairy products, \$75,000,000 for eggs and poultry, \$2,215,000 for wool and \$342,057,378 for live stock shipped out in excess of the amount shipped in.

Indian corn is by far the chief crop, more than half of the cultivated area being devoted to its culture. In 1925, the 11,130,000 ac. planted in Indian corn had an average yield of 43 bushels per ac., the total yield being 478,590,000 bu. valued at \$268,010,000. The grain second in importance was oats, which, from 6,089,000 ac. and an average yield of 40.5 bu. per ac., produced 246,604,000 bu. valued at \$78,913,000. Both winter and spring wheat are raised, but wheat is a minor crop, its total value in 1925 being about \$8,500,000. As a producer of cultivated hay, Iowa ranks among the leading States. The yield from the 3,152,000 ac. devoted to all varieties of cultivated hay was 4,098,000 short tons valued at \$55,323,000. Other crops that had a value in excess of \$1,000,000 in 1925 were: barley, \$3,251,000; timothy seed, \$2,300,000; clover seed, \$1,216,000; potatoes, \$12,288,000; wild hay, \$3,150,000; pop-corn,

\$2,280,000; sweet corn, commercial crop, \$2,036,000; fruit crop, \$7,500,000 and garden truck, \$5,750,000. Iowa is not only a great feeding State for live stock shipped into the State, but ranks high as a breeding State. In 1925, Iowa led the other States of the Union in the number of swine and horses raised. There were marketed that year 10,940,322 native swine valued at \$236,739,507; 1,539,555 native cattle valued at \$97,305,961; 441,247 native sheep valued at \$5,419,826; 35,508 horses valued at \$2,592,084.

Iowa's first settlement was a mining camp, but this event proved to be no index to her future importance as a mineral producing State. The early worked lead and zinc mines about Dubuque are little worked at present, and these products are of small significance in comparison with the State's total mineral output. The value of all products, in 1925, gave the State the rank of 26th among the States of the Union, or .77% of the total mineral wealth of the Nation. Coal, mined in 20 counties extending from the south-east along the Des Moines river and three counties in the south-west, was the chief mineral product. The total production for the State in 1925 was 4,714,843 short tons, valued at \$14,807,000. The product second in importance was cement, 4,856,849 bbl. valued at \$8,674,563 having been produced in 1925. Clay products were manufactured to the value of \$5,703,537. In the production of gypsum the State ranked second, its output for 1925 having been 800,127 short tons valued at \$6,734,271. The producing area is confined to about 50 sq. m. in the vicinity of Fort Dodge in Webster county. Other products of commercial value were sand and gravel and building stone. The total value for all mineral products in 1925 was \$38,420,203.

The manufactures of Iowa deal chiefly with the products of the farm. Meat packing is the most important, the product of this industry amounting in 1925 to \$213,741,084 or an increase of 610.7% compared with the \$30,074,070 product in 1905. Next in importance is the manufacture of dairy products, the value of which in 1925 was \$78,110,309, or a gain of 419% from the products in 1905. The manufacture of food preparations was the industry third in importance, its value in 1925 having been \$42,532,872. The State's great railway systems gave rise to the industry next in importance—the construction and repair done in steam railway shops. In 1925 the work done in 61 railway shops was valued at \$31,529,993. Other industries which had a product in excess of \$10,000,000, in the order of their importance, were:—printing and publishing, \$30,903,936; washing machines, clothes wringers, etc., \$25,447,152; corn syrup, oil, starch, \$22,600,279; bakery products, \$22,193,496; foundry and machine-shops, \$21,345,826; planing mills, \$20,995,214; flour and grain-mills, \$15,138,899; canned and preserved fruits and vegetables, \$14,056,363; poultry killed and dressed, \$11,441,891. Manufacture of lumber, once the chief industry of Clinton and other cities along the Mississippi, dropped to minor importance when log rafts ceased to be floated down from Wisconsin and Minnesota. The State ranked first in the product of pearl buttons, with Muscatine the centre of the industry. The chief shell supply came from the Mississippi and tributary Iowa rivers. In 1925 the industry gave employment to 2,284 persons working at 43 plants, and had a value of \$5,679,112. The 1925 census of manufactures identified 83 separate industrial groups within the State. The 3,270 industries engaged 74,976 wage-earners and had a product valued at \$757,771,477.

Transportation is afforded chiefly by steam railways, of which the State had 9,814 m. in 1925. Scarcely a farm is more than 6 or 8 m. from a railway station; and only three other States have a greater mileage—Texas, Illinois and Pennsylvania. The great period of railway building in Iowa came during the 25 years immediately following the close of the Civil War, the railway mileage being only 655 in 1860. The several roads are under the management of 22 companies, but the chief systems are the Chicago, Burlington and Quincy; the Chicago and Northwestern; the Chicago, Milwaukee and St. Paul; the Chicago, Rock Island and Pacific; the Atchison, Topeka and Santa Fe, the Great Northern, the Illinois Central, the Union Pacific and the Wabash. Electric inter-urban railways are of importance for freight and passenger service. In 1908 about 225 m. of such railways were in operation; and

GROWTH OF POPULATION, 1840-1925. SHOWING ALSO (DOTTED LINE) THE NATIVE WHITE POPULATION

in 1926 the mileage was 518.87, a slight decrease from the years immediately previous. Including the street railways, there were 22 companies, operating 958 miles of track, in 1925. Transportation facilities by water are afforded by the Mississippi river. With the canal constructed by the U.S. Government between Keokuk and Montrose and the channel improvements at Clinton, there has been a revival of river traffic. Iowa has long had a State highway system, but it was not until 1919 that the highways were classified as primary and secondary. At the end of 1926 the highway commission controlled 6,653.7m. of road, of which 3,469.6m. were surfaced. During that year 498.7m. of new surfacing were laid. The Lincoln highway traverses the State, passing from Clinton in the east to Council Bluffs in the west, where it passes into Nebraska.

HISTORY

Iowa, as a part of the Mississippi valley, was taken into the formal possession of France in the year 1682; in 1762 as a part of the western half of that valley it was ceded to Spain; in 1800 it was retroceded to France; in 1803 it was ceded to the United States. From 1804-05, as a part of the District of Louisiana, it was under the government of Indiana Territory; from 1805 to 1812 it was a part of Louisiana Territory; from 1812-21 it was a part of Missouri Territory; from 1821-34 a part of the unorganized territory of the United States; from 1834-36 a part of Michigan Territory; from 1836-38 a part of Wisconsin Territory. In 1838 Wisconsin Territory was divided, the western portion being named Iowa, and out of this the State with its present bounds was carved in 1846.

The name Iowa was taken from a tribe of Siouan Indians (probably of Winnebago stock) which had dwelt in that part of the country for some time and were still there when the first white men came—the Frenchmen, Marquette and Joliet, in 1673, and Hennepin in 1680. Early in the next century the Sacs and Foxes, vanquished by the French in Michigan, retreated to the westward and largely supplanted the Iowas.

Thither also came Julien Dubuque, a French Canadian, to trade with the new occupants. He discovered lead mines, on and near the site of the city which now bears his name. In 1788 he obtained an Indian grant of about 21 sq.m., established a settlement of miners, and continued his mining operations, together with a trade in furs, until his death in 1810. The Indians would not allow others to work the mines, and were upheld in this by the United States troops, especially from 1830 to 1832. But the war which Black Hawk instigated was concluded in 1832 by a cession to the United States of nearly 9,000 sq.m., embracing much of this region. In spite of the act of Congress of 1807 prohibiting such settlements, the frontiersmen rushed in to mine and to farm, and established a Government through voluntary associations. Proceedings of these associations which related to claims to land were later recognized by the United States authorities; those relating to the establishment of schools were tolerated for a time by the State Government. Iowa separated from Wisconsin in 1838 on account of lack of courts for judicial relief, and the question of applying for admission into the Union as a State was voted on as early as 1840, the Territory in that year having a population of 43,112. The measure was defeated then, as it was again in 1842, by those who most wished to avoid an increase of taxes. In 1844, however, a convention was called, a Constitution framed and application for admission made. The question of boundaries, raised by the question of slavery,

then caused delay, but the territory became a State in 1846.

The Whigs had steadily opposed applying for admission, but the Democrats carried it through, and remained in power until 1854. Since 1857 the State has been preponderantly Republican in all national campaigns except in 1912, when a split in the party gave the electoral vote to Wilson, the Democratic candidate. With two exceptions, in 1889 and 1891, when liquor and railroad legislation were the leading issues, Iowa has elected a Republican State Administration. Within the dominant party, however, there has been a tendency towards the formation of two opposing elements, the more radical seeking the promotion of the "Iowa Idea," which in substance was to further the expansion of the trade of the United States with the rest of the world through the more extended application of tariff reciprocity, and at the same time to revise the tariff so as to prevent it from "affording a shelter to monopoly."

In 1882 an amendment to the Constitution was passed prohibiting the manufacture and sale of intoxicating liquors within the State. The supreme court, in April 1883, pronounced this amendment invalid on the ground of irregularity in recording it, whereupon the legislature provided for a like prohibition in an ordinary statute. Attempts to execute this were, however, so unsuccessful that it was succeeded by a law imposing the "mulct tax," which required the payment of \$600 in quarterly instalments for a licence to sell liquors, and placed a lien for the whole amount on the real property in use for the business. The vital portions of the "mulct tax" law were repealed by the general assembly in 1915, thus restoring statutory prohibition in Iowa, but a prohibitory amendment to the State Constitution was voted down by the election in Oct. 1917. The 18th (Prohibition) Federal amendment was, however, ratified by Iowa Jan. 15, 1919. In 1916 a constitutional amendment extending suffrage to women was submitted to the electors, but was defeated. The Federal suffrage amendment was adopted by the legislature in 1920.

The general assembly in 1913 passed an employers' liability and workmen's compensation act, and a mothers' pension act, providing for the granting to widowed and indigent mothers of sums not to exceed \$2 per week for each child under 14. In 1915 the Perkins law was passed, providing free treatment for crippled children of poor parents. In 1917 an appropriation was made by the general assembly for the erection and equipment of a hospital at Iowa City for such children. Two years later the general assembly provided that indigent adults as well might be sent to Iowa City for free medical and surgical treatment. In 1917 the general assembly established at Iowa City a child-welfare station.

The farm bureau movement in Iowa was an important development. By 1917 organizations among farmers were numerous, and in that year the general assembly passed an act providing that where a farm-improvement association in any county had among its members 200 farmers or farm owners and had raised \$500 in annual subscriptions, the county board of supervisors could contribute \$2,500 for the employment of a county agent. A law in 1919 modified the amount and terms of payment by the county, and made the contribution mandatory. The movement gained rapid headway, county associations being established for the betterment of both social and economic conditions and the improvement of agricultural methods. In 1920 there was a farm bureau in each county and two in Pottawattamie county, and a membership of over 100,000. There was also considerable growth within the State of a farmers' educational and co-operative union which had more than 20,000 members in 1920.

IOWA, STATE UNIVERSITY OF, an institution of higher learning, situated in Iowa City, Ia. It was organized by an act of the legislature in 1847. Instruction was begun in the spring of 1855, but the first regular collegiate session did not open until the autumn of 1856. Because of financial reasons, the university maintained only a normal department during the two years 1858-60. Since that time new departments, schools and colleges have been added to the original college of liberal arts. The law department was established in 1868, the medical department in 1870, the dental department in 1882 and the department of pharmacy in 1885. All these are now colleges. The graduate college was added in 1900 and the college of engineering in 1905. The school of education, created in 1907, became the college of education in 1913; and a school of commerce, established in 1914, became the college of commerce in 1921. In addition to these nine colleges now functioning, a preparatory department was maintained from the organization of the university until 1879; a homeopathic medical department, later a college, from 1876 to 1919; and a college of fine arts from 1911 to 1915. Within the college of liberal arts is the school of music and the school of journalism. Within the college of medicine is the school of nursing. A summer session, begun in 1900, has become an important part of the university. The extension division was organized in 1913; the Iowa Child Welfare Research Station in 1917; and the division of physical education in 1924. Enrolment in the reserve officers' training corps maintained at the university is compulsory for men students in the colleges of liberal arts, engineering and pharmacy during their freshman and sophomore years.

The university is the capstone of the public school system of the State. It is under the direction of a State board of education of nine members appointed by the governor, with the approval of the senate, for a period of six years. The faculty contains more than 500 men and women and the student enrolment for 1927-28 was 9,249. Funds for the institution are derived to some extent from the sale of lands originally donated for its support by the U.S. Government, but the greater part of its support comes from the appropriations made biennially by the general assembly. For the biennium 1927-29, the amount set aside for the university was \$4,091,003.20.

The central building of the university campus is the beautiful Old Capitol, which was begun in 1830 and served as the capitol of Iowa from 1841 until 1857, when Des Moines became the capital of Iowa and the capitol building was turned over to the university. Around this building are grouped some 50 buildings on a campus of over 300 ac. lying on both sides of the Iowa river. The latest additions to the material equipment of the university are the medical laboratories and hospital, built by the joint contribution of the State of Iowa and the Rockefeller Foundation at a cost of nearly \$5,000,000. The university library contains more than 360,600 volumes. Closely associated with the work of the university is the State Historical Society of Iowa, with a library of over 74,000 titles. (W. A. J.)

IOWA CITY, a city of south-eastern Iowa, U.S.A., on the Iowa river, 120m. E. of Des Moines; the county seat of Johnson county. It is on Federal highways 32 and 161; is served by the Cedar Rapids and Iowa City (electric) and the Rock Island railways, and is a station on the transcontinental air-mail route from east to west, with an airport that is brilliantly illuminated at night. The population in 1925 (State census) was 15,289. The city lies

in a natural amphitheatre, almost surrounded by hills and bluffs. It has various manufacturing industries, and is the seat of the University of Iowa (q.v.). of the library of the State Historical Society, and of the State sanatorium for the treatment of tuberculosis. In 1839 Iowa City was selected as the seat of government of the newly created Territory of Iowa, and it remained the capital until 1857, when Des Moines was chosen in its stead, because of its more central position. The old State capitol is now the headquarters of the administration of the university.

IPECACUANHA. The root used in medicine under this name is obtained from *Psychotria* (or *Uragoga*) *Ipecacuanha*, a rather small shrubby plant of the family Rubiaceae. It is a native of Brazil, growing in clumps or patches in moist shady forests from 8° to 22° S., and is also found in Colombia and probably in Bolivia. The great value of the drug in dysentery led to attempts to acclimatize the plant in India. Like other dimorphic plants, ipecacuanha ripens seeds best when cross-fertilized, and presents various forms.

Ipecacuanha root occurs in pieces about two or three lines in thickness, of a greyish-brown or reddish-brown tint externally, having a ringed or annulated surface (see illustration), and exhibiting a white or greyish interior and a hard wiry centre. It has a faint rather musty odour and a bitterish taste. The variety imported from Colombia and known as Cartagena ipecacuanha differs only in its larger size and in being less conspicuously annulated. Ipecacuanha owes its properties to the presence of rather more than 1% of the alkaloid emetine, which occurs only in the cortical portion of the root. It is a white amorphous substance, with the formula $C_{20}H_{30}NO_2$. It has a bitter taste, no odour, and turns yellow when exposed to air and light. There are also present a volatile oil, starch, gum and a glucoside, which is a modifica-

- B. Fruits
- C. Long-styled flower
- D. Longitudinal section through a short-styled flower

tion of tannin and is known as ipecacuanhic acid. The dose of the powdered root is $\frac{1}{4}$ to 2 grains when an expectorant action is desired, and from 15 to 30 grains when it is given as an emetic, which is one of its most valuable functions.

Ipecacuanha powder is a powerful cutaneous irritant, even causing pustulation. When inhaled it causes violent sneezing and a mild inflammation of the nasal mucous membrane, resembling a common cold in the head. Small doses stimulate the secretions of the mouth, stomach, intestine and liver. The drug, therefore, increases appetite and aids digestion. Toxic doses cause gastro-

enteritis, cardiac failure, dilatation of the blood-vessels, severe bronchitis and pulmonary inflammation closely resembling that seen in ordinary lobar pneumonia. In this respect and in its action on the skin, the drug resembles tartar emetic. Ipecacuanha is very frequently used as an expectorant in cases in which the bronchial secretion is deficient. Its diaphoretic properties are employed in the *pulvis ipecacuanhae compositus* or Dover's powder, which contains one part of ipecacuanha powder and one part of opium in ten.

Other plants to which the name of ipecacuanha has been popularly applied are American ipecacuanha (*Gillenia stipulacea*), wild ipecacuanha (*Euphorbia Ipecacuanha*), bastard ipecacuanha (*Asclepias curassavica*), Guiana ipecacuanha (*Boerhavia decumbens*), Venezuela ipecacuanha (*Sarcostemma glaucum*), and ipecacuanha des Allemands (*Vincetoxicum officinale*). All these possess emetic properties to a greater or less degree.

IPEK, one of the two largest towns in Montenegro, Yugoslavia. Pop. (1921) 14,762, almost entirely Albanian. The town lies in a fertile plain on which tobacco is cultivated. Ipek is surrounded by trees and gardens, while a pleasant stream runs through it. Nearly every house is provided with a watch-tower. It is situated on the road from Jakova to Prizren, and from its position, it is destined to form a connecting link for trade with Serbia. Ipek was formerly the centre of the Serbian Church, the archbishop having been raised to the patriarchate by Stephen Dushan (1331-55). It was suppressed in 1459, restored in 1557 and finally abolished by the Turks in 1767. On the heights above the town stands the 13th century monastery, the seat of the patriarchs until 1690, and the church, which dates from the 16th and 17th centuries. Here are the marble tombs of many church dignitaries, and the marble throne of the patriarchs. After the fall of Belgrade in 1521 many of the inhabitants migrated to Hungary, and in 1690 there was a second migration there led by the patriarchs. The town was captured by the Montenegrins in the Balkan Wars (1912-13) and ceded to Montenegro by the Treaty of Bucharest (1913). In the World War thousands of refugees fled here. It was here too, that on the long march to Scutari, the broken Serbian army called a halt to destroy their guns, which they rolled over a precipice.

IPHICRATES, Athenian general, son of a shoemaker, flourished in the earlier half of the 4th century B.C. He is chiefly known for the use he made of lightly armed troops (peltasts); he increased the length of their weapons, and improved their mobility by reducing their defensive armour. He also paid special attention to discipline, drill and manoeuvres. With his peltasts Iphicrates seriously injured the allies of the Lacedaemonians in the Corinthian War, and in 392 (or 390) dealt the Spartans a heavy blow by almost annihilating a battalion of hoplites (Diod. Sic. xiv. 91; Plutarch, *Agessilaus*, 22). He was later transferred from Corinth to the Hellespont, where he was equally successful. After the peace of Antalcidas (387) he assisted Seuthes, king of the Thracian Odrysae, to recover his kingdom. About 378 he was sent with a force of mercenaries to assist the Persians to reconquer Egypt; but a dispute with Pharnabazus led to the failure of the expedition (Diod. Sic. xv. 29-43). On his return to Athens he commanded an expedition in 373 for the relief of Corcyra, which was besieged by the Lacedaemonians (Xenophon, *Hellenica*, vi. 2). On the peace of 371, Iphicrates returned to Thrace, and fought for Cotys in a war against Athens for the possession of the Chersonese. The Athenians, however, soon pardoned him and gave him a joint command in the Social War. He and two of his colleagues were impeached by Chares, the fourth commander, because they had refused to give battle during a violent storm. Iphicrates was heavily fined. He died about 353.

There is a short sketch of his life by Cornelius Nepos; see also C. Rehdantz, *Vitae Iphicratis, Chabriae et Timothei* (1854); Bauer, *Griech. Kriegsaltert.* in Müller's *Handbuch*, 4, § 49; and histories of Greece, e.g., Holm, Eng. trans., vol. iii.

IPHIGENEIA, daughter of Agamemnon (q.v.); not mentioned in Homer, but by some absurdly identified with the Iphianassa of II. ix, 145, who was alive and well some ten years after Iphigeneia's supposed death. As she is constantly represented

as connected in some way with Artemis, and as Iphigeneia ("mightily born," i.e., "great princess") is a title of the goddess; as, moreover, she has substituted for her one of Artemis' beasts (see below), it is in no way impossible that originally she was a by-form of the goddess herself; but the question is obscure. Agamemnon had vowed to sacrifice to Artemis the fairest thing that should be born in a certain year, meaning the handsomest beast; but in that year Iphigeneia was born. Another story is that he or Menelaus had offended Artemis in some way. As a result, Artemis stayed the Greek fleet at Aulis on its way to Troy, by calm or contrary winds, and Calchas discovered that only the sacrifice of Iphigeneia would appease the goddess. Iphigeneia therefore was sent for on pretence of marrying her to Achilles; at the last moment the goddess relented and substituted a hind, bear, or bull for the victim, whom she spirited away to the land of the Tauri (Crimea). Here she became priestess of Artemis and as such had to sacrifice all strangers. At last Orestes (q.v.) and Pylades arrived; by a stratagem, she fled with them taking the image of Artemis, which Orestes had been sent to fetch. They left it somewhere in Greece; among places claiming to have the true statue and some remnant of the old rites of human sacrifice were Brauron in Attica, where a pretence was made of cutting a man's throat before the goddess, and Sparta, where boys were beaten till the blood came, in the ritual of Artemis Orthia.

Iphigeneia was variously said to have died and been buried at Brauron or Megara, and to have been transported to Leuce, where she was wedded to Achilles, or even to have been transformed into the goddess Hecate (q.v.).

See Stoll in Roscher's *Lexikon* (bibl.); L. R. Farnell *Greek Hero-Cults* (1921); H. J. Rose *Handbook of Greek Mythology* (1928).

IPOMOEA, a large genus of mainly climbing herbs or shrubs of the convolvulus family (Convolvulaceae, q.v.), containing about 400 species. It includes the sweet potato (*I. Batatas*), the cultivated morning glory (*I. purpurea*) and the jalap (*I. purga*).

IPSUS, BATTLE OF, 301 B.C. This, named "the battle of the kings," was the great clash in the wars of Alexander the Great's "Successors," which shattered Antigonos's attempt to reconsolidate the Macedonian empire. Hard-pressed in Thessaly by Demetrius, the son of Antigonos, Cassander turned the tables by a stroke of true genius. Keeping only a minimum of force, he despatched his ally, Lysimachus, to invade Asia Minor and arranged with Seleucus to advance from Babylon on Antigonos's rear. The combination and concentration against the heart of the opposing power succeeded, and forced Demetrius to evacuate Greece and sail home to his father's aid. The armies of Antigonos and Demetrius on the one hand, and of Lysimachus and Seleucus on the other met at Ipsus in Phrygia. Antigonos had 70,000 foot, 10,000 horse and 75 elephants; the allies only 64,000 foot, 10,500 horse, but 480 elephants. At the outset of the battle Demetrius with the cavalry charged and dispersed the opposing cavalry, but, pressing the pursuit too far, found himself cut off by the enemy's elephants. But instead of assaulting Antigonos's army, thus stripped of his cavalry, Lysimachus demoralized it by threat of attack and by fire until it began to melt—part going over to the allies. Then only did Seleucus launch a strong body at the position occupied by the enemy's command. Borne down by this charge, Antigonos died, crying vainly "Demetrius will come and save me." If the victory is memorable in military history as one of the outstanding triumphs of the war elephant, its greater political consequence was to ensure the disappearance of any central power and the dismemberment of the Graeco-Macedonian world. (See **DIADOCHI, WARS OF**.)

IPSWICH, a town of Stanley county, Queensland, Australia, on the river Bremer, 23½ m. by rail W. by S. of Brisbane. Pop. (1926) 20,526. It is the centre of a rich and populous agricultural mining and manufacturing district. Coal outcrops on the surface and is worked on the banks of the river. There are woollen factories, saw-mills, and foundries and large railway workshops at North Ipswich. The first settlement was made here in 1829; the town was incorporated in 1860. It has

grown immensely during the first quarter of the 20th century.

IPSWICH, municipal, county and parliamentary borough and county town of Suffolk, England, 69 m. from London by L.N.E.R. Pop. (1921) 79,371. It stands on the left bank of the river Gipping. In the lower and older portion of Ipswich are a few antiquarian remains. Sparrowe's house (1567), and Archdeacon's Place (1471) are two old gabled houses, while Wolsey's Gateway (1528), a Tudor brick building, is the only remnant of the Cardinal's foundation to supply scholars to his great college (Cardinal's College, now Christ Church) at Oxford. The older churches are all towered flint-work structures, wholly or mainly Perpendicular in style, with the exception of St. Peter's, which is principally Decorated, with a Norman font of marble. They include St. Margaret's with a beautiful oak Tudor roof, elaborately painted *temp.* William and Mary; St. Mary-at-Key (or Quay), with a similar roof. St. Lawrence and St. Clement's. The museum is of some importance. The grammar school, dating at latest from 1477, was refounded by Queen Elizabeth in 1565. There is a picture gallery in the Tudor mansion (1549) in Christchurch Park. Industries include engineering and agricultural implement works, railway plant works, electrical apparatus, paper, furniture and the making of artificial manures, and clothing. Imports are principally grain, timber, petroleum and coal; exports agricultural machinery, railway plant, artificial manures and oil cake. There is an Anglican bishopric of St. Edmonsbury and Ipswich. The parliamentary borough returns one member.

Prehistoric finds include a Roman villa, and a Saxon settlement. In 991 the town (*Gipeswic*, *Gipeswich*) was sacked by Vikings. It owes its prosperity to its situation on a harbour admirably suited for trade with the Continent. In 1200 King John granted the burgesses their first charter, the town to be held at fee-farm, with a gild-merchant. The burgesses were definitely incorporated in 1464 and re-incorporated in 1665 under a charter which remained in force up to its modification by the Municipal Act of 1835. The cattle market and provision market are the prescriptive right of the corporation. A September fair, still held in 1792, was in the hands of the corporation in the 17th century. Large ironworks were established late in the 18th century. The wool and cloth trade of the 14th and 15th centuries was superseded by the manufacture of sailcloth, now represented by the sacking industry.

IPSWICH, a town of Essex county, Massachusetts, U.S.A., 28m. N.N.E. of Boston, on both sides of the Ipswich river and fronting on Ipswich bay; served by the Boston and Maine railroad. The population was 6,055 in 1925 and is increased in the summer by some 2,000 seasonal residents. The town was settled under the name of Aggawam in 1633 and was incorporated in 1634 as Ipswich. During the early days of the colony it was little inferior to Boston in wealth and influence, and frequently took an opposing position on public questions. Ipswich was the home of several of the leading writers of the colonial period, including the Rev. Nathaniel Ward (1578-1652). A number of houses date from the 17th and 18th centuries. In the oldest, the John Whipple House, is the interesting collection of the Historical society. The Choate bridge, built in 1764, is the oldest arched bridge in America.

IQUIQUE, a city and port of Chile, capital of the province of Tarapacá, 820m. N. of Valparaíso, in 20° 12' 15" S., 70° 11' 15" W. Population (1920) 37,421. The coast here runs due north and south and the city is built on a narrow level plain between the sea and bluffs, the latter rising steeply 2,000ft. to the level of the great desert plain of Tarapacá, celebrated for its rich deposits of nitrate of soda. Facing the city is the low barren island of Serrano, or Iquique, which is connected with the mainland by a stone causeway 1,500ft. long, and shelters the anchorage from southerly storms. A mole extending from the north-eastern end of the island affords further protection. The city is laid out on the rectangular plan, with broad streets and large squares. Water is brought by pipes from Pica, 50 miles distant. Iquique is a city of much commercial importance and is provided with banks, substantial business houses, newspapers, clubs, schools, railways, tramways, electric lights, telephone lines, and steamship and cable communication with the outside world. It exports iodine and immense quantities of nitrate of soda obtained from the desert

region of the province. A large number of vessels are engaged in the nitrate trade, and Iquique ranks as one of the two leading ports of Chile in the aggregate value of its foreign commerce. It is connected by rail with the inland town of Tarapacá and various mining centres, and through them with the ports of Pisagua on the north, and Patillos on the south. Iquique was an insignificant Peruvian fishing settlement until 1830 when the

BY COURTESY OF W. R. GRACE & CO.

LARGE NITRATE FACTORY OF W. R. GRACE & CO. NEAR IQUIQUE

export of nitrate began. In 1863, the town was nearly destroyed by an earthquake, in 1875 by fire, and again, in 1877, by earthquakes, a fire and a tidal wave. It was occupied by the Chileans in 1879 in the war between Chile and Peru, and was ceded to Chile by the treaty of Oct. 20, 1883.

IQUITOS, a tribe of South American Indians. It is divided into many branches, some on the river Tigre, others on the Nanay. Missionary efforts have failed and they remain savages, worshipping figures carved in the shape of birds and beasts. They brew the Indian fermented liquor *chicha* better than any of the neighbouring tribes, flavouring it with the shoots of some plant which has the effect of an opiate.

IQUITOS, a city and river port of Peru, and capital of the great department of Loreto, on the left bank of the upper Amazon near the mouth of the Rio Nanay, 2,330 m. from the Atlantic, 73° 11' 25" W., 3° 45' 23" S. During the height of the rubber boom (1906-1912) the population reached 15,000, but has declined to less than 10,000. Iquitos is about 400 ft. above sea-level, on the low wooded banks of the river. The climate is hot and damp. As a Peruvian, not Indian town, it dates from 1863 when the first government buildings were erected. The chief buildings are the prefecture, custom house, municipal palace, churches, schools, clubs and barracks; Iquitos is the centre of a military region. Houses are mostly adobe roofed with thatch or tile, streets wide, but with few exceptions badly paved.

The city has regular service from the Atlantic by the Amazon River Steamship Co., Ltd., controlled by the Booth line, and is the distributing point for all up-stream tributaries navigated from Iquitos by smaller craft. The city now has direct wireless communication with Lima and other stations, and an air mail service to San Ramón (Junín) one day from Lima. Rubber has been until recently the basis of the city's prosperity (*see* LORETO). Exports include tobacco, cotton, wax, tortoise-oil, sarsaparilla, vanilla, gold and Panama hats. Tile and brick are manufactured, and there are a few other small industries. The city has electric lights, steam tram, cinemas and telephones which connect with the wireless station at Itaya, a suburb. Water and sewage systems are under construction. Iquitos dates officially from 1863, when it had a population of 431, though there had been a white settlement there for more than half a century. The opening of the Amazon to navigation added immensely to the importance of the city and made it the commercial entrepôt of Eastern Peru.

IRAN, the great plateau between the plain of the Tigris in the west and the valley of the Indus in the east, the Caspian Sea and the Turanian desert in the north, and the Persian Gulf and the Indian Ocean in the south, surrounded on all sides by high mountain ranges with a great salt desert in the centre. The modern name Iran (in middle-Persian, Eran) is derived from the ancient *Aryāna*, "the country of the Aryans." Eratosthenes limited the name of Ariana to the south-eastern part of Iran, and excluded Persia, Media and Bactria, and therein he is followed by Strabo

(ii. 78, 130. xv. 720 ff.; Pomp. Meia i. 3; Pliny, *Nat. Hist.* vi. 113, 116, xii. 33). Pliny (*Nat. Hist.* vi. 93) confounds it with Aria, Areia, Pers. Haraiva, i.e., the district of Herat; but Strabo himself says (xv. 724) that some extended the name to the Persians, Medes, Bactrians and Sogdians, as they all spoke the same language with slight variations. (Cf. xv. 727 and i. 66, xi. 523.)

For the ethnography and history of Iran see PERSIA.

IRANIAN LANGUAGES AND PERSIAN. Three successive stages in the history of the Iranian languages, viz., ancient, middle and modern, in Persian, the principal branch of the group, correspond with epochs of national vicissitudes. Old Persian was used on the monuments of the Achaemenian dynasty (558-339 B.C.) destroyed by Alexander the Great. Middle Persian is known from the Parthian, or Arsacid period (250 B.C.-A.D. 225), even more from the Sassanian times (A.D. 225-651), terminated by the Arab conquest and domination. With the Persian Renaissance (ninth century A.D.) modern Persian, with some unsubstantial changes, appears again as still a living language. Other Iranian idioms passed through stages similar to those of Persian.

Ancient Iranian Languages.—Of the Median language we know only one word (*ῥάκα*, "dog") preserved by Herodotus (I. 110) and several personal names. This material suffices to place Median among Iranian (northern Persian) idioms. Of the Old Scythic group of languages (Scythic and Sarmatian) only personal names in Greek inscriptions, found in South Russia, have come down to us. The only ancient Iranian languages really known to us are Avestic and Old Persian.

The former is the language of the Zoroastrian sacred books. By earlier European scholars it was improperly called Zend, which term designates only the commentary to the Avesta, written in Middle Persian (see below). The age of the Avesta is dubious. Two parts of it are clearly distinct: the so-called Gāthās are more or less at the same linguistic stage as the most ancient Vedic hymns of Old Indian. These archaic fragments, though perhaps not directly or not wholly emanating from Zoroaster (q.v.), are authentic documents of the religious reform brought about by the Prophet of Iran. The greater part of the Avesta, the so-called "recent or younger Avesta," is a collection of texts of varying antiquity and is characterised by a gradual simplification and a lax use of the grammatical forms. The Avesta when codified (towards A.D. 379) had long been a dead language known to the priests alone. In its present state the Avesta has the size of the *Iliad* and *Odyssey* put together. The original home of Avestic is doubtful.

Some scholars regarded it as the old Bactrian language but no decisive arguments can be drawn from the text itself. Others (Darmesteter, and recently, on linguistic evidence, Tedesco) place the home of Avestic in north-western Persia (Media), though, even in this case, Avestic could not be simply identified with Old Media. The alphabet of the Avesta has no claim to antiquity, being the late Pahlavi script (see below) reformed by the addition of the missing signs. For linguistic purposes these late characters are in some cases definitely misleading.

Old Persian was used in the cuneiform inscriptions of the Achaemenian kings. The text is usually accompanied by translations into Elamitic and Akkadian (Assyro-Babylonian). The most important document is the famous inscription of Darius the Great (522-486 B.C.) on the rock of Bihistūn, near Kermanshah, which was first read and published by Sir H. Rawlinson in 1846-47.

Aryan Languages.—Within the Indo-European family of languages, Old Iranian and Sanskrit form the division of "Aryan" languages. (The terms Aryan and Irān have a common origin.)

How near Old Iranian is to Sanskrit is seen from the comparison of a phrase translated from Avestic into Sanskrit:

Avestic:	yō vō āpō	vanguhiš	yazaitē	ahurānīš	ahurahe
Sanskrit:	yō vō āpō	vasviṣ	yajātē	asurānīṣ	asurasya
Avestic:	vahištābyō	zaoθrābyō		sraēštābyō	...
Sanskrit:	vasiṣṭhābhyō	hōtrābhyō		sreṣṭhābhyo	...

The original Avestic words, undisguised by the alphabet, would be still nearer to Sanskrit.

The principal phonetic distinctions of Iranian from Indian are:

1. original *s* becomes *h* in Iranian; 2. to Indian voiced and voiceless aspirates correspond respectively Iranian voiced stops or spirants; 3. Iranian has *z*, absent in Indian; 4. Iranian diphthongs *ai*, *au* are found in Indian as *ē*, *ō*, etc. See above and the following examples:

Sanskrit	Avesta	Old Persian	Modern Persian
<i>Sindhu</i> (Indus)	<i>Hindu</i>	<i>Hindu</i>	<i>Hind</i>
<i>Asura Medhās</i>	<i>Akura Mazdāh</i>	<i>Ahuramazdā</i>	<i>Hurmuзд</i>
<i>bhūmī</i> (earth)	<i>būmī</i>	<i>būmī</i>	<i>būm</i>
<i>kratu</i> (insight)	<i>xratu</i>		<i>xirad</i>
<i>hasta-</i> (hand)	<i>zasta-</i>	<i>dasta-</i>	<i>dast</i>
<i>agea-</i> (horse)	<i>aspa-</i>	<i>asa-</i>	<i>ašp</i>

Later on the two branches, Indian and Iranian, have diverged widely.

Middle Persian.—Until the beginning of the 20th century only "Pahlavi," among the Iranian languages, was known at the stage of linguistic development, where the original wealth of forms had disappeared but the language had not finally simplified its characteristics. This Sassanian Middle Persian was chiefly known under two aspects: *a.* as scarce rock-inscriptions, and *b.* as a written language.

a. The former are cut in an uncouth but sufficiently clear script. The earliest of them (before +A.D. 300) gives usually two versions of the same text: the one is identical with the "book-Pahlavi"; the other, considerably different, was surnamed "Chaldaeo-Pahlavi," an ill chosen term which was vaguely supposed to cover the surviving dialect of Parthian times.

b. The written Pahlavi ("book-Pahlavi") is the language of the later Zoroastrian literature coming down to the ninth century A.D., when the language was certainly dead. Pahlavi literature consists mainly of commentaries on the Avesta and treatises on religious subjects (in all some 587,000 words), and only to a much smaller degree (41,000 words) treats of historic and other lay matters. This literature is written in an exceptionally ambiguous and unsuitable alphabet in which many characters are confused (one sign for *g*, *d*, *y*; one sign for *v*, *n*, *r*, etc.). Owing to such complications the name of the Supreme Deity Ōhrmazd was long read by error Anhōmā. Further difficulties are created by the use of numerous Semitic ideograms: it has long been discussed, whether *yōm* ("day" in Semitic) was to be read as it stood, or replaced by its Persian equivalent *rōzh* (as the Latin *viz.*, is read in English *namely*). This latter opinion was accorded universal recognition only after 1900. The defects of the Pahlavi alphabet caused the Zoroastrians to transcribe some of their texts in later Avestic characters, in which case these writings are called Pāzand.

Discoveries After 1900.—Of exceptional importance have been the Middle-Persian documents (Christian and Manichaean) found, chiefly by the German expeditions in Turfan (Chinese Turkestan) and deciphered by Prof. F. W. K. Müller. All these fragments are written in a special alphabet, derived, as usual, from Semitic (Aramean), but clearly distinguishing single characters. The words formerly known only in Semitic disguise are here written in plain Persian. Besides many additions to vocabulary and grammar, the new texts have fully confirmed the existence in Middle Persian of two parallel dialects. The one, the descendant of Old Persian, was spoken in the south (Fars) and the other probably in the north-west (or north and west) of Persia. This latter has some special traits in common with Avestic but is not its lineal offspring. The southern dialect must have been originally called Pārsik, while the term Pahlavik (another form of the name Parthian) belonged specially to the north-western dialect. The divergence of the dialects can then be traced down to modern days. Some differences will appear from the table on page 593.

In 1924 Professor Herzfeld published an entirely revised text of the largest of all Sassanian inscriptions, that of the ruins of Paikuli, near Sulaimaniya. Meanwhile, an original Middle Persian document of the earlier Arsacid times was found in Avroman (Persian Kurdistan), together with some important Greek parchments of that epoch (published by E. H. Minns in 1915). The Persian document was finally deciphered by H. S. Nyberg (1923).

Middle Persian		Modern languages	
North-Western	Southern	N.-W. dialects	Persian
<i>zān</i> - (know)	<i>dān</i>	<i>zān</i> (Kurdish)	<i>dān</i> -
<i>zhan</i> (woman)	<i>zan</i>	<i>zhin</i> (Kurdish)	<i>zan</i>
<i>das</i> (ten)	<i>dah</i>	<i>dos</i> (Simnani)	<i>dah</i>
<i>puhr</i> (son)	<i>pus</i>	<i>pūr</i> (Persian)	<i>pus</i> - <i>ur</i>
		doublet	
<i>zīd</i> (heart)	<i>dil</i>	<i>purd</i> (Kurdish)	<i>pul</i>
		<i>zir</i> (Kurdish)	<i>dil</i>

The existence of a different branch of the Middle Iranian languages has now been demonstrated. To it belongs the Sogdian language of which the documents were chiefly discovered and deciphered by the French scholars, and another called by some German scholars (Leumann) "nordarisch," but now supposed to be Sacian, *i.e.*, the language of the people Sacae. These two languages possess some traits in common; moreover, Sogdian has particularly close affinities with the "Scythic" group of the Iranian languages (*see above*).

Modern Languages.—All present Iranian languages display in different degrees a tendency towards an analytic stage (simplification of the sounds and in morphology, to the use of new auxiliary tenses, etc.).

Of these languages by far the most important is the literary Persian, as found in the extensive Persian literature and in the present day speech of the more educated classes of the Persian-speaking countries. Modern Persian is a direct descendant of the southern middle Persian, but it has borrowed many words in the north-western form, and numerous Arabic and Turkish elements. It is written in Arabic characters. Though Modern Persian is one and the same language, local variations, spoken in Persia, Afghanistan, India and Russian Turkistan (Tājiki), are considerable.

Parallel to literary Persian, in most Persian towns, and especially villages, special dialects are in use. The dialects of Fars, Luristan, Khurasan and perhaps Kerman, belong to the same southern (south-western?) group as the literary Persian. On the other hand, very numerous and different vernaculars represent the remains of former north-western idioms. Such are the local dialects of the Caspian provinces, the language of the Kurds (spread over a vast area and sporadically found in northern Syria and even close to Angora in Asia Minor), the language of the Baluches and of isolated groups (as those of Kashan, Simnan, etc.).

Among modern Iranian languages of the "eastern" and "north-eastern" group are the Afghan language (Pushtu [*q.v.*]), Ōrmuri, the various dialects of the Pamir group (Shughni, Wakhi, Munjani, etc.), Yagnobi (a modern descendant of the Middle Sogdian), Ossetic (spoken in the heart of the Caucasian mountains south of Vladikavkaz, survivor of the once powerful "Sarmatian" group [*see above*] spoken in South Russia). In 1927 some new written material was found in the Khvārizmian language which seems to have been in use in the oasis of Khiva as late as the 14th century A.D. This Khvārizmian must be a survival, or a descendant, of a sister-language of the Middle Sogdian.

BIBLIOGRAPHY.—Detailed monographs on the Iranian languages with complete bibliography will be found in vol. i. of *Grundriss d. Iran. Philologie*, edited by Geiger and Kuhn, Strassburg (part I., 1895–1901) (part II., 1898–1901), supplement on Ossetic (1903). Later important works are: Bartholomae, *Altiranisches Wörterbuch* (Strassburg 1904); Bartholomae, *Zum altiranischen Wörterbuch, Indogerm. Forschungen*, Beiheft to vol. xix. (Strassburg 1906); Meillet, *Grammaire du vieux perse* (1915). For the discovery of Middle-Persian texts see F. W. K. Müller, *Handschriften-Reste aus Turfan*, I.–II., *Sitzungsber. Berl. Akad.*, 1904 (the texts have been re-edited by Salemann, *Manichäische Studien*, I., *Mémoires de l'Académie de St. Pétersbourg*, VIII., No. 10 [1908], pp. 1–172; *see also* Salemann's further articles); texts in "nord-arisch" (Sacian) have been published chiefly by Leumann in 1912, 1919 and 1920; Gauthiot, *Essai de Grammaire sogdienne*, I. (1914–23, second volume to be published in 1929); P. Tedesco, *Dialektologie d. westiranischen Turfantexte*, *Le Monde Oriental*, Uppsala, XV. (1921) fasc. 1–3 (a general survey of western dialects); Grierson, *Linguistic survey of India*, vol. x., *Specimens of languages of the Eranian family* (Calcutta, 1921); also vol. i. pg. 27; Herzfeld, *Paikuli, Monument and inscription of the early history of the Sasanian Empire* (1924).

The best theoretical grammar of Modern Persian is Salemann and Zhukovski's *Persische Grammatik* (1889). In the Otto-Gaspey-Sauer series (Heidelberg) have appeared two detailed practical grammars by St. Clair Tisdall (in English) and S. Beck (in German). Philott, *Higher Persian Grammar* (Calcutta 1919), 935 pp.; F. Rosen, *Shumā fārsi harf mizanid?* [Do you speak Persian?] (Leipzig 1890), several German and English editions. European dictionaries: Vullers, *Lexicon Persico-latinum* (Bonn, 1855), 2 vols. and an annex (complete and important for scientific work); Desmaisons, *Dictionnaire persan-français*, 4 vols. (Rome 1908–14); Steingass, *A comprehensive Persian-English Dictionary* (1892), 1,539 pp.; Abdullāh Ghaffārov, *Persidsko-russki slovar* (Moscow, 1914–17), 2 vols. (important phraseology). (V. F. M.).

IRANIAN RELIGION: *see* ZOROASTER and ZEND AVESTA.

'IRAQ. The modern mandated Arab kingdom of 'Iraq was formed after the World War out of the former Turkish vilayets of Mosul, Baghdad and Basra. It includes an area of over 140,000 sq.m. with a population according to the census of 1920 of 2,849,282. Of this number 1,146,685 were Sunni Mohammedans, 1,494,015 Shi'ah Mohammedans, 87,488 Jews, 78,792 Christians and 43,302 of other religions. The capital is Baghdad, pop. 1920, 145,000. Basra, the chief port, 70 m. up the Shatt el Arab from the Persian Gulf, has about 50,000 inhabitants. The region embraces not only the valley of Mesopotamia but also an important desert corridor stretching westwards to the boundaries of Transjordan. 'Iraq is bounded on the north by Turkey, on the west by Syria and Transjordan, on the south-west and south by Nejd and Kuwait and on the east by Persia. Owing to the nature of the country, the difficulties of water rights and raiding proclivities of the desert tribes the western and southern boundaries are by no means clearly defined. Cotton here is an irrigation crop. Before 1921 none was exported. No spectacular development has taken place, but a steady, healthy progress is shown. The whole of the cotton passes through the hands of the British Cotton Growing Association, who possess the only ginnery. The 1926 crop was 3,500 bales, of the value of £77,000. (For physical and economic geography *see* MESOPOTAMIA.) The British Empire is the mandatory power.

The terms of the mandate were never formally laid down by the League of Nations, but the relations between Great Britain and 'Iraq were defined in terms of a treaty concluded on Oct. 10, 1922, originally for a period of 20 years. This, however, was modified by a protocol dated April 30, 1923, in which it was agreed that the treaty should terminate upon 'Iraq being admitted to membership of the League of Nations and in any case not later than four years from the date of the ratification of peace with Turkey, when it was contemplated that the parties would conclude a fresh treaty for the regulation of their future relations. On Sept. 24, 1924, the League of Nations accepted this instrument as properly fulfilling the provisions of Art. 22 of the Covenant. By a further treaty ratified on March 30, 1926, and resulting from the decision of the League on the Mosul question, the period was again altered to 25 years (from Dec. 16, 1925), unless before the expiration of that period 'Iraq should be admitted to membership of the League of Nations.

The 'Iraq Government is a limited monarchy on the Egyptian model, with a king, a senate of 20 nominated members and a lower house of 88 deputies. The country is divided into three vilayets (provinces) comprising in all 14 liwas (divisions), the administration being represented in each liwa by a Mutessarif, who is assisted by a British official with advisory powers. The liwas are: *Mosul Vilayet*: Mosul, Arbil, Kirkuk and Sulaimaniyah; *Baghdad Vilayet*: Baghdad, Karbala, Diyala, Kut, Diwaniyah, Hillah and Dulaim; *Basrah Vilayet*: Basrah, Amara and Muntafik.

HISTORY

Nationalist Movement.—During the years from 1911 to the outbreak of the World War the Ottoman regime in the distant vilayets of Turkish Arabia showed marked deterioration. The last hope that any efficient administrative system might be established in Mesopotamia vanished with the fall in 1911 of Nazim Pasha, an energetic man of singular integrity, who had set himself to the intricate task before him with all the rude strength of a Turkish soldier of the old order. The Italian and

Balkan wars had weakened the central Government, while in the Arab provinces in particular the disappointment of hopes born of the constitution of 1908 was leading to a recrudescence of racial aspirations. Damascus and Beirut had long been centres of nationalist movements, and by the end of 1913, the secret society called the Ahd (the League) had extended its activities also to the three Mesopotamian vilayets.

The Mesopotamian Campaign.—The declaration of war was followed on Oct. 31, 1914, by a proclamation by the Political Resident in the Persian Gulf to local Arab rulers explaining that Turkey had entered the war only at the instigation of Germany and promising the chiefs who had enjoyed the protection of Great Britain that no act of that country should threaten their liberty or their religion. With these assurances they were satisfied. Before military operations had begun, Sir Percy Cox, whose efforts as British Resident during the previous decade had consolidated the British position on the Gulf, joined the force concentrated at Bahrein as chief political officer and on Nov. 6 when the British took Fao Fort and made their first landing on Turkish soil, he issued a proclamation in similar terms to the Arabs of Turkish Arabia. At this stage a determined attempt was made by the Ottoman Government to arouse Muslim fanaticism by the preaching of a Jihad, but it met with no response from the tribesmen and by Nov. 21 the Turks had abandoned Basrah, the British position on the Shatt-el-Arab was established and the valuable refinery of the Anglo-Persian Oil Company at Abadan rendered secure. On Nov. 22 British troops entered Basrah and, in the name of the general officer commanding in chief, Sir Percy Cox published a third proclamation assuring the inhabitants that Turkish rule was dead and that Great Britain came as their good friend and protector. The British arrival in Basrah was in fact greeted with acclamation by the terror-stricken populace and civil administration was at once inaugurated by the chief political officer under the orders of the G.O.C. In the same way, as success followed success, a large measure of civil law and order was gradually established close in the wake of the army.

The advance from Basrah to Baghdad is described under MESOPOTAMIA. A period of grave anxiety preceded the victory of Shu'aiba, on April 12, 1915, when a reverse would in all probability have involved the evacuation of 'Iraq by the British expeditionary force. After the retreat from Ctesiphon (Nov. 25, 1915) and the fall of Kut (April 29, 1916), the fate of 'Iraq again hung in the balance, but the vigorous re-organization of the force, now under the command of General Sir Stanley Maude, restored the foundations of victory, and Baghdad was occupied on March 11, 1917.

In the proclamation which General Maude issued on the occupation of Baghdad a definite promise was given that alien institutions should not be imposed, that Arab aspirations should be realized and that on those grounds the collaboration of Arab nobles, elders, and representatives, with British political officials, was essential. A further development of civil administration was made when in July 1917, Sir Percy Cox was appointed civil commissioner. The army and his country suffered great loss in the death from cholera on Nov. 10, 1917, of General Maude, whose distinguished powers as a military leader had earned the respect and admiration of 'Iraqis, but under Lieut.-general Sir W. R. Marshall, the success of British arms continued. Late in Nov. 1917 the northern Euphrates was occupied up to Ramadi, and in March 1918 up to Ana. In the same month, however, a serious incident occurred on the middle Euphrates. The holy towns of Karbala and Najaf were not only racked by internal feuds but both they and the adjacent tribesmen owned the sway of Persian divines to whom the secular interest of 'Iraq counted nothing. The Holy Places thus presented a fertile field for intrigue and when the Government of Occupation showed a determination to check the rapacity of the local headmen at Najaf, a plot, engineered from without, came to a sudden head with the murder of the newly appointed political officer. Sir Percy Cox was on his way home at the time to attend a conference in London but the situation was handled successfully by his locum tenens Colonel (later Sir Arnold) Wilson and the G.O.C. in chief. Though Najaf

was blockaded not a shot was fired, but the pressure exerted resulted in the handing over of the guilty by May 19. A court of specially qualified members condemned 13 of the accused to death, while over 100 were sentenced to transportation for life or shorter periods, but all of these latter were ultimately amnestied.

North-east of Baghdad, progress was hindered by the Russian débâcle, but when, at the end of June 1917, the upheaval which was taking place in Russia obliged the Russians to retire, the British force gradually drove the Turks from the vacated positions, occupying Khanaqin in Dec. 1917 and Kifri in April 1918. Kirkuk was reached in May and immediately a provisional Government under a local magnate, Shaikh Mahmud-al-Barzanji, was set up voluntarily in Sulaimaniyah in friendly co-operation with the British. But the exigencies of the Persian situation made it impossible for the general staff to maintain the position effectively and it was not until the final advance took place in Oct. 1918 that the occupation of the whole of the Mosul vilayet was effected.

THE ANGLO-FRENCH DECLARATION

Liberation of 'Iraq.—On Nov. 7, 1918, ten days after the signature of the Turkish armistice at Mudros, the British and French Governments issued a joint declaration of vital importance to the occupied Arab territories, stating their aims in the East to be:—

To complete the final enfranchisement of the peoples so long oppressed by the Turks, and the establishment of national governments and administrations, drawing their authority from the initiative and free choice of native populations.

The proclamation went on to promise encouragement and help in the establishment of native governments and administrations, alike in Syria and Mesopotamia. In the case of General Maude's earlier pronouncement made on the occupation of Baghdad, when the upshot of the war was still doubtful, the flamboyant sentiments expressed therein had been to a great extent discounted by the public as a natural form of propaganda, but the Anglo-French declaration, published after victory had been achieved, was taken in all seriousness. Had an early peace made it possible to give early effect to the policy therein enunciated all would have gone well. Unfortunately the inordinate delay which ensued over the peace negotiations and the wide promulgation of President Wilson's 14 points, with the potent element of self-determination, gave unbridled play to political speculation and stimulus to nationalist feeling. This was further encouraged by enquiries which the civil commissioner set on foot under instructions from H.M. Government, whether:—

- (i.) The people of 'Iraq were in favour of a united Arab State from the northern boundary of the Mosul vilayet to the Persian Gulf.
- (ii.) It should be under British tutelage.
- (iii.) It should be under an Arab amir.
- (iv.) In the latter case, whom would they suggest?

On the first point their replies were unanimously in the affirmative. In regard to the other three every variety of opinion was given. Unfortunately the conflicting character of the response had the effect of delaying a definite pronouncement of policy, and meanwhile other factors came into play. All this time the administration had remained patently alien; British forces had been cut down to a minimum and when in May 1920 the British Government announced their acceptance from the League of Nations of a Mandate over 'Iraq, the Damascus Government had already, in the absence of the Amir Feisal and contrary to his orders, begun encroachments. In answer to objections raised against the Mandate by a self-chosen committee in Baghdad, it was announced (June 20) that Sir Percy Cox would return in the autumn to establish a provisional Arab Government and call an Assembly, freely elected by the people, in consultation with which he would prepare an Organic Law. But nothing would then have satisfied the claims of the nationalist leaders, and on June 2, 1920, the turbulent Shiah tribes, encouraged by their religious leaders, broke into open revolt.

To restore peace and order was the first necessity. Troops were drafted in from India, and when Sir P. Cox reached Basrah on his return as High Commissioner (Oct. 1) the rebellion in its

main centres, the middle Euphrates, the Diyala and the adjacent part of Kirkuk district was already doomed to failure. By Nov. 10 it was found possible to establish, as a first step towards national government, a Council of State under the presidency of the venerable Naqib of Baghdad. This body represented all classes and sects of society. It gave immediate attention to the repatriation of 'Iraqi officers from Syria and the Hejaz; to the re-organization of civil government under 'Iraqi officials, greatly facilitated by the return of many experienced men from Turkey; and to the preparations of an electoral law and the formation of an army. It was the arrival of 'Iraqi officers who had served under the Amir Feisul which set on foot a specific movement in his favour in 'Iraq. He had been expelled from Syria by the French authorities in July 1920 and had since resided in England.

In March 1921 Mr. Winston Churchill, who had now become secretary of State for the Colonies, convened a conference at Cairo to which all British representatives in the Middle East were summoned. The first result of the conference was the publication of a general amnesty in May and at the same time an attempt was made to ascertain the wishes of the Kurdish provinces about their inclusion or non-inclusion in the 'Iraq State. The net result was that Sulaimaniyah elected to remain under the control of the High Commission, but the rest of the Kurdish population was content to look to the 'Iraq Government, subject to the promise of Kurdish officials and the local use of the Kurdish language.

Choice of King.—It was not until June that H.M. Government were in a position to make any clear announcement of policy as the result of the Cairo deliberations and towards the end of that month the Amir Feisul arrived in 'Iraq to offer himself to the inhabitants as a candidate for the throne. He was received with acclamation, and on July 11, the Council of Ministers passed a resolution declaring him king of 'Iraq, on condition that his government should be constitutional, representative, and democratic. But Sir Percy Cox thought it necessary to fortify himself by consulting the people and a referendum was carried out through the Ministry of the Interior, throughout the country, with the exception of Sulaimaniyah, with the result that 96% of the votes were cast in favour of the Amir Feisul, most of the townships and districts stipulating for the continuance of the British Mandate. The Amir Feisul was crowned king on Aug. 23, 1921, and entrusted the Naqib with the formation of his first cabinet.

TURKISH HOSTILITY

Troubles on Turkish and Arabian Frontiers.—The early years of King Feisul's reign were troubled without and within. To the north Turkish nationalism adopted an attitude distinctly hostile to 'Iraq. Turkish garrisons on the frontier were increased, the tribes flooded with propaganda, and the whole of Southern Kurdistan was kept in a ferment until finally in the spring of 1923 the Turks were ejected.

On the Arabian frontier, since the beginning of 1921, the operations of Ibn Sa'ud against Ibn Rashid had profoundly disturbed the nomad tribes. As early as April 1921 the Shammar of Ibn Rashid began to seek safety in 'Iraq, where a large section of the tribe resides. Their presence embittered relations between 'Iraq and Nejd, and after the fall of Ibn Rashid's capital, Hail, in Nov. 1921, Ibn Sa'ud's pretensions increased, and he claimed the allegiance of the Anizah on the eastern side of the Syrian desert, who had always been attached to 'Iraq. In March 1922, he permitted the leaders of his Akhwan, or Brethren, to attack the 'Iraq desert camel corps and the shepherd tribes grazing under its protection about 30m. south of the railway between Baghdad and Basrah. Heavy loss was inflicted.

Anti-Mandate Agitation: the Preliminaries of the 'Iraq Treaty.—These dangers on the frontier coincided with a serious divergence of views between the British and 'Iraq Governments as to the nature of their relations with one another. King Feisul and his prime minister asked for the complete abrogation of the unpopular "mandatory" relation and its substitution by a treaty of alliance, whereas the British Government were contemplating a treaty within the scope of the Mandate. The difference was largely technical, but it gave rise to great misunderstanding and

embittered controversy. It was even suggested that the attack by Ibn Sa'ud, who at the time was in receipt of a subsidy from Great Britain, had been instigated by the latter in order to expose the weakness of the 'Iraq Government. At this point the Shi'ah divines took a hand in the matter and summoned a conference at Karbala; nominally to consider measures of defence against the Akhwan, but really with the object of protesting against the British Mandate. The conference assembled, but the Sunni shaikhs held aloof, the wiser among the Shi'ahs nipped any subsidiary intentions in the bud, and the meeting confined itself to petitioning King Feisul to take steps against the Akhwan. But the heat engendered was not extinguished, and the anti-Mandate agitation continued throughout the summer, though in June the Council of Ministers accepted the treaty with Great Britain, subject to its acceptance in due course by the Constituent Assembly. On Aug. 16 the cabinet resigned, and Sir Percy Cox when paying an official visit to the king on the anniversary of his accession was greeted by an anti-Mandate demonstration. He demanded and received an instant apology, but at the same moment it was announced that the king was struck down with a dangerous attack of appendicitis and an immediate operation was necessary. Thus by a singular combination of circumstances, the country was left with no authority but that of the High Commissioner, who proceeded to use it. He issued a proclamation explaining the situation, arrested and deported certain agitators, and induced two of the Shi'ah divines to leave voluntarily for Persia. By Sept. 10, 1922, all agitation had died out and on Oct. 10 Sir Percy Cox and the Naqib signed a treaty of alliance between Great Britain and 'Iraq for a period of 20 years (British Treaty Series No. 2). Ratification, however, was delayed and negotiations over the subsidiary agreements dragged on until 1924.

No sooner was the internal situation stabilized than the north-eastern frontier again demanded attention. With Shaikh Mahmud in Sulaimaniyah and the Turks in Ruwandiz and its neighbourhood, effective administration had ceased east of Erbil, Kirkuk, and Kifri. In Oct. 1922 a measure decided on at the Cairo Conference was put into force and the air marshal, Sir John Salmond, assumed charge of all imperial forces in 'Iraq, ground troops, levies and air force. By his vigorous action he forced the Turks to retire to Ruwandiz. But the autumn of 1922 was the period of Mustafa Kemal's great triumph over the Greeks. It influenced both the Shi'ahs of the Euphrates and the tribes of the North. On Oct. 21, 1922, the king issued an Iradah ordering elections for the Constituent Assembly to begin; it was countered by a fatwah, signed by the Shi'ah divines of Karbala and Kadhimain forbidding participation in elections. In Nov. the Naqib resigned, and Abdul Muhsin Beg al Sa'dun formed a new cabinet. In the same month elections were held in Great Britain, during which a campaign was conducted against the fulfilment of British pledges to 'Iraq. Mr. Bonar Law's cabinet came in under obligation to consider the question, and Sir Percy Cox was summoned to London in Jan. 1923 to take part in the discussion. He left in charge Sir Henry Dobbs, who had come out as Counsellor to the High Commission in the previous December. The position of the British Government was extremely difficult, but a solution was found in the reduction of the term of the yet unratified treaty from 20 to a maximum of four years after the ratification of peace with Turkey (which took place on Aug. 6, 1924), with the prospect of renewal at the end of that period. The treaty would lapse in the event of 'Iraq becoming a member of the League of Nations. The protocol embodying this agreement was brought back by Sir Percy Cox on March 31, 1923, and signed on April 30.

Operations in Mosul.—Meantime, in March 1923, it had again become necessary to take vigorous steps against the Turkish threat in the north. The strong stand taken by Lord Curzon at Lausanne reacted on 'Iraq. Shaikh Mahmud, who was in league with the Turkish band at Ruwandiz, was dealt with, and in April, by a brilliant movement supported by air action, the Turks were ejected from Ruwandiz, and a Kurdish chief put in as Kaïmmakam under the Mutasarrif of Erbil. As it was not considered feasible for the time being to set up a local administration in Sulaimaniyah it was decided to give Shaikh Mahmud another chance of

rehabilitating himself, but in 1924 his intrigues made his expulsion again necessary. The Sulaimaniyah liwa became included in 'Iraq in March 1924 and sent representatives to the Constituent Assembly.

Settlement with Nejd.—In the winter of 1923-24 an attempt was made to settle the growing differences between 'Iraq and Nejd by a conference of representatives held at Kuwait under Colonel Knox. The main point of difference was the repatriation of Nejd tribes which had taken refuge in 'Iraq. The 'Iraq representatives rightly pointed out that apart from the violation of tribal custom involved, they had not the requisite force to constrain these unwelcome guests to return to their own country but they agreed to abide by stipulations considered satisfactory by the British Government. Though on lesser matters agreement was reached Ibn Sa'ud proved obdurate on the major issue, and just as the conference was about to reassemble, in March 1924, his followers carried out a brutal raid on the 'Iraq shepherd tribes. The conference thereupon broke up. Other raids occurred during 1924-25, and as a result, the 'Iraq Government made a determined effort to remove the tribes from the vicinity of the frontier.

Ibn Sa'ud likewise gave orders to his Akhwan leaders to desist from their raids. Finally, at the conference held at Bahra in the Hejaz between the Sultan and Sir Gilbert Clayton in Nov. 1925, a treaty was drawn up between 'Iraq and Nejd on the lines proposed by H.M. Government and the 'Iraq Government, at Kuwait.

Ratification of Treaty.—Sir Henry Dobbs and the 'Iraq Government had been engaged during the winter of 1923 in discussing the details of the agreements subsidiary to the treaty. These agreements were signed on March 25, 1924, and the instrument of alliance being thus complete, the Constituent Assembly was opened by the king on March 27.

THE TREATY ACCEPTED

The debates on the treaty and agreements continued until June 10. There was much misrepresentation but undoubtedly some solid ground for dissatisfaction at the heavy burdens imposed on 'Iraq by the obligation simultaneously to expand the army, redeem the capital cost of the railways, and shoulder a large share of the Ottoman debt. H.M. Government gave an undertaking that after the ratification of the treaty they would be prepared to reconsider certain of the financial obligations of 'Iraq towards Great Britain, and the debates were brought to a close by the announcement of the determination of the British Government to raise, at the June session of the League of Nations, the whole question of the continuance of their Mandate, and by the warning that failure to pass the treaty through the 'Iraq Assembly by June 10 would be regarded as a rejection. King Feisul and his Government clearly discerned the attendant risks, the cabinet called on its followers for support, and the treaty and agreements were accepted before midnight on the appointed date. The instrument was accepted by the League on Sept. 27, 1924, and was ratified by King George and King Feisul in the winter of 1924. The Constituent Assembly then passed the Organic and Electoral Laws, and was dissolved on Aug. 2, 1924. The question which now overshadowed all others was the settlement of the northern frontier with Turkey (*see* LEAGUE OF NATIONS; MOSUL).

It had not been considered advisable to disturb the proceedings of the Frontier Commission sent by the League of Nations to Mosul in the spring of 1925 by the holding of elections; on March 21, 1925, however, the Organic Law was promulgated and elections for the first parliament began. Yasin Pasha's cabinet had previously passed four notable measures, vital for the further prosperity and stability of 'Iraq. The first was the signature with the Anglo-Persian Oil Company of an agreement for the dredging of the Shatt-el-Arab. The second was a trade transit-agreement with Syria. The third was the granting to an international group, known as the Turkish Petroleum Company, of a concession for the development of oil in the Baghdad and Mosul vilayets; while the fourth was the signature of long term contracts with over a hundred experienced British advisers and technical officials.

The visit in April 1925 of the secretaries of State for the Colonies and Air gave opportunities for frank and valuable ex-

change of views, and also resulted in the adoption of a scheme which would provide for the speedier training of the 'Iraq army so that it may eventually assume responsibility for internal security and external defence.

Elections were completed by June 23, 1925, and Parliament met on July 16 in extraordinary session to consider the budget and certain necessary amendments to the Organic Law.

(G. BE.; P. Z. C.)

Second Treaty, Jan. 1926.—The award of the Council of the League on the Turco-'Iraq frontier question (*see* LEAGUE OF NATIONS) was accepted by 'Iraq with considerable relief, and in response to the Council's invitation to the British Government, negotiations for the conclusion of a new treaty were initiated towards the end of 1925. This instrument was to endure for a period of 25 years, or until such time as 'Iraq should become a member of the League. It was signed by the representatives of the two Governments on Jan. 13, 1926; accepted by the 'Iraq parliament on Jan. 18, by the British parliament on Feb. 18; and recognized by the Turkish Government in the preamble to a tripartite treaty concluded at Angora on June 5, 1926, between the representatives of Great Britain, 'Iraq and Turkey (Cmd. 2679). This latter treaty records the acceptance by the parties of the boundary-line adopted by the Council of the League; provides for the despatch of a boundary commission to trace it on the ground; lays down procedure for the amicable settlement of boundary disputes and the maintenance of tranquillity on the frontier; and finally provides for the payment to Turkey by the 'Iraq Government, for a period of 25 years, of 10% on all royalties received by the latter from the Turkish Petroleum Company and its subsidiaries. It may be mentioned that this important company reported its first successful boring experiment in the neighbourhood of Kirkuk in Oct. 1927 and promises to have a prosperous future.

Third Treaty, Dec. 1927.—The boundary commission provided for in the above instrument having successfully completed its labours by the autumn of 1927, the 'Iraq Government were encouraged to hope that the conditions necessary for admission to membership of the League of Nations, under Art. 1 of the Covenant, would now be considered fulfilled. King Feisul and his prime minister, Jaafar Pasha, accordingly journeyed to London in Nov. 1927 for the purpose of approaching the British Government as to the possibility of their supporting an application from the State of 'Iraq for admission, at the meeting of the League in Sept. 1928. The questions involved in this proposition were fraught with no little difficulty, relating mainly to the problem of national defence; King Feisul's Government considering that full military responsibility could only be met at the present juncture by the adoption of some form of conscription, a measure to which the British Government found it difficult to promise their support. On the whole, the British Government considered that it would not be possible for them to support 'Iraq's application for admission at such an early stage with the least chance of success. Short of that, however, some readjustment of the relations between 'Iraq and her Mandatory was adjudged to be possible, having regard to the undoubted progress made by the 'Iraq administration during the past two years, and this took the form of yet another treaty to replace that of Jan. 1926. While the main principles of the second treaty underwent little change therein, another step was taken towards the satisfaction of 'Iraqi aspirations by the formal recognition of 'Iraq as an independent State (Art. 1), and Great Britain further agreed, provided that the present rate of progress be maintained, to support the candidature of 'Iraq for admission to the League in 1932 (Art. 8). At the same time it was recognised that the existing military and financial agreements admitted of some revision of the progress made, and negotiations were accordingly opened for that purpose. Unfortunately, as they progressed, considerable divergence became apparent between the modifications pressed for by the more advanced nationalists in 'Iraq and the views of H.M. Government as to what would be safe and feasible. The main difficulty arose in connection with the fundamental question of national defence. Was the state of 'Iraq already capable, as her government claimed,

of taking full responsibility for national defence? If not, should she be called upon to bear the extra cost involved to H.M. Government by the necessity for keeping forces in Iraq?

Since the restoration of law and order progress has been made in archaeological exploration and research. Two important expeditions are at work, one on the site of Ur of the Chaldees, and the other at Kish, and in connection with them an archaeological museum has been established at Baghdad. (See also MESOPOTAMIA.)

Longrigg, *Four Centuries of Modern Iraq* (1925); Polson Newman, *The Middle East* (1926). (P. Z. C.)

Defence.—The military history of Iraq is bound up with that of Turkey (*q.v.*). British responsibility for the defence of the country is a legacy of the World War and the Covenant of the League of Nations under which a mandate for the well-being of the people formerly under the Turkish yoke was allotted to Great Britain on the conclusion of peace. The close of the World War found a British army, mostly of Indian troops, of a ration strength of over 204,000 in the country, pitted against about 29,500 Turks. The British troops were hastily withdrawn, and at the same time (1919) a frontier force of Iraq levies was raised with headquarters at Mosul. These levies were reorganized and redistributed in 1921, March 1922 and again in 1924. The cavalry were disbanded in 1927, and most of the infantry have already followed, leaving only 2 battalions, both of Assyrians, and a depot (March 1928). The Iraq levies number about 3,000 in all.

The present-day problem of the military defence of Iraq under treaties with Great Britain is of unique interest, in that defence has been entrusted mainly to British aircraft, thus minimizing the number of troops, and the whole placed under the control of the air force commander. The British garrison has been reduced to 2 battalions of Indian infantry. In addition to the Iraq levies, an Iraq army is in process of formation under British officers. The strength (1928) may be taken at about 10,300, organized in 3 cavalry regiments, 2 field and 3 pack batteries, and 7 battalions of infantry, with the usual military departments and details. There is a ministry of defence with an army headquarters working therewith, and the troops are distributed in 3 military areas, northern, eastern and southern. The Royal Air Force has 8 sections of armoured cars.

(G. G. A.)

IRAQ, a province of Persia, situated south of Hamadan and west of Qum. The district is an agricultural one—producing much grain, and grapes and raisins are of particularly good quality. The revenue in 1926–27 amounted to 1,450,876 krans (£ St.=45 krans). Sultanabad, the administrative centre, is situated 34° 6' N. and 49° 42' E., at an elevation of nearly 6,000 ft. on the Tehran-Qum-Khurramabad road, which is suitable for motor traffic, and it is also connected by a similar road with Hamadan.

IRBIT, a town of the Uralsk Area of the R.S.F.S.R. in lat. 57° 38' N., long. 63° 6' E., at the junction of the Irbit and Niza rivers which drain into the Tura, a tributary of the Irtish. The Niza is navigable as far as Irbit in spring. It is famous for its fair held since 1643 from Feb. 8 to March 10, the clearing house for Siberian furs, wools and hides, and for tea from the east. A large proportion of the fur comes from west of Lake Baikal and of the wool from the Kirghiz steppe: what is not sold is sent on to the fair at Nizhni-Novgorod. The skins include squirrel, rabbit, sable, ermine, brown bear, kolonok, grey wolf, fox, badger, black cat, Orenburg marmot, Petchora, Yenisei and Obdorsk white fox, reindeer, mink and marten, and sales amount to £730,000 to £830,000 per annum. Until Jan. 1917 the town was 80 m. from the railway, but in that year a branch from Sverdlovsk (Ekaterinburg) to the Tavda river was opened, which will ultimately link

up with Tobolsk. The Irbit fair was the first to be reopened (1922) after the 1914–21 war and civil war. The population was 20,064 in 1897, dropped to 9,647 in 1920, was 11,719 in 1926.

IRELAND, JOHN (1838–1918), American Roman Catholic prelate, was born at Burnchurch, County Kilkenny, Ireland, on Sept. 11, 1838. In 1849 he was taken to the United States by his parents, who settled at St. Paul, Minnesota Territory. After being educated in France for the priesthood, he returned to the United States in 1861; he was ordained at St. Paul and in the following year he accompanied the 5th Minnesota Volunteer Infantry south as chaplain. Subsequently he became rector of the cathedral at St. Paul. His appointment in 1875 as bishop of Nebraska was changed at the urgent request of Bishop Grace so that he might remain at St. Paul as bishop-coadjutor with the right of succession; at the same time he was made titular bishop of Maronea.

His liberal views gave him a wide influence and reputation both within and without the church, and he came to be looked upon as a leader of the "American" as distinguished from the "Roman" party in the clergy. Several of his administrative acts, notably his plan for the partial taking over of control of the parochial schools by the local authorities, were strenuously attacked. He was prominently identified with the planting of Catholic communities or colonies in the North-west, with the establishment of the Catholic university at Washington, and with the Catholic total abstinence movement. He published *The Church and Modern Society* (1896). He died at St. Paul on Sept. 25, 1918.

IRELAND, JOHN (1879–), English composer, was born at Bowdon, Cheshire, on Aug. 13, 1879, the son of Alexander Ireland, editor and proprietor of the *Manchester Examiner*. He studied at the Royal College of Music. His pianoforte trio (1908) was followed by the sonatas in D minor and A minor for violin and piano and a second trio in one movement. In 1913 appeared an orchestral work, *The Forgotten Rite*. His other works include *Decorations* (1914), and *Rhapsody* (1915), for piano; Four Preludes for pianoforte (1915); a trio in E minor (1917); a piano sonata in E (1919) and a series entitled *London Pieces* (1917–20) together with songs and church music.

IRELAND, WILLIAM HENRY (1777–1835), forger of Shakespearian manuscripts, born in London, was the son of Samuel Ireland, an engraver and author, and dealer in rare books and curios. In 1794 young Ireland, with his father, visited Stratford, where he met John Jordan, a local poet who had forged the will of Shakespeare's father. Seeing his own father's credulous interest, Ireland copied, in ink which had all the signs of age, Shakespeare's style and handwriting, and produced leases, contracts with actors, notes, receipts, a profession of faith and even a love letter to Anne Hathaway with an enclosed lock of hair, to the delight of his unsuspecting father, and the deception of many scholars. Ireland invented an ancestor "William Henry Irelande," to whom the documents had been bequeathed by Shakespeare in gratitude for rescue from drowning. At last the discovery of a whole new play named *Vortigern* was announced. Sheridan purchased it for Drury Lane theatre, and an overflowing house assembled on April 2, 1796, to sit in judgment upon it. But its one representation was greeted with shouts of laughter. Samuel Ireland the elder had published in 1795 the *Miscellaneous Papers and Legal Instruments under the Hand and Seal of William Shakespeare; including the Tragedy of King Lear and a small fragment of Hamlet* (dated 1796). He had the fullest belief in their authenticity, but the hostile criticism of Malone and others, and the unsatisfactory account of the source of the papers, made him demand a full disclosure from his son. Ireland at last confessed his fraud, and published (1796) an *Authentic Account of the Shakespearian MSS.*, and in 1805, a more elaborate *Confession*, entirely exculpating his father and making a full admission. The disgrace seems to have hastened the elder Ireland's death (July 1800). Ireland died on April 17, 1835.

The more interesting publications on the Ireland forgeries are: *Inquiry into the authenticity of certain Papers, etc., attributed to Shakespeare*, by Edmond Malone (1796); the elder Ireland's *Vindication of his Conduct* (1796); *An Apology for the Believers in the Shakespeare Papers* (1797), and a *Supplemental Apology* (1799), both

by George Chalmers. *Vortigern* was republished in 1832. The elder Ireland's correspondence with regard to the forgeries is preserved in the British Museum, with numerous specimens of his son's talent.

IRELAND, an island to the west of Great Britain, extending from $51^{\circ} 26'$ to $55^{\circ} 21'$ N., and from $5^{\circ} 25'$ to $10^{\circ} 30'$ W. The 100 fathom line lies a short distance beyond its western coast and leaves it in structural affinity with western Europe. The north channel between the Mull of Kintyre (Scotland) and Torr head has a width of only $13\frac{1}{2}$ m.; in the south, St. George's channel has a width of 69 m. between Dublin and Holyhead (Wales), and of 47 m. at its southern extremity; in the centre the Irish sea attains a width of 130 miles. The area is 20,360,601 ac., and the population (1926), 4,229,124.

GEOLOGY

Ireland, rising from shallow seas on the margin of the submarine plateau of western Europe, records in its structure the successive changes that the continent itself has undergone. The first broad view of the country shows us a basin-shaped island consisting of a central limestone plain surrounded by mountains; but the diverse modes of origin of these mountains, and the differences in their trend, suggest at once that they represent successive epochs of disturbance. The north-west highlands of Donegal and the Ox Mountains, with their axes of folding running north-east and south-west, invite comparison with the great chain of Leinster, but also with the Grampians and the backbone of Scandinavia. The ranges from Kerry to Waterford, on the other hand, are clearly parts of an east and west system, the continuation of which may be looked for in South Wales and Belgium. The hills of the north-east are mainly the remnants of lava-plateaux, which carry the mind towards Skye and the volcanic province of the Faeroe Islands. The two most important points of contrast between the geology of Ireland and that of England are, firstly, the great exposure of Carboniferous rocks in Ireland, Mesozoic strata being almost absent; and, secondly, the presence of volcanic rocks in place of the marine Eocene of England.

The fact that no Cambrian strata have been established by palaeontological evidence in the north and west of Ireland has made it equally difficult to establish any pre-Cambrian system. The great difference in character, however, between the Silurian strata at Pomeroy in county Tyrone and the adjacent metamorphic series makes it highly probable that the latter masses are truly pre-Cambrian. The other metamorphic areas of the north and west present even greater difficulties, owing to the absence of any overlying strata older than the Old Red Sandstone. They are generally referred to as "Dalradian," a convenient term invented by Sir A. Geikie for the metamorphic series of the old kingdom of Dalriada. The oldest rocks in this large area are a stratified series of mica-schists, limestones and quartzites, with numerous intrusive sheets of diorite, the whole having been metamorphosed by pressure, with frequent overfolding along axes with a north-easterly or Caledonian trend.

Following on these rocks of unknown but obviously high antiquity, we find fossiliferous Ordovician (Lower Silurian) strata near Killary harbour on the west, graduating upwards into a complete Gotlandian (Upper Silurian) system. Massive conglomerates occur in these series, which are unconformable on the Dalradian rocks of Connemara. In the Wenlock beds of the west of the Dingle promontory there are contemporaneous tuffs and lavas. Here the Ludlow strata are followed in apparent conformity by a thick series of barren beds (the Dingle Beds), which have been variously claimed as Upper Silurian and Lower Devonian. No certain representative of the Dingle Beds has been traced elsewhere throughout the south of Ireland, where the Old Red Sandstone succeeds the uplifted Silurian strata with striking unconformity. The folds which distort these Silurian rocks, including the Dingle Beds, have a north-easterly trend parallel to those which affect strata of the same age in the southern uplands of Scotland and thus belong to the Caledonian system. The best example of these folds is the axis of Leinster, its core being occupied by granite which is now exposed continuously for 70 m., forming a moorland from Dublin to New Ross. On either flank

the Silurian shales, slates and sandstones, which are very rarely fossiliferous, rise with steep dips. They are often contorted, and near the granite pass into mica-schists and quartzites.

In south-eastern Wexford, in northern Wicklow (from Ashford to Bray), and in the promontory of Howth on Dublin Bay, an apparently earlier series of green and red slates and quartzites forms an important feature. The quartzites, like those of the Dalradian series, weather out in cones, such as the two Sugarloaves south of Bray, or in knob-set ridges, such as the crest of Howth or Carrick Mt. in county Wicklow. The radial or fan-shaped markings known as *Oldhamia* were first detected in this series, but are now known from Cambrian beds in other countries; in default of other satisfactory fossils, the series of Bray and Howth has long been held to be Cambrian.

Extensive denudation followed the Caledonian folding and on the land-surface thus formed the Devonian lakes gathered, while the rivers poured into them enormous deposits of sand and conglomerate. Large areas of Old Red Sandstone have been brought up from beneath the denuded Carboniferous along the Hercynian folds of the south. The conglomerates, moreover, appear at intervals through the limestone covering of central Ireland, and usually weather out as conspicuous scarps or "hogs'-backs." The Slieve Bloom mountains are thus formed of a dome of Old Red Sandstone folded on a core of unconformable Silurian strata; while in several cases the domes are worn through, leaving rings of Old Red Sandstone hills, scarping inwards towards broad exposures of Silurian shales. Further north an extensive area of Old Red Sandstone is preserved within the rift valley, which is continued from central Scotland, beneath the North Channel and the basalt plateau, and comes to light again south-west of Lough Neagh. The Old Red Sandstone shows local evidence of contemporaneous volcanic activity.

The highest beds of Old Red Sandstone type pass up conformably in the south of Ireland into the Lower Carboniferous, through the "Yellow Sandstone Series" and the "Coomhola Grits" above it. The Yellow Sandstone contains *Archæonodon*, the oldest known fresh-water mollusc, and plant-remains; the Coomhola Grits are marine, and are sometimes regarded as Carboniferous, sometimes as uppermost Devonian. In the south, the Carboniferous deposits open with the Carboniferous Slate, in the base of which the Coomhola Grits occur. Its lower part represents the Lower Carboniferous Shales and Sandstones of the central and northern areas, while its upper part corresponds with a portion of the Carboniferous Limestone of the central plain.

The Lower Carboniferous Sandstones are conspicuous in the region from Milltown near Inver Bay in southern Donegal to Ballycastle in county Antrim. In the latter place they contain workable coal-seams. The Carboniferous Limestone often contains black flint (chert), and at some horizons conglomerates occur, the pebbles being derived from the pre-existing ridges of the "Caledonian" land. A black and often shaly type called "calp" contains much clay derived from the same land-surface. While the limestone has been mainly worn down to a lowland, it forms fine scarps and tablelands in county Sligo and other western regions. Contemporaneous volcanic action is recorded by tuffs and lavas south-east of Limerick and north of Philipstown. The beds above the limestone are shales and sandstones, the true stratigraphical horizon of which is as yet ill defined, but which certainly range in places into the Middle Coal Measures. No beds equivalent to the Upper Coal Measures of England have yet been proved South of the line between Galway and Dublin the coal is anthracitic, while north of this line it is bituminous.

The "Hercynian" earth-movements, which so profoundly affected north-west and north-central Europe at the close of Carboniferous times, gave rise in the south of Ireland to a series of east and west folds and in the centre to a series of lesser folds deflected along Caledonian trend lines. The uplift which followed upon this folding led as in England to extensive denudation. It is however only in the north-east of Ireland that the subsequent history can be traced. Here the succeeding Permo-Triassic beds lie unconformably across the Carboniferous and older strata.

The Permian sea has left traces at Hollywood on Belfast Lough

and near Stewartstown in county Tyrone. Certain conglomeratic beds on which Armagh is built are also believed to be of Permian age. The Triassic sandstones and marls, with marine Rhaetic beds above, are preserved mainly round the basaltic plateaux of the north-east and extend for some distance into county Down.

The Jurassic system is represented in Ireland by the Lower Lias alone, and it is probable that no marine beds higher than the Upper Lias were deposited during this period. From Permian times onward, in fact, the Irish area lay on the western margin of the epicontinental seas that played so large a part in determining the geology of Europe. Denudation, consequent on the renewed uplift of the country, affected the Jurassic beds until the middle of Cretaceous times. The sea then returned, in the north-east at any rate, and the first Cretaceous deposits indicate the nearness of a shore-line. Dark "green-sands," very rich in glauconite, are followed by yellow sandstones with some flint. These two stages represent the Upper Greensand, or the sandy type of the English Gault. Further sands represent the Cenomanian. The Turonian is also sandy, but in most areas was not deposited, or has been denuded away during a local uplift that preceded Senonian times. Even the succeeding Senonian chalk, where it rests in the extreme north on Trias or even on the schists, is often conglomeratic and glauconitic at the base, the pebbles being derived from the old metamorphic series. This chalk appears to underlie nearly the whole basaltic plateaux, appearing as a fringe round them, and also in an inlier at Templepatrick.

No records of late-glacial submergence such as characterize Scotland and Fennoscandia are known in Ireland. The earliest post-glacial deposits are the submerged forests and the marls at the base of the peat bogs. In Early Neolithic (Campignian) times a slight submergence with a maximum of some 20 ft. affected the north-east of Ireland, and the fauna of the deposits dating from this period shows a temperature several degrees higher than that of the present day. Wide-spread growth of mountain peat has occurred since the bronze age.

After the Irish chalk had been elevated and worn into gently rolling downs, on which flint-gravels gathered, the great epoch of volcanic activity opened, which was destined to change the character of the whole north-west European area. Fissure after fissure, running with remarkable constancy north-west, broke through the region now occupied by the British Isles, and basalt was pressed up along these cracks, forming thousands of dikes, from the coast of Down to the Dalradian ridges of Donegal. One of these on the north side of Lough Erne is 15 m. long. Most of the igneous region became covered with sheets of basaltic lava, which filled up the hollows of the downs, baked the gravels into a layer of red flints, and built up, pile upon pile, the great plateaux of the north. There was little explosive action, and few volcanic vents can now be traced, so that it is thought that the lavas originated in fissure eruptions like those of Iceland. After a time, a quiet interval allowed of the formation of a deep zone of lateritic weathering represented by 50 to 90 ft. of lithomarge capped by pisolitic iron ore and bauxite. The plant-remains associated with these beds form the only clue to the post-Cretaceous period in which the volcanic epoch opened, and they have been placed by Mr. Starkie Gardner in recent years as early Eocene. During this time of comparative rest, rhyolites were extruded locally in county Antrim. A renewal of the basaltic eruptions produced the Upper Series of plateau lavas, beneath which this old subtropical land surface is preserved. There was then a second long period of weathering which produced a soil comparable in thickness with that of the Interbasaltic zone. Warping led to the denudation of this soil, and its concentration in the centre of the basin now occupied by Lough Neagh. Thus were formed the Lough Neagh Clays, the plant remains of which are identical with those of the Interbasaltic Zone, and which must therefore be regarded as also of Eocene age. The whole plateau was subsequently greatly modified by faulting during the diastrophism of the Miocene period, but no further volcanic activity supervened, and no deposits of this period or of the later Pliocene are preserved to us. A well developed peneplain and still later deep cut fjords are all that re-

main as records of the history of Ireland between the end of the Eocene and the beginning of the Glacial periods.

Along the whole south coast of Ireland occurs a preglacial shoreline buried beneath the glacial drifts and lying some 10 ft. above present sea-level. This runs up the sides of the fjords and proves their submergence in preglacial times. Overlying scree deposits from the degradation of the sea-cliff, descend below sea-level and prove emergence before the advent of the land ice.

During the Glacial period Ireland was covered by ice-sheets, which extended from sea to sea and with the exception of some of the higher hills, which no doubt had their own snow-fields there was no actually unglaciated area. The Newer Drift probably does not cover as wide an area as the older, but its limits are not yet known. Boulder clay and glacial gravels cover large regions in the central plain and moraines occur around the mountains. The main centres of snow accumulation lay in the hill areas of the north-west and west but the whole eastern coast was at one time invaded by ice, which came south from Scotland along the basin of the Irish sea and carried with it the highly characteristic riebeckite-eurite of Ailsa Craig in the Firth of Clyde. Wide-spread moraines and esker ridges mark the stages of retreat of the ice, and systems of marginal drainage are developed round the hills.

PHYSICAL GEOGRAPHY

The central plain which reaches the east coast between Dundalk bay and Dublin bay and extends westward to the highlands of Connaught, separates the mountains of the north with their Caledonian trend-lines from the ranges of the south, where remnants of Hercynian folds predominate. The Leinster chain belongs structurally to the north. Lough Neagh occupies a depression in a region of warped basaltic rocks. To the north-east is the Antrim plateau, capped with lava and with no height exceeding 2,000 feet. The Sperrin mountains, to the north-west, attain a height of 2,240 ft. in Sawel mountain, whilst to the south-east several peaks exceed 2,000 ft. in the mountains of Mourne. This rim is pierced by the river Bann, which drains Lough Neagh to the north by the river Lagan, which enters Belfast lough to the east; by tributaries of the Upper Bann and by the river Newry to the south, and to the west by the gap partly occupied by the river Blackwater and the Ulster canal.

The highlands of the rim, favoured by settlers in late Neolithic times, but abandoned for the fertile land which replaced the lowland swamps and forests in later periods, are now given over to pasturage. Villages seek the shelter of the valleys. The shores of Lough Neagh and the valleys of the Bann and the Lagan, sheltered from excessive rains, provide good agricultural land and rich meadows for the fattening of cattle. Corn and root crops, flax and potatoes predominate. The Congested Districts Board from 1891 onwards did a great deal to help the small-holder. Co-operative creameries and agricultural credit societies have also been important economic influences. Coleraine is a small port on the Bann; Ballymena, Antrim and Portadown are market towns with rural industries and secondary railway centres. In the sheltered bays of the north-east coast are fishing villages, frequented by tourists in summer. Larne is a packet station and has aluminium works. Belfast dominates the industrial activity of the region. It has brought to an area rich in flax, and to a people born to the making of linen, coal and iron from Scotland, and thus has made possible the development of large-scale industries. Along Belfast lough are large residential areas.

To the west of the river Foyle are the mountains of Donegal, rising in Mt. Errigal to a height of 2,466 ft., and in Slieve Snaght to 2,240 feet. Blocks of hills running from north-east to south-west, separated and cut across by many deep, narrow valleys,

some of which are occupied by elongated lakes, isolate the coastal lowlands of the north-west, where habitation has persisted at least since the end of Neolithic times. Villages nestle along the creeks. Agriculture is hindered by exposure to strong rain-bearing winds from the west and away from the coast, by the height of the land and by the thin soil. Unification under a central authority has been a difficult process. Settlement has been largely confined to the valley of the Foyle and Donegal bay. Lifford, although but a suburb of Strabane (in Tyrone), acts as the county town of Donegal. Londonderry, near the head of Lough Foyle, is a port with a small ship-building industry.

Beyond Loughs Conn, Mask and Corrib are the ice-worn masses of Mayo and Galway, exceeding 2,000 ft. in height at several points. Submergence and marine erosion help to account for the much-indented and island-studded coast. Agriculture is limited, as along the Donegal coast, and fishing in the sheltered waters is an important occupation. Hardy ponies are reared on the mountains of Connemara. Descendants of early types and groups survive in the hills, and the influence of the organization of the eastern plains has penetrated slowly. Between Galway bay and the mouth of the Shannon is the promontory which comprises Co. Clare. Here the mountains are lower and more rounded, exceeding 1,000 ft. only in a few isolated peaks. The coast is more regular and the percentage of low land is higher. Kilkee, Kilrush and Miltown Malbay are seaside resorts.

To the south of the Shannon estuary lies the remarkable country of Co. Kerry and south-west Co. Cork. Parallel ribs of high land form steep-sided promontories separating the long, narrow rias which characterize this coast. Slieve Mish (Baurtregau, 2,796 ft.), Dingle bay, Macgillycuddy's Reeks (Carrantuohill, 3,414 ft.), Kenmare river, Slieve Miskish and the Caha mountains (Knockowen, 2,169 ft.), Bantry bay, Sheep's head and Dunmanus bay illustrate well the rapid alternation of land form. Isolated groups cling to the narrow shores of the rias and earn a precarious living by fishing and sheep-rearing. Modern communications show the forced seclusion of the area. A line runs from Castlemaine along the south side of Dingle bay. Kenmare, on Kenmare river, and Bantry, at the head of Bantry bay, both have connections with towns to the east, but have not easy communication with one another. A line following a gap to the north-east of Macgillycuddy's Reeks serves Killarney and adjacent places. Castlemaine is in touch with Kenmare.

Between the mountains of the south-west and the Leinster chain lies a region of broken country which deserves special attention. Greatly influenced by Armorican fold movements, the area is composed largely of east to west lines of sandstone hills separated by limestone synclines. A general slope towards the south led to consequent drainage across rocks of varying hardness. "Subsequent" tributaries limited their valleys to the softer limestone and captured the headwaters of many of the "consequent" streams. The present drainage pattern, therefore, presents long east-to-west lines connected by short north-to-south corridors. The sea has invaded the lower reaches of the Bandon, the Lee, the Blackwater and the Suir, and their estuaries provide good harbours. Between the Suir and the Blackwater are the Ballyhouna hills (Glenosheen 1,696 ft.), the Galtee mountains (Galtymore 3,015 ft.) and, slightly to the south of these ranges, the Knockmealdown mountains (2,609 ft.), and the Comeragh mountains (Knockanaffrin 2,478 ft.). The Boggeragh mountains (Musheramore 2,118 ft.), continued by lower ranges to the east, separate the Blackwater from the Lee. Agriculture in the lowlands and sheep-rearing on the hills are the chief occupations in this diversified country. The structural pattern facilitates communication for some distance to the west, and also provides routes to the north. Cork and Waterford are packet stations which have benefited by these advantages, and Cork, on its fine natural harbour with Cobh (Queenstown) on an island, is the effective capital of the south.

Caledonian trend-lines prevail in the Leinster range which, rising steeply to the south of Dublin, runs south-westward and overlooks the lower valley of the Barrow. Several heights exceed 2,000 ft. and Mt. Lugnaquilla reaches 3,039 feet. Rain-soaked basins favour the formation of peat bogs, and give rise to slug-

gish streams which later cut rocky gorges down the steep sides. The windward slopes of the west are less steep than the eastern edge, and provide good pasturage. The coastal plain facing the Irish sea is sheltered from excessive rains, but is too narrow to be employed extensively for agriculture. It widens considerably, however, to the south, where the foothills of the Wicklow mass die away; arable land is estimated at 33% in Co. Wexford, whereas it only comprises 18% of Co. Wicklow. The Wicklow valleys were once exploited for their gold.

The Central Plain.—Enclosed by this girdle of highlands lies the central plain, consisting largely of limestone and covered, particularly towards the east, by drifts of sands and gravels deposited during the retreat of the ice-sheets. Between the Shannon and Loughs Mask and Corrib are extensive exposures of limestone, providing, in a region of abundant rainfall, good pasturage for cattle. Rising at the foot of Cuilcagh mountain, the Shannon flows in a general southerly and south-westerly direction. It winds through a marshy, rain-soaked area, and swells out into many broad, shallow lakes (Lough Ree, Lough Derg). At Killaloe, on the southern extremity of Lough Derg, it has a gorge between Slieve Bernagh and the Arra mountains, and from this point to Limerick, at the head of its estuary, its flow is more rapid. In this section it is proposed (1928) to harness the Shannon for the generating of electricity. (*See SHANNON.*) The Siemens-Schücker scheme aims at keeping the waters of Lough Derg at winter level, and diverting the river via O'Briensbridge to the generating station at Ardnacrusha, where the river will return to its natural course. It was anticipated that the Leinster circuit would be completed and served during 1929. Later, it is planned to erect further works at the outlet of Lough Ree. Overhead cables have been erected (1928) to Dublin, to various parts of Leinster, to Waterford and to Cork.

The marshy line of the Shannon has long been a barrier to communication. Athlone developed as a ford town where firm land approached the river banks, and has continued as a railway centre. Banagher and Shannon Bridge functioned similarly, but have lost much of their importance in recent times. To the east of the Shannon is an area of limestone and boulder clay studded with shallow lakes and peat-bogs. It has provided many obstacles to movement and settlement throughout history, and despite natural desiccation and drainage many of its disadvantages continue. Early roads follow the dry ridges of the eskers above the marsh, and one starting from Tyrrellspass undoubtedly added greatly to the early importance of Athlone. The wet lowlands of Meath, Westmeath, Kildare and Dublin provide pasture.

The extension of the plain to the eastern coast between Dundalk and Dublin provided one of the historic entries into Ireland. Control of this coastal strip has always been recognized as of great strategic importance, and Dublin (*q.v.*), in which this power has been vested, has developed as the administrative centre of central and southern Ireland. The Royal canal and the Grand canal connect it with the Shannon, and a branch from the latter links it with Waterford and the river Suir. The Great Northern railway runs northwards along the coast to Drogheda and Dundalk, and lines of the Great Southern system run westward and southward. Kingstown is a packet station in communication with Holyhead, Wales. Dublin imports sugar, grain, timber and general merchandise, and exports grain, whisky, beer and linen, but its function as a government centre is most important.

Climate.—Its girdle of high land and its insular position in the track of south-westerly winds are factors governing the climate of Ireland. The south-western and western coasts are comparatively warm in winter, Valencia having a January temperature of 44.6°. Numerous inlets increase the maritime influence. The central plain and the east coast, in the lee of the mountains, are more continental. Birr has a January temperature of 39.7°, and Dublin one of 41.7° F. Maritime influences delay the summer maximum temperatures in the south-west. Valencia records 59° in July and 59.3° in August, the corresponding figures for Birr and Dublin being 59.1° and 58.6° and 60.5° and 59.7° respectively. The autumn temperatures also are much more evenly graded in the west than in the centre and east. The distribution

of rainfall may be closely correlated with the orographical features. The heaviest falls occur on the mountains of Galway and Kerry, where considerable areas receive over 80 inches. Most of the mountainous areas around the coasts receive over 40 in., but averages for various localities on the central plain run between 30 in. and 40 in., whilst the east coast around Dublin receives under 30 inches. Maximum rainfall occurs at Valencia in winter (October and November 5.5 in., December 6.5 in., and January 5.6 in.); but the fall is steady throughout the year, May, the driest month, recording 3.1 inches. The mean annual rainfall at this station is 56.0 inches. Dublin (mean annual rainfall 27.7 in.) has its maximum in late summer and in autumn. The average fall in August is 3.1 in. and in October 2.9 in.; February, with 1.9 in., is the driest month.

Flora and Fauna.—Insularity retarded the recovery of Ireland's flora and fauna after the Ice age. Whereas Germany has 90 species of land mammals, Britain has 40 and Ireland 22. In western Ireland are some plant species, including members of the heath family, not found in other parts of the island. South-eastern Ireland has many species in common with south-west England. A few plants are found only in Ireland and America, and have been classed as an American group. Similar distributions can be traced in the fauna. Some fresh-water sponges in western Ireland are connected with American types. The arbutus, or strawberry tree, is now confined to the south-west corner of Ireland and to the Mediterranean. This is one illustration of a Lusitanian element in the flora, probably persisting from a time before Ireland was separated from Europe, and when an Atlantic coastal flora lived along the shores of the ocean from the Iberian peninsula to Ireland. There are also connections with the north, the mountain or Arctic hare being common to Ireland and Scotland. Remains of reindeer, Arctic fox, and Arctic lemming are found in Irish caves.

People and Settlement.—The retreat of the ice sheets left the central plain a marshy waste, with thick forest growth on drier patches. The moorlands and some coastal strips alone seem to have remained to early man. A limestone shore, rich in flints, and protected from excessive erosion by a capping of basalt, favoured early settlement in Antrim and Down. At Larne flints showing human workmanship have been found, with sea-shells, at from 20 to 25 ft. above the present sea-level. Similar evidence has been obtained from other sites in the north-east and in the south. The arrival of new peoples from the south-west marks the closing phase of the Neolithic period.

With these newcomers are associated large stone monuments, the distribution of which may help to define the chief centres of population at that time. Dolmens, generally consisting of several upright stones capped by large stone slabs, occur frequently in western Ireland. The eastern half of Co. Clare, the upper basin of the Lee in the south-west, and the shores of Donegal bay and Lough Swilly in the north-west, appear to have been important centres. At Carrowmore, in Co. Sligo, occurs a group of 65 dolmens. In the north-east, the numbers decrease from the coasts towards the interior, but no district here appears to have had the importance of the centres already mentioned. In the east, a few occur to the south of Dublin.

Rich deposits of copper in the counties of Wicklow, Waterford, Cork and Kerry added greatly to the importance of Ireland in the Bronze age; southern Wicklow was also rich in gold. Thus the coasts retained their importance, and the lowlands of the interior were still avoided. The finding of gold lunulae of Irish origin in western France, southern Scotland and central Europe suggests that there was commercial intercourse with the Baltic as well as with south-west Europe. The chambered tumulus of New Grange, near Drogheda, with its fine corbelled roof, resembles Maes Howe in Orkney, as well as graves in Brittany and the south of the Iberian peninsula. Many amber beads of Baltic origin have been found in Ireland, whilst the distribution of objects showing a spiral ornamentation has also been cited by some as evidence of contacts with the Baltic, and by others as evidence of southern links. Types of copper weapons and some contemporary pottery are related to Iberian types.

The very early peoples were, no doubt, long-headed (dolichocephalic) and dark and of short stature, resembling the people who inhabited Britain at the same period. Dark, strongly-built, broad-headed men have been located on coastal patches in Wales, Cornwall, Brittany, Spain and southern France, and it has been suggested that they may indicate an anthropological type which spread around the western coast of Europe during the period of commercial expansion in the Bronze age. These elements have been noted in the people around the coasts of Co. Wicklow, and with further investigations may be found in other parts of Ireland. The Rhenish beaker-peoples who are thought to have introduced a broad-headed element into Britain, seem to have had little influence in Ireland. Specimens of the pottery associated with them have been found only at Moytura, Co. Sligo, and at Mount Stewart, Co. Down, and they may be otherwise interpreted. We cannot estimate what may have been the effects on the population of contacts with the Baltic in the Megalithic and Early Bronze period. In the Early Iron age intruders from the Continent gained a footing.

Scandinavian Raiders.—Ireland, untouched by Roman organization, fell a prey to Scandinavian raiders. Norsemen, followed by Danes, raided the coasts and penetrated along the rivers. At the beginning of the 9th century they ascended the Shannon, and later had strongholds around the shores of Lough Ree. Another group progressed along the river Bann and established themselves around Lough Neagh, whence they devastated the neighbouring territory. About the middle of the 9th century Dublin, Limerick and Cork were founded. All three are at the head of estuaries and command good water-ways into the interior. The end of the 10th century and the beginning of the 11th saw a revival of the native tribes, which culminated in the overthrow of the Norse forces by the men of Munster and Connaught at the battle of Clontarf in 1014. During their régime the value of the coast lands and the valley-ways for settlement had again been accentuated. They doubtless strengthened the fair, long-headed element in the population, and their raids tended to drive the darker elements to the shelter of the hills.

The Anglo-Norman invasion accentuated divisions of long standing in Ireland. Strongbow landed near Wexford in 1169, and took advantage of inter-tribal struggles to extend his own power. Later, the Anglo-Normans obtained a firm hold around the coasts and gradually took possession of the fertile lowlands. The mountains became more and more the strongholds of the Irish, whence they periodically raided the intruders on the plain. In the reign of James I. an attempt to make the English land system universal aroused the chiefs of the north-west and north-east to revolt. They were defeated and their land confiscated. English and Scottish colonists received grants in Tyrone, Donegal, Armagh, Cavan, Fermanagh and Derry. The citizens of London were granted the site of Derry, which they garrisoned and fortified, Londonderry becoming the stronghold of the new settlers. In the time of Cromwell, a ruthless policy of extermination was followed, and the native peoples beyond the Shannon were evicted from their holdings. The land was parcelled out among adventurers; many of the original holders remained as serfs, others preferred a precarious independence in the mountains.

The potato, introduced early in the 17th century, provided a large crop which needed little attention and encouraged a rapid increase of population. In 1845 its dependents numbered over 8,000,000; then came the terrible famine of 1846-48, from which the country has not yet recovered. In 1851 the population had fallen to 6,500,000 and, as a result of wholesale emigration, largely to the United States of America, the figure continued to fall. Between 1847 and 1852 over 1,200,000 people emigrated, and of these more than 1,000,000 went to the United States of America. Between 1851 and 1905 over 4,000,000 left the country. The loss of population was borne chiefly by the agricultural districts. In 1841 the rural population was returned as 7,052,923, and the urban as 1,143,674, while the corresponding figures in 1901 were respectively 3,073,846 and 1,384,929. The increase in the urban population has been accentuated by the development of certain large centres. The population of Belfast was, in 1891,

273,079; in 1901, 349,180; and, in 1926, 415,007; the corresponding figures for Dublin are 268,587; 289,108, and 316,471.

The areas and populations of the counties and county-boroughs of Northern Ireland were estimated in 1926 as follows:—

Counties and county boroughs	Area in statute acres (exclusive of water)	Males	Females	Total
Antrim	702,850	92,600	99,018	191,618
Armagh	312,772	53,635	56,448	110,083
Belfast C.B.	14,797	195,588	219,419	415,007
Down	608,859	101,238	107,941	209,179
Fermanagh	417,912	30,094	27,891	57,985
Londonderry	512,495	47,127	47,384	94,511
Londonderry C.B.	2,198	20,783	24,381	45,164

For the Irish Free State the figures are:—

Counties and county boroughs	Area in statute acres*	Population in 1926		
		Males	Females	Total
<i>Province of Leinster:</i>				
Carlow	221,485	17,802	16,702	34,504
Dublin County	218,873	87,378	101,870	189,248
Dublin C.B.	7,911	151,739	164,732	316,471
Kildare	418,645	31,982	26,053	58,035
Kilkenny	509,457	37,033	33,932	70,965
Leix (Queen's)	424,838	27,205	24,344	51,549
Longford	257,770	20,804	19,027	39,831
Louth	202,181	31,668	31,019	62,687
Meath	577,735	33,005	29,904	62,909
Offaly (King's)	493,263	27,499	25,022	52,521
Westmeath	434,665	30,114	26,682	56,796
Wexford	580,950	48,561	47,251	95,812
Wicklow	499,958	28,903	28,680	57,583
Total of Leinster	4,847,731	573,693	575,218	1,148,911
<i>Province of Munster:</i>				
Clare	788,337	50,064	44,964	95,028
Cork County	1,841,035	145,853	141,401	287,254
Cork C.B.	2,681	37,306	41,162	78,468
Kerry	1,161,752	77,589	73,276	150,865
Limerick County	661,573	51,656	48,588	100,244
Limerick C.B.	2,386	19,329	20,361	39,690
Tipperary	1,051,304	72,867	68,079	140,946
Waterford County	453,051	26,755	25,137	51,892
Waterford C.B.	1,438	12,645	14,001	26,646
Total of Munster	5,063,557	494,064	476,969	971,033
<i>Province of Ulster (part of):</i>				
Cavan	467,025	43,485	38,962	82,447
Donegal	1,193,641	78,060	74,451	152,511
Monaghan	318,990	33,240	31,993	65,233
Total of Ulster (part of)	1,979,656	154,785	145,316	300,101
<i>Province of Connaught:</i>				
Galway	1,467,850	88,462	80,849	169,311
Leitrim	376,510	29,232	26,656	55,888
Mayo	1,333,356	86,749	85,912	172,661
Roscommon	608,290	43,283	40,221	83,504
Sligo	442,205	36,648	34,745	71,393
Total of Connaught	4,228,211	284,374	268,383	552,757
Total of Free State	17,019,155	1,506,916	1,465,886	2,972,802

*Exclusive of larger rivers, lakes and tideways.

Vital Statistics. Northern Ireland.—The following table gives the number of marriages, births and deaths for four years:—

Year	Marriages	Births	Deaths
1923	7,974	30,097	18,790
1924	7,514	28,496	20,299
1925	7,682	27,686	19,784
1926	7,228	28,162	18,827

The number of births per 1,000 of the population in 1926 was 22.42, and the number of deaths per 1,000 of the population 15.82. The high birth rate, a considerable fall in the emigration figures, and industrial developments are important factors in the maintenance of the population.

Irish Free State.—The number of marriages, births and deaths for four years are given in the following table:—

Year	Marriages	Births	Deaths
1923	15,632	61,690	42,217
1924	14,822	63,402	45,180
1925	13,820	62,069	43,650
1926	13,570	61,176	41,740

The number of births per 1,000 of the population in 1926 was 20.58, and the number of deaths per 1,000 of the population was 14.04. In 1924 the corresponding figures were 20.06 and 14.29. In England and Wales the birth rate has fallen from 25.5 in 1920 to 16.6 in 1927. This fact makes the Irish figures stand out as particularly high.

Religions.—(See IRELAND: *Mediaeval History*, and IRELAND, CHURCH OF.) In Northern Ireland, the principal religious professions, as recorded at the census of 1911, were: Roman Catholics, 430,161; Protestant Episcopalians, 327,076; Presbyterians, 395,039; Methodists, 45,942; others, 52,313; giving a total of 1,250,531. For the Irish Free State, the figures (1911) were: Roman Catholics, 2,812,509; Protestant Episcopalians, 249,535; Presbyterians, 45,486; Methodists, 16,440; others, 15,718. The Roman Catholic Church is governed in Ireland by four archbishops, whose sees are in Armagh, Dublin, Cashel and Tuam, and by 23 bishops. The Presbyterian Church, whose adherents are found principally in Ulster and are largely the descendants of Scottish settlers, was originally formed in the middle of the 17th century, and in 1840 a reunion took place of the two divisions into which the Church had separated. The Methodist Church in Ireland was formed in 1878 by the union of the Wesleyans with the Primitive Methodists. (O. J. R. H.; X.)

AGRICULTURAL CO-OPERATION

The main interest and importance of the co-operative movement in Ireland since the beginning of the World War consists in the struggle of its promoters to preserve and develop it as the chief agency for implementing a certain philosophy of rural life and evolving an agricultural policy consonant therewith. The movement had been initiated a quarter of a century before the War by men who were not themselves farmers, and its inspiration has ever since come from practical idealists. These men realized that in a country dependent upon a sound agricultural economy for the well-being of every section of the population, a technically educated and efficiently organized rural community was of the first importance.

In countries highly industrialized, agriculture could be neglected without disaster; in a country predominantly agricultural the efficient production and economical distribution of food was what mattered most. Yet those who saw that these ends could best be obtained by the application of the co-operative principle and system to the occupation of farming were chiefly concerned for the building of a rural civilization which would provide intellectual interests and social amenities calculated to counteract "the lure of the city." For the solution of the modern rural problem as they saw it, they invented the formula: "Better Farming, Better Business, Better Living." To use a New World phrase, the "pivotal" thing was Better Business and Better Business was co-operation.

Agricultural Organization Society.—The post-war civil disturbances in Ireland might well have wrecked the movement. War prices and a demand which ignored quality had considerably demoralized the dairy societies. The movement was in no condition to meet the sudden decline in prices which set in in 1920-21. It became clear that its future success—perhaps even its survival—would depend upon the ability of the Irish Agricultural Organization Society to continue its service as guide, philosopher and friend of the societies. This central body had always derived from

the farmers it served and from philanthropic individuals a large part of its funds. In the circumstances of the country, these subscriptions were bound to fall off. While the Development Commission, which was authorized by its act to treat "the organization of co-operation" as one of the ways of "aiding and developing agriculture," functioned in Ireland it subsidized the I.A.O.S. for this purpose. Under the Anglo-Irish Treaty, the Commission transferred its functions and a proper proportion of its funds to the two Irish Governments. The I.A.O.S. had to be partitioned, an Ulster A.O.S. being formed to operate in the six north-eastern counties.

The Government of the Irish Free State has from year to year continued the grants to the I.A.O.S. and for its first year the Government of Northern Ireland continued it to that part of the organization movement which came within its territory. This, however, was not renewed, except for a grant of £200 in 1927, increased to £700 in 1928, and in Northern Ireland the movement consequently had greatly to restrict its work. But that the farmers there have come to realize its value is evident from the fact that most of its funds come from the societies' contributions and the movement is thus able, through its own practical public spirit, supplemented by that of a few friends, to carry on without incurring a deficit.

The new Free State Government, from the start, made every effort to reconstitute the agricultural policy of the country. This was to be expected in a land which, itself purely agricultural, had just obtained independence from a union of countries mainly industrial. The department was merged in a new Ministry of Lands and Agriculture, and a commission on Agriculture was set up which made many far-reaching recommendations, especially emphasizing the importance of agricultural education and commending the development of co-operation as well as an increased subvention to the I.A.O.S. A grant of £10,000 was voted by Dail Eireann for the year 1926-27, and £8,500 p.a. for the four following years.

Position of the Societies.—A movement, started in the autumn of 1926, to market the butter of the co-operative creameries in common, under a new trade organization (Irish Associated Creameries, Ltd.) proceeds *pari passu* with the decision of the State to enable bodies of farmers (organized into registered co-operative societies by the I.A.O.S.) to take over, by the utilization of Government credit, the machinery, buildings and trading interests of the principal creamery proprietors in Southern Ireland. A "holding body," consisting of civil servants, has been registered under the Industrial and Provident Societies Act to serve as a temporary "bridge" between existing proprietors willing to sell and prospective co-operative farmers organizing to purchase. More than three-fourths of the existing co-operative dairying societies have already voluntarily signed agreements to market their butter through Irish Associated Creameries Ltd., and it is anticipated that, with the additional trade passing into co-operative hands through the scheme for purchasing new premises and plant, and acquiring existing business, the creamery industry of the Irish Free State will be virtually run for the future by and in the interests of the organized dairy farmers. In Irish Co-operative Meat Ltd. (Waterford), another co-operative enterprise has been successfully launched and, while the promoters in its earlier years are pursuing a cautious policy, it is hoped that a considerable part of the pig and cattle business of the principal counties in Munster and Southern Leinster will be placed on a sound basis whether the animals are marketed as live stock or dead meat, and a number of subsidiary industries developed through the utilization of by-products.

Credit societies have largely developed in recent years. The Commission on Agriculture had recommended that this aspect of co-operative business be specially endowed; and in 1925 the Dail, at the instance of the Minister for Agriculture, passed a vote for loans not to exceed £100,000, for restocking of lands, to be advanced to credit societies approved by the I.A.O.S., to whom the administration of the scheme was entrusted. The Agricultural Credit Act 1927 also makes provision for similar loans and for loans to co-operative societies of agricultural producers. Thus

were re-established satisfactory relations between the State aid and the self-help parts of a movement which may encourage other countries to adopt the device of an "organization society," working in close co-ordination with the governmental Departments of Agriculture.

The organization of about 150,000 farmers, mostly heads of families and, therefore, representing over 600,000 persons (in a country containing about 4,250,000 people), into a movement whose aggregate business for the decade 1914-23 (inclusive) was well over £80,000,000—to which creameries contributed about one-half—is not an unimportant factor in Irish economics.

Education.—The need of all co-operative movements is always education, and the higher the development the greater is that need. The hampered condition of the Central Organization society is probably the true cause of the halt of the movement as a whole. Up to the present, the I.A.O.S. has had to render many services, notably technical advice to creameries and other societies, which the Government, through the Ministry, are now rendering under the Dairy Produce Act and the Agricultural Produce (Eggs) Act. To ensure the future of co-operation, technical instruction in itself is not the chief desideratum. When it can leave that to the Ministry, the Organization society will concentrate on educating the farmers not only in credit and the technique of co-operation, but in the co-operative spirit.

The Government of Northern Ireland, like that of the Free State through its Department of Agriculture, enforces egg-grading; but the Ulster Organization society, with its small staff, cannot do the work necessary to educate the farmer up to a standard which the Government can only punish him for failing to reach. The work, therefore, cannot be expected to show immediate spectacular results, but that, it must be understood, is as much due to the width of the aim as to the narrowness of the resources. And these two have another connection. To-day the central society's funds are largely drawn from the fees the farmers will willingly pay it for technical instruction, which is not a co-operative but a manufacturing technique. When that function is transferred to Government and the Organization society is restricted to its educational but less remunerative purposes, the farmers' financial support will for some time be considerably lessened.

Nevertheless, the founders of the movement were convinced that nothing less than a continual extension of the study of the rural problem—the regarding of agriculture as an *industry*, as a *business* and as a *life*—could bring the country population to a standard of efficiency demanded by modern economic conditions. The next step, therefore, in this concerted advance was to gather and distribute knowledge of every side of agricultural co-operative evolution the world over, and to provide a centre at which students and organizers could study and compare the progress of local developments. To provide this, the Co-operative Reference library had been founded in Dublin in 1913. One of the founders of the Irish movement has endowed a trust (which the trustees christened the Horace Plunkett Foundation) for the purpose of extending the Irish philosophy of rural life throughout the British Commonwealth.

Under its auspices there was convened at Wembley in July 1924 a conference on agricultural co-operation in the British empire. The delegates, who were thoroughly representative of agriculture in this vast area, approved the Irish policy, and called upon the Foundation to establish an office in London to act as a clearing-house for the exchange of experiences and opinions of all organizations which were putting the co-operative principle into practice. This has been begun by opening a London centre which, when the Carnegie United Kingdom Trust promised to defray the cost of maintenance, naturally offered hospitality to the Co-operative Reference Library, an offer which the Carnegie United Kingdom Trust approved. Thus the Foundation is in a favourable position to see that Ireland is kept fully informed of the progress of similar movements in other countries.

HISTORY

Earliest Inhabitants.—The earliest known remains of human habitation in Ireland are assigned by archaeologists to the period of the transition between the early and the late stone age. This period, it is held, was preceded by intense glacial conditions, covering the whole island and extending also over Britain as far south as the estuaries of the Severn and the Thames. The Neolithic and Copper periods which follow are well represented in Ireland, but their data belong rather to archaeology than to history. The bronze age in Ireland, though it has no documents, native or extraneous, has left evidences sufficiently abundant and vivid to be considered historical. To it belong numerous tombs of massive structure, surmounted by great tumuli of earth or stones, the stone slabs in some of them being carved with a great variety of designs, symbolic or ornamental—evidence of a settled population under opulent rulers. Bronze was abundant. There were rich copper mines, but no tin mines, and the tin which was needed to make bronze must have been an article of import, no doubt from Cornwall, during the whole of the bronze age and later. The distinctive feature of this period in Ireland was the production of native gold, of which it is certain that there were comparatively rich deposits in the Wicklow mountain region. Irish gold ornaments of the bronze age have been found in various parts of Britain, in northern France, in Luxembourg, Hanover and Denmark. In Ireland, the principal finds have been in districts far away from the gold-producing region. Finds of the ancient apparatus of bronze-founding are likewise recorded in places far away from copper mines and from seaports through which tin could be obtained. The facts point to a development of commerce, internal and external.

To the Celts of Gaul, and through them to the Greeks, the ancient inhabitants of Britain and Ireland appear to have been known by the common name of Pretani. The two islands, Albion and Iverna, are called in Greek the Pretanic islands. In Latin and first, so far as is known, by Julius Caesar, the name *Brittani* (becoming later *Britanni* and *Brittones*) is substituted for *Pretani* and used distinctively of the people of the larger island, to which the name *Brittania* (Britannia) was given. *Pretani*, represented in early Irish by *Cruithin*, was the name of the people who in later times are known as *Picti*, Picts. Hence it may be inferred that during the bronze age the Picts were the chief people of Ireland as well as of Britain, and this inference is amply confirmed by ancient Irish traditions.

Celtic Colonization.—The earliest Celtic migrations to Ireland cannot be dated earlier than 400 B.C. The Celts were a people of Nordic type, fair haired and tall, physically akin to the Germanic peoples, and speaking a language closely related to the Germanic and Italic languages. At the time of their first immigration, they were in what is known as the "La Tène" stage of material culture. By them iron was introduced into general use in Ireland. They are likely to have arrived in small colonies, settling first in maritime districts and along the larger rivers. The later Celto-Germanic or Belgic migratory movement also extended to Ireland. Ptolemy, about A.D. 150, shows the Manapii and the Cauci settled on the eastern coast, and these are to be identified with the Menapii, a Belgic people, and the Chauci, a Germanic people, on the coast of the North Sea. This later phase of immigration is reflected in various ancient Irish traditions.

The Early Celtic Régime.—The Celts established small states, the nucleus of each state (*tuath*) being a convenient place of assembly to which the freemen could resort, like country people to a local market, without having to lodge away from home. The chief who presided over such an assembly was entitled king.

He also performed the functions of judge and leader in war. Besides the common assembly of freemen (*oinach*), there was a curia or senate (*aireacht*) of nobles, which met in the king's house. The nobles who composed it were known as the companions (*celi*) of the king—we may compare them with the king's *hetairoi* in Homer. In ancient theory, a *tuath* provided an armed levy of 3,000 men, but in the period of contemporary documents much smaller states are indicated. Each *tuath* formed a separate jurisdiction. A freeman was a citizen (*urrad*) in his own *tuath*, but a non-citizen (*deorad*) in any other *tuath*, having, however, a legal status which did not belong to a foreigner (*allmurach*, *muirchúirthe*). Common jurisdiction (*cairde*) for legal proceedings could be made operative by agreement between states. It was the tendency of these small states to group together under hegemonies, the king of one state of the group having a certain authority over the kings of the other states. Such groupings could become permanent. The chief salient feature of the early Celtic régime is the division into five major groups of states, "the Five Fifths of Ireland," so firmly fixed in tradition that in later times, when the country was divided into four "provinces," these were called and are called at present by the Irish word meaning "fifths." The five fifths were:—

Ulster (*Coiced Uloth*, "the fifth of the Uluti"), extending on the west as far south as Loch Bodeg on the Shannon, on the east as far south as Drogheda; much larger thus than the later province. Its capital, *i.e.*, the seat of the chief king, was Emain, "the Navan," close to the city of Armagh.

North Leinster (*Coiced Lagan Tuad-Gabair*, "the fifth of the Lageni north of Gabair"). Capital: Temuir, "Tara."

South Leinster (*Coiced Lagan Des-Gabair*, "the fifth of the Lageni south of Gabair"). Capital: Dinn Rig, on the Barrow.

Munster (*Coiced Muman*, "the fifth of Muma") nearly co-extensive with the counties of Limerick, Cork and Kerry, with part of Waterford. Capital: Temuir Erann, near Ardpatrik, Co. Limerick.

Connacht (*Coiced Connacht*, "the fifth of the Connachta"), including the present Clare but not extending east of the Shannon. Capital: Cruachain, "Rathcroghan" in Co. Roscommon.

Social Order.—The population consisted of free, unfree and slaves. The freemen in the main were the freeholders of land, but their franchise extended also to the men of certain professions and skilled crafts. In the early Christian period, all ecclesiastics and all who received education in the schools of Latin were free. From this and from Caesar's statement of the immunities of the Gallic Druids and their pupils, it may be inferred that the Irish Druids and their pupils were freemen. The unfree were tenants of land, labourers and craftsmen of inferior kinds. Among the landed freemen, the nobles were distinguished by a higher measure of wealth and by having a sufficient number of clients (*celi*, "companions"). The nexus between chief and client was formed by a personal contract which was terminable by either and was terminated by the death of either, differing thus from the hereditary connection of feudal lord and vassal. The clients were freeholders and retained their ownership of land. The chief advanced capital, usually in the form of cattle, to the client, protected his interests in court or assembly, was his leader in war. The client repaid the capital with large interest, attended on the chief at the assembly, and followed him to war, supplied him with labourers for certain works, and rendered him certain reliefs and fixed dues of hospitality. There were two classes of clients, free (*soercheli*) and subject (*doercheli*). A subject client received from the chief, in addition to an advance of capital, his own "honour-price," that is, the legal valuation of his franchise or status, and so ceased temporarily to be a freeman; he paid a tribute in meat, vegetables and malt for the support of the chief's house.

Normally, each freeman was a member of a *fine* or joint family, consisting of descendants of the same great-grandfather—in other words, extending to second cousins. For some purposes, a wider extension of the joint family, as far as fourth cousins, was recognized. If a man died without issue, his property was divided in regulated shares among the members of his *fine*. In case of homicide, the compensation fixed by law was divided in like manner.

A *fine* could be made liable for the undischarged liabilities of any of its members. When a kingship became vacant, any man whose father, grandfather or great-grandfather had been king was eligible to succeed. The power of election belonged to the freemen in assembly, but it seems to have been usual for them to accept a choice made first by a meeting of the nobles.

The Druids.—Druidism, known only in Transalpine Gaul, Britain and Ireland, but not recorded in Britain outside of Anglesea

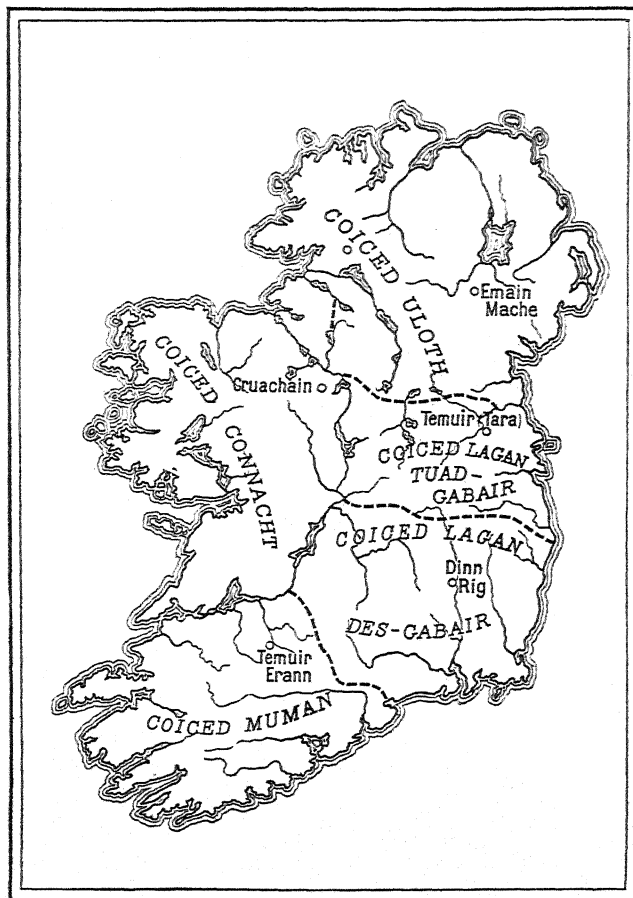

FIG. 1.—ANCIENT IRISH HISTORY. THE "FIVE FIFTHS" OF IRELAND ABOUT THE BEGINNING OF THE CHRISTIAN ERA

Ancient Ireland was divided into fifths, each ruled by its own king; Coiced Uloth (Ulster), with Emain Macha as capital; Coiced Connacht (Connaught), with Cruachain as capital; Coiced Lagan Tuad-Gabair (North Leinster), with Temuir (Tara) as capital; Coiced Lagan Des-Gabair (South Leinster), with Dinn Ríg; and Coiced Muman (Munster), with Temuir Erann as capital

and the northern Pictland, is likely to have originated in Ireland. Pokorny's view seems reasonable and is supported by Irish tradition—that among the pre-Celtic inhabitants there existed a class of seers and sorcerers from which, under the Celtic régime, the Druids were developed. The Druids may be described as an association of professional wise men, philosophers in the early Greek sense, claiming to be experts in all the higher branches of knowledge. They professed special knowledge of the gods, the other world, the future life, the form and measurement of the earth, the movements of the heavenly bodies, the history of men; and they were accepted as authorities in matters of religion and law. They also claimed occult and prophetic powers. In the Roman world, after their suppression by the State, and in Ireland, after its conversion to Christianity, they were chiefly remembered as prophets and magicians. The notion that they were the priests of a particular religion is of modern growth. In Christian Ireland the Druids continued to exist, but with a change of name and with limited scope. They were called *filid*, a name which in time became restricted to the meaning of "poets" but which originally, signifying "seers," denoted one of the functions of the Druids. They no longer had authority in matters of religion but they long continued to practise occult rites of divination. In matters of

learning they were displaced from the ground covered by the Latin teaching of the ecclesiastical schools. They remained the authoritative exponents of the national history, literature and law. In Gaul, notwithstanding the division of the country into so many independent states, the Druids formed a single society, with annual conventions and an elected president. In Ireland, the *filid* do not present this organized form, but they maintain an effective unity through a long course of centuries. They provide a single code of law for the whole country. They follow a common literary usage in writing, and in minutely regulated rules of prosody which they all accept. What Caesar tells of the long course of education of the Gallic Druids and of the instruction given orally and in verse is paralleled in the *filid*. Like the Druids, they enjoy civil immunities. Their persons are sacred. The influence of Druidism remains operative and distinctive in Irish history throughout mediaeval times. It can be traced in the conversion of the Irish to Christianity, in the development of the monastic schools, in Irish law, in the form and content of Irish literature, in lasting pedantic tendencies, but chiefly in a sense of national unity not dependent on political coherence.

Origin of the Monarchy.—The sagas of the "Ulster Cycle" point to a rivalry for the hegemony of Ireland between the Ulster and the Connacht kings. In time the Connacht dynasty gains ground. Its kings cross the Shannon and occupy Uisnech, dominating the fertile midland plain, probably in the 2nd century. In the 3rd century they annex the Boyne valley and make Tara their capital. These conquests break up the pentarchy and give a decided headship to the kings of Tara. Of them the most celebrated in tradition is Cormac, perhaps the first clearly historical personal figure in Irish history, reigning between the years 250 and 300. About this time, taking advantage of the disorder of the Roman empire, the Irish undertake plundering incursions into Roman Britain. A panegyric of the emperor Constantius in 290 speaks of the Britons already "accustomed" to Irish raids. Contact with the Roman military power has effects in Ireland. In imitation of the Roman walls in northern Britain, the Ulster kings protect their diminished territory by a massive earthwork, of which the remains are traced extending, with intervals of lake and forest, across the island from Dundalk bay to Donegal bay. A great quadrangular earthwork called the Dorsey, anciently *Doirse Emna*, "the Gates of Emain," built no doubt in imitation of a Roman legionary camp, guarded the main road leading from Tara to the Ulster capital. The Roman military organization seems to have led to the formation of the *Fiana*, permanent bodies of professional soldiers, peculiar in Ireland to this period. In the earlier heroic tradition there is no military organization. Later, the Irish law does not recognize at all the military profession, and no permanently formed Irish military forces are seen until the introduction of the "galloglasses" from western Scotland in the 13th century. About A.D. 350, the Connacht-Tara dynasty captured Emain and annexed the greater part of Ulster. It reached the height of its power under Niall of the Nine Hostages at the beginning of the 5th century. His sons took possession of the western part of Ulster, and their kindred now ruled all the northern half of Ireland except the eastern strip from the mouth of the Bann to the mouth of the Boyne. The chief kings of this kindred Dall Cuinn, were recognized as kings of Ireland until 1002.

The high-kingship or monarchy was an acknowledged primacy, symbolic of the sense of national unity, rather than a politically operative institution. Its powers are nowhere found defined. It claimed no tributes from the suffragan kings except from the kings of Leinster, who denied the legality of the claim and yielded the tribute only to superior force. The assembly over which the high-kings presided was held annually at Tailte, in the Boyne valley, and was regarded in a sense as national, but there is no instance recorded of its acting as legislative or administrative authority for all Ireland, in the manner in which the assembly of Carman, for example, acted for all Leinster.

In Munster, the 4th century sees the rise of a strong dynasty, of the Eoganacht sept, whose traditions indicate a relatively late immigration from Gaul. Under its rule, the bounds of the older fifth are pushed out and reach in the 5th century an extent

approximately the same as the modern province of Munster.

From the 5th century onward, the five major kingdoms of earlier tradition are replaced by seven. Of these, the older Ulster forms three, the kingdom of Ailech on the west, the kingdom of Airgialla ("Oriel") in the middle, the kingdom of the Ulaid ("Ulidia" or "Ultonia") on the east. The others are Connacht and Munster, both nearly co-extensive with the modern provinces, Mide ("Midia," "Meath"), comprising the greater part of older North Leinster and a small part of Ulster, and Leinster, consisting of the remainder of the two ancient Lagenian fiths. This division subsists with little change down to the 11th century, and is described in detail in the "Book of Rights" (10th century). The grouping, however, is in some particulars theoretical rather than actual. Eastern Ulster is to be regarded as containing three kingdoms of equal status, Dalriada, of which the kings ruled also in Scotland; Ulaid, the successor of the ancient Uluti; and Dal Araidi, a kingdom of the Picts. Osraige ("Ossory"), nominally in Leinster, does not appear subject to the king of Leinster. In each major kingdom or group-kingdom, the component states or petty kingdoms are of two kinds, tributary and non-tributary. The non-tributary states are those whose kings are of the same sept as the superior king, though their pedigrees may have branched apart for centuries. In Munster, for example, about half the number of component states were ruled by kings of Eoganacht lineage, and these were not tributary to the king of Munster, who was also of that lineage. Distributed all over the country were remnants of ancient subjugated tribes, the *Aithech-thuatha*, made tributary and held in political subjection.

Oversea Raids and Migrations.—From about the middle of the 3rd century, Latin writings bear constant evidence of Irish raiding expeditions, and the older Latin name *Hiberni* or *Iverni* is almost wholly replaced by a new name, *Scotti*, which appears to be a Celtic word meaning "raiders." Linked with the *Scotti* are found the *Atecotti*, also a Celtic word meaning "the very ancient folk," and probably distinguishing the Irish of pre-Celtic origin from the dominant Celts. Towards the end of the 4th century, large bodies of *Atecotti* were enlisted in the Roman service under the emperor Honorius. Irish tradition fully reflects the evidence of Latin writers. As the Roman power weakened in Britain, Irish raids were followed by migratory settlements. There is abundant evidence of Irish settlers all along the western seaboard of Britain from Argyle to Devon. Irish dynasties sprang up in Wales and lasted there for centuries. In the 5th century, the kings of Dalriada, a small kingdom in the north-eastern angle of Ulster, extended their power over the Irish settlers in Argyle and the neighbouring islands, their descendants ultimately, in the 9th century, becoming kings of Scotland. Crimthann, king of Munster, is said to have held a fortress in Britain. Branches of his sept settled in Wales and Cornwall. Niall of the Nine Hostages is identified by Ridgeway with "the Scot" who, in Claudian's poem, "mobilized all Ireland" against Roman Britain. In this reign, St. Patrick was carried to Ireland a captive and with him in the same raid, as his confession says and his epistle repeats, "so many thousands of men." At the head of a later expedition, Niall was killed at sea by a Leinster prince. His successor, Nath-i, heading another raid, died on the Continent.

Introduction of Christianity.—There is evidence of Irish Christians, apart from the thousands of enslaved Christian captives, before the first Christian mission to Ireland. In 429, at the instance of Palladius, deacon of the Roman church, St. Germanus, bishop of Auxerre, was sent by the pope, St. Celestine, to combat the Pelagian heresy in Britain. It was doubtless in answer to an appeal made through Germanus that, in 431, "Palladius was sent, their first bishop, to the Scots believing in Christ." After a short stay in Ireland, Palladius passed over to northern Britain, where he died soon after his arrival. In 432, Patrick, a disciple of Germanus, was sent as bishop to Ireland. He was a Briton, son of a decurion under the Roman government, and probably a native of Gwent in Monmouthshire. He was carried off a captive in the reign of Niall and became a slave in north-eastern Ulster. After six years he escaped. His birth may be dated in 385, his capture in 401, his escape in 407. His mission in Ireland succeeded

rapidly. In 438 he was favourably received at the court of the high-king, Loeguire, son of Niall. In 439, doubtless in answer to a request sent to his patron Germanus, three bishops were sent to his assistance, Secundinus, Auxilius and Iserninus, the last also a disciple of Germanus. Patrick chose for his own see Armagh, beside the ancient Ulster capital. Secundinus had his church near Tara, the seat of the high-king; Auxilius, near Naas, also a royal seat in Leinster; Iserninus, driven out at first by Enda, king of Leinster, was restored later by Enda's son Crimthann, a Christian convert, and fixed his see at Aghade, near Rathvilly, where Crimthann lived. There is evidence that Patrick chose Baislex (*Basilica Sanctorum*), near Cruachain, the capital of the kings of Connacht, as the see of a bishop for that kingdom.

In the story of St. Patrick's reform of Irish law we may perhaps see an influence transformed by tradition into an event. A druid foretold to Loeguire: "He shall free slaves, he shall raise up men of lowly kin." In the written laws, two centuries later, a slave class no longer exists. St. Patrick's epistle condemns the enslavement of Christians. The earlier racial distinctions between conquerors and conquered, between Pict and Celt, survive only in antiquarian tradition, and all become known by the common name Goidil, "Gaels," or *Fir Erenn*, "Men of Ireland."

Political Events, A.D. 450-1000.—The descendants of Niall, *Ui Neill*, acquired territories in the regions annexed by conquest

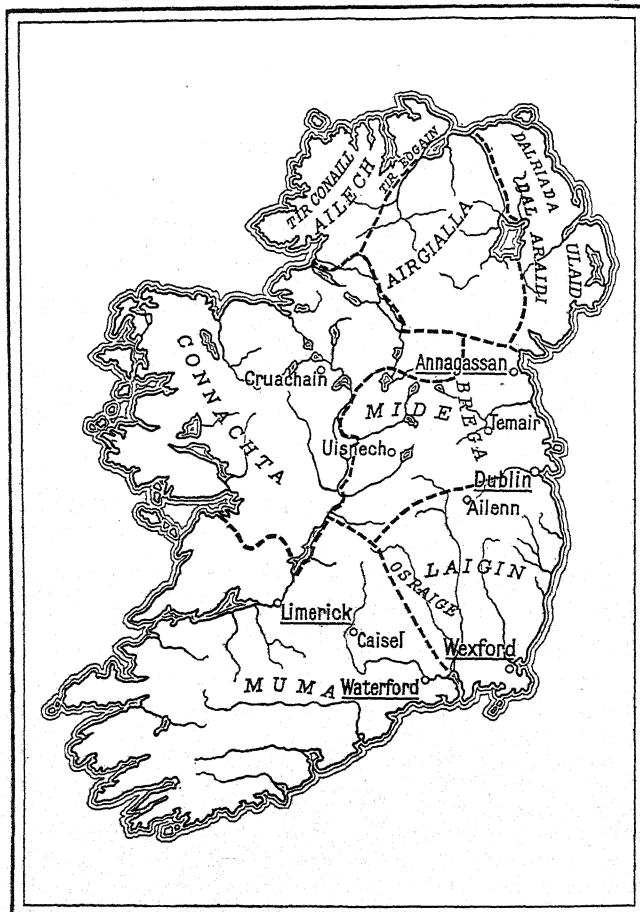

FIG. 2.—MAP OF THE SEVEN MAJOR KINGDOMS OF IRELAND, A.D. 500-900

These were Tir Conaill (Donegal); Airgialla (Londonderry, Armagh and Monaghan); Ulaid (Antrim and Down); Connachta (Connought); Muma (Munster); Mide and Brega (Meath); and Laigin (Leinster)

to their ancestral kingdom, Connacht. The other branches of their kin remained in Connacht. Loeguire was succeeded as high-king by Aillill Molt of a Connacht branch. Niall's descendants combined against Aillill, who was defeated and killed in the battle of Acha, A.D. 483. Thenceforward, until 1002, the high-kingship was held exclusively by the line of Niall. One group of his descendants, the "northern *Ui Neill*," held western Ulster. Another group, the "southern *Ui Neill*," dominated Mide, the main part of the old

north Leinster fifth. In 563, the Pictish territory west of the river Bann was annexed by the northern Ui Neill. In 575, the high-king, Aed, son of Ainmeri, held an assembly at Druim Ceta, on the border of that territory, and decisions were adopted limiting the privileges of the *filid* and regulating the relations of the kingdom of Dalriada in Ireland to the kings of Dalriada in Scotland and to the kings of Ireland. In 637, Domnall, king of Dalriada, invaded Ireland from Scotland. He was defeated in the battle of Mag Roth ("Moira") by Domnall, king of Ireland.

After the battle of Octa, the high-kingship passed without any regularity from one branch to another of the Ui Neill, being held by descendants of five of his sons. In 734, Flaithbertach, of the line of Conall, son of Niall, was deposed by Aed Allan, of the line of Eogan, son of Niall. Thenceforward the succession was confined to two branches, the kings of Ailech, descendants of Eogan, and the kings of Mide, descendants of Colman, these being respectively chief kings of the northern and southern Ui Neill, and the high-kingship was held by the kings of Ailech and Mide in a regular alternation, interrupted twice only, by the reigns of Congalach, king of Brega, 944-956, and of Brian Borama, 1002-14.

ECONOMIC AND CULTURAL DEVELOPMENT

Development of Monastic and National Culture.—The great development of Latin learning and of the monastic schools takes its origin from St. David's school of Menevia in Wales about A.D. 500. The kingdom of Dyfed ("Demetia"), in which this school was situate, had originated as an Irish colony, and remained in close intercourse with Ireland. St. David was of partly Irish ancestry and his school attracted many from Ireland. Among its earliest pupils was St. Finnian, who founded the monastery and school of Clonard, about 520. Clonard became the parent of other noted monasteries, notably Clonmacnois and Bangor, and, through its most famous pupil, St. Columban, of Derry, Durrow, Kells and other foundations in Ireland, as well as of Iona.

The language of these schools was Latin. The Latin classics were held in high esteem, and in some instances their survival is due to Irish zeal. When Theodore set up the teaching of Greek in Canterbury, he was beset by students from Ireland "like a wild boar surrounded by a troop of furious wolves." Scribes were continually at work providing copies of books. In the decoration of the more precious books, the art of illumination was highly developed. On the humanistic side, monastic learning was influenced by the traditions of Druidism. In the 7th century a fusion of the two cultures came about. In its early years a monastic chronicler introduced a framework of Irish history into his redaction of the Chronicle of Eusebius. A young noble, Cennfaelad, of the line of Niall, wounded in the battle of Moire (637), became a student in Tuaim Regon, where schools of the monks and the *filid* existed side by side. He broke away from the old druidical tradition by writing down the mnemonic formulae of Irish law. Cennfaelad, who died in 679, wrote also a number of poems on historical events and a short tract on the grammar of Irish. During the 7th century, an Irish written literature in prose and verse was extensive.

The Irish Missionaries.—In 563, Columban, then in his 43rd year, a descendant of Niall and a pupil of Clonard, having already founded the monastery of Derry on the site of the present city, led a colony of monks to the island of I ("Iona"), granted to him by the king of Dalriada. This was the beginning of the Irish missions overseas, the "surplus product" of the monastic schools. The work of Irish missionaries among the Picts, Angles and Saxons, belongs to the history of Britain. The continental missions began with Columban of the monastery of Bangor in Ulster, who, with a few companions, arrived in France about the year 574. Their range extended in time over a large part of France, the Netherlands, Germany, Austria, Switzerland and Italy.

The early missionary movement had its natural sequel in the sphere of learning. The part taken by Irishmen in the Carolingian revival of learning belongs to Irish history inasmuch as it exhibits the mental training given in Irish monastic schools and the scope and character of their studies. Clement the grammarian had a knowledge of Greek. Dichuill wrote a geography of the world in which he shows that his countrymen had travelled as far as Egypt

and had discovered Iceland. Dungal, theologian and grammarian, wrote for Charlemagne an explanation of the solar eclipse of 800. Virgilius taught the existence of the Antipodes. Eriugena, for his knowledge of Greek and the boldness of his philosophical speculation, is the most prominent intellectual figure of his time. At Glastonbury, under Irish masters, St. Dunstan studied arithmetic, geometry, astronomy and music. Irish monasteries, in Ireland and abroad, were prominent in the cultivation of music.

Rural Economic Development.—The Irish laws point to a large development of rural industry in the period in which they were first written, preceding the Norse incursions. They deal minutely with the enclosure, subdivision and fencing of lands for tillage, the measurement and valuation of land, the management of crops and domestic animals, and innumerable details of husbandry, including milling, dyeing, spinning and weaving, dairying, malting, meat-curing, etc. The principal crops were wheat, barley, oats, flax and hay. Dye-stuffs were grown. Irish hounds were in high repute. St. Patrick, in his escape from captivity, joined a company of Irish traders whose chief merchandise was hounds. Watermills were owned and worked jointly by landholders.

The Paschal Controversy.—The Irish Church, in the dating of the Easter festival, followed a method introduced by its founders. Irish missionaries abroad found a different method under papal authority. About 631, the Roman computation was introduced in the southern parts, in northern Ireland somewhat later. Iona held out longest for the Irish tradition, even in opposition to its abbot, the celebrated Adamnan, and did not adopt the Roman Easter until 716, 12 years after his death.

Norse Invasions and Settlements.—The first appearance of the Norsemen on the Irish coast is recorded in 795, their first inroad in 807. Thenceforward there are frequent plundering raids, sometimes far inland. By degrees the Norsemen took possession of all the islands of Scotland, of Caithness, Argyll, Galloway, and the Isle of Man. In 841 they seized and fortified two ports, at Annagassan, between Dundalk and Drogheda, and Dublin. About the same time a fleet under Thorstein passed up the Bann to Lough Neagh. He afterwards sailed round to the Shannon and took possession of Lough Ree in like manner. Thorstein was captured in 845 and put to death by Mael-Sechnaill, king of Mide, who in 846 became king of Ireland. Large invading forces were defeated in 847. The turning point of these invasions was reached in the reign of Aed Findliath, high-king from 862 to 879, who forced the Norsemen to abandon all their stations in the northern parts of Ireland. At the same time the Norse kings of Dublin reached the height of their power, waging war in England and Scotland, and so nearly dominating Ireland that in the years 873, 876 and 878 the high-king was unable to hold the assembly of Tailtiu. Waterford in 914 and Limerick in 920 were occupied by the Norsemen without opposition. In 917, Niall Glundub, high-king, endeavoured to dislodge them from Waterford but they defeated a Leinster army coming to his assistance and forced him to withdraw. In 919, Niall led an army against Dublin, and in a battle where the Phoenix park is now he was defeated and killed. The permanence of the Norse settlements in Dublin, Waterford and Limerick became assured. Landed colonies spread out from Dublin and Waterford. Without quite abandoning piracy, the Vikings became traders in close intercourse with the Irish, and their commercial towns form a new element in the life of the country, typified in Wexford, which does not appear in warfare until the siege of 1169. The combination of war and commerce led to a recrudescence of slavery, and imported slaves are mentioned in the "Book of Rights" (about A.D. 900).

About 964, Mathgamain, king of Dal Cais, one of the petty kingdoms of Munster, became king of Munster, displacing the ancient Eoghanacht line. In 968 he defeated the Norse of Limerick and captured their city. In 976, he was captured and put to death by two Eoghanacht princes, one of whom, Mael Muaid, became then king of Munster. In 978, Mael Muaid was defeated and put to death by Brian, brother of Mathgamain. Brian, having gained the kingdom of Munster, kept steadily increasing his power. His claim to suzerainty over Leinster forced the Leinster king into close alliance with the Norse of Dublin. In 999 their

united forces were defeated by Brian at Glen Mama, near Dublin, and they agreed to become his allies and supporters. In 1002, Brian became king of Ireland by the submission of the high-king Mael Sechnaill II. The Irish and Norse accounts agree in bearing witness to the high character and good government of Brian. The kings of Dublin and Leinster, however, chafed under his suzerainty. In 1013, Sigurd, earl of the Orkneys, had for a Christmas guest the Norse king of Dublin, Sigtrygg, and a compact was made between them. Sigurd was to gather from all parts the greatest possible host of Norsemen and to bring them before Easter to Dublin, where they were to be joined by the forces of Dublin and Leinster to give battle to Brian and, if they were victorious, Sigurd was to have the kingdom of Ireland. Brian learned of these preparations, met the Norse army at Clontarf, near Dublin, on Good Friday, 1014. He was joined by the deposed high-king, Mael Sechnaill. The Norsemen and their Leinster allies were defeated and Earl Sigurd was slain, but a Viking chief, who had taken refuge in a wood, sallied out in the rear of the Irish army and killed Brian in his tent.

Though the battle of Clontarf removed the prospect of a Norse conquest it brought a period of unsettlement. All the chief dynasties had lost their prestige, and, except in Connacht, new rivalries and fresh pretensions to power, based on force and careless of tradition, arose everywhere. Brian's son, Murchad, who had already gained a reputation hardly less than his father's, had fallen in the battle. Of the sons who survived, none was able to sustain Brian's power. Mael Sechnaill was restored to the high-kingship and held it until his death in 1022. After him, for half a century there was no acknowledged king of Ireland.

Then followed the period of the high-kings "with opposition," i.e., not acknowledged by a minority of the provincial kings: Toirdelbach, grandson of Brian, 1073-86; his son Muirchertach, 1086-1114; these were kings of Munster; in opposition to Muirchertach, Domnall Ua Lochlainn, king of Ailech, who died in 1121; Toirdelbach Ua Conchubair, 1118-56, king of Connacht; Muirchertach Ua Lochlainn, 1156-60, king of Ailech; Ruaidri Ua Conchubair, 1166-74, king of Connacht. The centralized feudalism established in England by William the Conqueror had an apparent influence on the policy of these kings. One after another they sought, for the most part without success, to set aside the ancient tradition of local autonomy and to exercise direct authority outside of their hereditary jurisdictions. Thus Toirdelbach Ua Briain about 1075, appointed a kinsman of his own to be king of Tulach-Og in Ulster. Toirdelbach Ua Conchubair, in 1118, divided Munster into two coequal kingdoms; in 1125, deposed the king of Mide and appointed three kings in his stead; in 1126, made one of his sons king of Dublin and Leinster; in 1129, built the first castle in Ireland, commanding the passage of the Shannon at Athlone.

The last effort to establish Norse domination was made by Magnus, king of Norway, who in 1098 came with a strong fleet and restored the Norwegian sovereignty over the Scottish islands, Cantire, and the Isle of Man. In 1102, Magnus, then in Man, threatened an invasion of Ireland but agreed to a year's truce. In 1103 he landed on the Ulster coast where he was killed.

The period of political ferment which followed the success of Brian over the ancient chief dynasties was also a period of new growth in religion, literature and the arts. The movement for religious reform, mainly in the direction of a Catholic uniformity and the removal of abuses in matters of ecclesiastical discipline and observance, was led by Gillebert, bishop of Limerick, and Cellach (Celsus), bishop of Armagh and primate, in the beginning of the 12th century, and by the successor of Cellach, Maelmaedoc Ua Morgair, better known as St. Malachy. The outstanding feature of the abundant literary output of this time is enthusiasm for ancient national tradition. It became customary to compile tomes, each forming a kind of library of traditional lore, comprising sagas, poems, genealogies, etc. A number are still extant.

BIBLIOGRAPHY.—Macalister's *The Archaeology of Ireland* (1928) summarizes and explains the archaeological data. The data from Greek and Latin writers are given under appropriate headings in Holder's *Altceltische Sprachschatz*. For ancient Irish traditions bearing

on the predocumentary period, the chief book of reference is Best's *Bibliography of Irish Philology and of Printed Irish Literature* (1913), which also gives particulars of the published chronicles. Irish contemporary chronicling begins towards the end of the 6th century and continues thenceforward until modern times. (E. MacN.)

HISTORY FROM 1166 TO 1485

The Anglo-Norman Invasion, 1166-1175.—Early in his reign, 1155, Henry II. of England had, through his envoy, John of Salisbury, received from Adrian IV. the grant of Ireland "as an inheritance," on condition that he should reduce to order the Irish Church and State. The so-called "Bull," *Laudabiliter*, which defines this grant, rests on the sole authority of Giraldus Cambrensis; how far it is genuine is one of the puzzles of history, but the general submission of the Irish to Henry later would imply that some such papal privilege was in the air.

Henry had to put his project aside for the time, and when the invasion came, it was a feudal one and directed from south Wales which was full of Norman adventurers. The first invaders, Maurice Fitzgerald, Robert FitzStephen, Raymond "le Gros" de Carew and others were sons or grandsons of the famous Welsh princess Nesta, and vassals of Richard FitzGilbert de Clare, called "Strongbow" in Irish tradition, earl of Pembroke.

Their opportunity came when Dermot MacMurrough, king of Leinster, expelled by his enemies, decided to seek aid in England and arrived in Bristol with his beautiful daughter Eva (Aoife) in Aug. 1166. He was there referred to Henry, found the king in France, was graciously received and given permission to raise forces in Britain. Returning to Wales, he won FitzGilbert over by the offer of his daughter's hand with apparently the succession to Leinster. He also enlisted "the sons of Nesta" in his cause and they found volunteers among the Welsh and Flemings of South Wales and Pembroke. Returning to Leinster, where his son Donal Kavanagh, whom Giraldus calls illegitimate, was holding out for him, he held his ground until successively Fitzgerald, FitzStephen, Raymond and finally Earl Richard himself arrived, the latter landing at Waterford in Aug. 1170 with 200 knights and 1,000 men-at-arms.

The successes of Dermot, backed by these professional fighters, were rapid; Danish Waterford was taken; the marriage of Eva and the earl celebrated; and by a rapid march Dublin also was captured and a relieving force under the high-king scattered, late in 1170. Leinster and Ossory were reduced, but the death of Dermot the following May made the situation difficult. The Irish regarded his son Donal as the true heir, but FitzGilbert considered himself king of Leinster, and anyway in feudal theory was, in virtue of his wife, lord of the province. But he was hemmed up in Dublin in mid-summer by a national levy raised by Rory O'Connor, king of Connacht, and though this attack was repelled, it was uncertain whether he could hold his own. Therefore when Henry, fearful lest a new Norman State should arise across the Irish channel, resolved to come to Ireland, Strongbow placed his conquests at his suzerain's feet.

Henry landed near Waterford on Oct. 17, 1171, with an imposing army, but a conquest in arms was not necessary, and in fact the peaceful submission of the Irish leaders was prompt and widespread. The king marched to Lismore and Cashel and finally to Dublin, where he spent the winter, leaving Ireland on April 27, 1172. Into this short period he packed the rough essentials of a government. At Dublin and elsewhere he received the homage of all the kings of Ireland except those of Connacht and Ulster. To Strongbow he granted the "Land of Leinster," confirmed the Geraldines and others in their fiefs, and annexed to the Crown the Danish kingdom of Dublin. He gave the capital to "the men of Bristol," took the Ostmen under his protection, and appointed Hugh de Lacy governor of the colony. He did not scruple to confer on De Lacy the whole of Meath, though its native king, O'Melaghlin, had recently submitted, and the grant illustrates the inevitable clash of feudal and Irish law. Meanwhile during the winter the Irish bishops met at the Council of Cashel and, after enacting various reforms, declared (according to Giraldus): "Divine offices shall be celebrated according to the forms of the Church of England, for it is just and right that as Ire-

land has received her lord and king from England, she should accept reformation from the same source." This of course was an inspired assurance of the task with which the papacy had commissioned Henry. The submission of the Church was complete, nor was it a packed assembly, for though Christian, bishop of Lismore and papal legate, seems to have been on Henry's side, Laurence, archbishop of Dublin, and the native prelates of Cashel and Tuam were present. Thus was Ireland presented to the English Crown as a papal fief; such was the basis of its authority till 1541, and the Irish themselves accepted the fact.

Meanwhile the adventurers were attacking Desmond, though its king had submitted to Henry; De Lacy was organizing Meath; and John de Courcy conquered in Antrim and Down a principality for which he could show no royal patent. Strongbow enfeoffed Leinster deeply with Normans, giving for instance the barony of Naas to Maurice Fitzgerald. Strongbow died in 1176, leaving only a daughter, who later married William the Earl Marshal and brought to him "the land of Leinster." Ulster and Connacht were still unconquered, and in 1175 by the Treaty of Windsor, Henry acknowledged Rory O'Connor as king of Connacht under him.

John as Lord of Ireland, 1175-1216.—At the Council of Oxford in 1177 Henry created his son John *Dominus Hibernie* and granted Desmond to FitzStephen and Milo de Cogan. Eight years later (1185) John himself visited Ireland. A fresh series of grants were made, and William de Burgh and Theobald Walter "le Botiller" got wide lands in north Munster, and Theobald de Verdun about Dundalk. The resentment of the Irish was shown in the assassination of Hugh de Lacy, and the lesson was taken to heart later in John's reign when Cathal Croiderg O'Connor, brother of Rory, was confirmed in the kingdom of Connacht and Donnchad O'Brien in that of Thomond west of the Shannon.

With John the lordship of Ireland was united with the English Crown, and to this king belongs the credit of first establishing a civil government at the expense of the conquistadors. He dispossessed De Courcy, and gave the earldom of Ulster to Hugh, brother of Walter de Lacy, earl of Meath, but soon repented of making this family too great, and in a personal campaign in Ireland in 1210 expelled them both. During his short stay in Dublin he organized a permanent government under a justiciar, and "with the common consent of all men of Ireland ordained that the laws and customs of the realm of England should be kept therein."

After his defeat over Magna Carta, John had to restore the Lacys, and the feudal caste under Henry III. bent its energies upon the subjection of Ireland. When Richard de Burgh got a grant of all Connacht in despite of the claims of Felim O'Connor, conquered it and divided it among his followers (1235), and Maurice Fitzgerald acquired a claim to Tyrconnell, a complete conquest seemed probable. But during this period two great native dynasties arose in Ulster, the O'Neills and O'Donnells, and they repelled the Norman attacks, finding a new and potent weapon in those professional fighters, the "Galloglagh" or "galloglass" (a word meaning "foreign soldiers"), Hebrideans of mixed Gaelic-Norse blood who now began to flock into the north. On Connacht, however, the De Burghs kept firm hold, leaving to the O'Connors only a few cantreds of Roscommon. The power of this family was increased when in 1264, after the extinction of the Lacys, Walter de Burgh was created earl of Ulster. The native race, though only partly successful, now broke the spell of Norman victory. Brian O'Neill was elected high-king and raised a Gaelic confederacy, but was defeated and slain at Downpatrick in 1260. But the next year the MacCarthys overthrew a colonial army at Callann, and henceforth ruled undisturbed over south-west Munster, their chief taking the name MacCarthy More. So when Edward I., in 1276, granted to Thomas de Clare the "Land of Thomond," Turloch O'Brien took up arms, and the De Clares were finally expelled in the war which ended in 1318.

In the early years of Henry III. the central Government was steadily built up. Magna Carta was sent over, the whole framework of English law was introduced, and Ireland had an administration under the justiciar and a parliament of peers and prelates, while the county organization was extended over the planted

areas.

Great numbers of the Gaels had fallen under Norman lords, and while some were already villeins ("betaghs") under the old system, and remained so on the new manors, many of the colonists tried to reduce all Irishmen to the same level. Those living among the English and suffering from a denial of English law strove to procure it, but though the Government was not unwilling, the colonists opposed emancipation. The Irish who lived under Brehon law had less desire to exchange it for English law, but under the pressure of the new domination they naturally aspired to have its legal advantages. The chiefs especially sought to have their tenures legally established under the Crown, a benefit which, except in a few minor cases, had been denied them. The royal Government was to blame for not embracing the Irish within the law by edicts rigidly enforced, but, indeed, to reconcile and blend two races so far apart in language and tradition was a huge task which only a resident monarchy could have achieved.

English Lordship at its Height, 1272-1307.—Under Edward I. a second attempt was made to create a real central authority, and a series of justiciars, of whom John Wogan, viceroy from 1295 to 1307, was the ablest, extended the area of common law and did something to reduce the feudal liberties. The baronial interest, however, was too strongly entrenched, and Edward had to placate it, so he added to the ranks of the magnates by giving "the land of Decies and Desmond" to Thomas, head of the Munster Fitzgeralds. Wogan's greatest achievement was to summon a parliament in 1297 in which knights and the common clergy were included, and nine shires and five liberties sent representatives. In 1310 the towns also sent deputies, and thus Ireland received a legislative body which lasted till 1800. It was an Anglo-Irish assembly in which the native race had no spokesmen.

A series of disasters now shook the ill-founded State to its very base. Fresh from his victory at Bannockburn, Robert Bruce despatched his brother Edward to win the Crown of Ireland, which a league of Irish chiefs under Donal O'Neill, *Rex Ultonie*, offered to him. When Edward Bruce landed with an army of veterans near Larne in May 1315, almost all the native race rose in arms, and not a few of the older stock of the Englishry joined Bruce. He defeated Richard the "Red Earl" of Ulster at Connor. On May day, 1316, he was crowned king of Ireland on a hill near Dundalk, "the Gaels of Erin proclaiming him king of Ireland," says the annals of Loch Cé.

The English cause was at last saved: Bruce failed to take Dublin, Felim O'Connor, at the head of a great Irish confederacy, was defeated and slain by a colonial levy at Athenry in Aug. 1316, and a new viceroy, Roger Mortimer, put spirit and energy into the Government. Bruce himself was overwhelmed at Faughart, near Dundalk, by an army under John de Bermingham and fell in the battle (Oct. 1318). The Scottish fire was thus quenched and Edward II. recovered a kingdom he deserved on every count to lose. Little or no vengeance was taken, and Mortimer was instructed to admit the aggrieved Irish to English law and liberty, an edict again without much effect.

The Irish Revival.—For a time all seemed fair and the peerage between 1316 and 1329 was strengthened by the creation of new earldoms, that of Kildare, given to John, head of the Leinster Geraldines, that of Desmond, given to Maurice, head of the Munster Geraldines, and that of Ormond, given to James Butler. In Ulster, the true key of the colony, the power of the earls now covered the whole coast from Carlingford to Derry. But an element of discord was found in the older colonists who resented the dominance of the great lords, claimed that succession should go to heirs male instead of heiresses who conveyed lands to English absentees, and began to form clans of their own (*naciones et cognomina*). In 1333 the young earl of Ulster, William, was murdered by his own tenants, the Mandevilles, near Belfast, leaving only a daughter who later was married to Lionel, duke of Clarence. The O'Neills became supreme in mid-Ulster and the greater part of Antrim and Down, where they founded a new State, Clondeboy.

Connacht was at the same time lost to the English interest. Two cousins of the murdered earl, Ulick and Edmund de Burgh,

seized on the family lands and founded respectively the Burkes of Clanrickard and Mayo, known to the Irish as MacWilliam Uachtair, "the upper MacWilliam," and MacWilliam lochtair, "the lower MacWilliam." Though they maintained a certain English tradition of law and land-tenure, spoke French, and boasted their Continental descent, they were obliged amid so Irish a population to speak Gaelic and marry Irish wives.

As a result of such events an Irish revival alike in arms, language, law and civilization, displayed itself in every part of the island, and the Gaelic race recovered large parts of Ulster, the midlands, Connacht and Leinster. Even in the latter province the MacMurroughs became the terror of the lowland English and the descendants of Donal Kavanagh resumed the title "king of Leinster." Absenteeism here had left the lordships of Carlow and Wexford open to Irish attack.

Efforts to Restore English Lordship, 1333-1399.—Only a great army led by the king in person could have reconquered Ireland, and the young Edward III. had thoughts of coming over, but soon abandoned it for Scotland and France. The colony dwindled, and an Anglo-Irish parliament at Kilkenny in 1341, summoned without leave by the earl of Desmond, expressed its resentment against "the English by birth" who misgoverned Ireland, and complained of the decay of the revenue and the loss of

Kilkenny, Wexford, Waterford and Tipperary. The decay of the colony was attributed to a general lapse into Irish language, law and habit, intermarriage and fostering, and the maintenance of Irish bards. Therefore the English were forbidden to make such alliances with the Irish or to use Brehon or "March" law, and along with the Irish who dwelt peaceably among them, were ordered to take English surnames, speak English, and follow English law and custom.

The purpose of these statutes was to preserve as large an area as possible for England at the cost of abandoning the rest. The king's sovereignty over the whole island was not renounced, but the independent Irish were henceforth treated as "Irish enemies," outside the pale of English law and loyalty, and unable to plead in or profit by the civil courts, to marry, purchase, possess or inherit land among the English. Up to the end of the 16th century the chiefs were held to have no right to their lands except by prescription and usurpation.

But nothing could recall the "degenerate English" from friendly intercourse with the *meri Hibernici*. The old Gaelic civilization, badly shattered in the 13th, recovered much of its strength in the 14th century, and with its music and poetry, the charm of its language and its women, and the aptness of its law, laid an irresistible spell on the older Englishry.

Lionel's only daughter marrying Edmund Mortimer, earl of March and lord of Trim, carried to him the earldom of Ulster, and this great lord came over as viceroy in 1380, but died prematurely. To buy off the Irish chiefs with Black-rents was now the poor device of the colonists, whose most dreaded foe was Art MacMurrough, king of Leinster. More than anything else, this chief's activities brought about the first royal visit since 1210. Richard II. arrived at Waterford in Oct. 1394 with a large army, attended by Roger Mortimer and other peers, and stayed in Ireland till May 15, 1395. His general policy for the "Irish enemies" was to secure their homage and confirm them in such lands as they had not "usurped," but with one exception; Art and his Leinster "urraghts" or vassals were to be induced to evacuate Leinster for other parts of Ireland and leave the province open to a new English plantation. This was achieved in both cases as far as paper went; almost all the ruling chiefs, headed by Niall O'Neill, *Princeps Hibernicorum Ultonie*, came in and did liege homage and entered into indentures with the king.

But on Richard's departure MacMurrough refused to fulfil his extraordinary bargain. Roger Mortimer, left behind as viceroy, was slain by the Wicklow Irish in 1398, and Richard in fury hurried over to Ireland again in 1399. His armies could do nothing against the light-armed Irish in their forests, and the unfortunate king returned to England only to meet his own doom.

The Great Earls, 1399-1452.—There is little of importance to record of the dwindling "English land" during the Lancastrian age. An occasional strong viceroy, such as John Talbot, afterwards the famous earl of Shrewsbury, could do little against the "Irish enemy," the "degenerate English," and the "English by blood," who resented government from Westminster. A hope of uniting the Celts and Englishry was found in Edmund Mortimer, now earl of Ulster, who came over as viceroy and received the homage of O'Neill and other chiefs, but died of the plague in 1425. The old English and the Gaels transferred their affections to his nephew, Richard, duke of York, and in the wars of succession in England were almost to a man for the White Rose.

In reality three great earls now ruled Ireland. James of Desmond brought the greater part of counties Limerick, Cork, Kerry and Waterford with their towns under his absolute rule, James "the White," earl of Ormond, was equally dominant in Tipperary and Kilkenny, and Kildare in Leinster. The three worked together, dominated the Dublin Government in spite of an "English interest" headed by Talbot, took the lead of an Anglo-Irish "Home Rule" party and built up a rampart of feudal independence which it took the Tudors later almost a century to break down.

Ireland and the Wars of the Roses.—"Aristocratic Home Rule" may till 1495, and indeed till 1532, be written over Anglo-Irish history. The Wars of the Roses were to the Old English an occasion to secure colonial independence. Richard, duke of York,

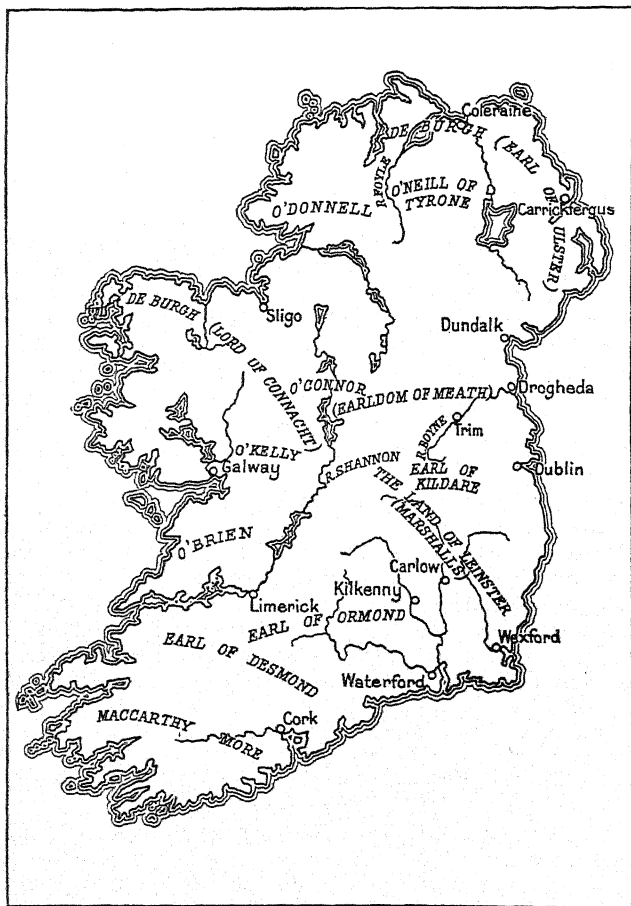

FIG. 3.—MAP OF MEDIAEVAL IRELAND, SHOWING THE LANDS OF THE RULING FAMILIES WHEN THE ENGLISH POWER WAS AT ITS HEIGHT, c. 1330. In addition to the counties governed directly from Dublin, several great earldoms had been created at this date; but that of Meath, belonging to the Laocys, had, owing to the extinction of this family, fallen into two portions, that of W. Meath (De Verdun) and that of Trim (Mortimer).

a third of the land to the Irish. The capacity of this "middle nation," "Irish to the English and English to the Irish," to turn into temporary rebels was often to puzzle England.

Finally at last a royal prince was sent, and Lionel, duke of Clarence, ruled as viceroy for six years (1361-67). The Statutes of Kilkenny are the one memorial of his rule. These enactments defined the "English" or "obedient" land as the counties and liberties of Louth, Meath, Trim, Dublin, Carlow, Kildare,

"This people of Ireland," said a later observer, "did ever, both English and Irish, love to be ruled by great persons." Garret More, who ruled Ireland till his death, in 1513, was such a personage. As deputy he controlled Dublin and the Pale, his earldom made him supreme in Leinster, and by vassalage, fee or marriage, he attached numbers of Irish chiefs to him, of whom the greatest were Conn O'Neill and Hugh O'Donnell. But his loyalty was dubious, and in his later years he was intriguing with Scotland against the young Henry VIII. His son Gerald, called "Garret Oge" ("the younger"), succeeded to this hereditary power, but to maintain it became an ever harder task. To the hostility of the Butlers was added that of Wolsey, who urged Henry against so overgrown a subject as "the king of Kildare." Gerald was again set aside, and the earl of Surrey came over as lord-lieutenant, for two years, in 1520-22. His reports, backed by such tracts as D'Arcy's *Decay of Ireland*, told the same tale; Kildare, "using the sword the king had committed to him to extinguish the fame and honour of any other nobleman within the land"; the Irish speech and habit universal, even in the Pale; the "March English" everywhere imposing on their tenants coyness and livery, quarterings of kern and galloglass and other such "Irish exactions"; the Irish, independent under their chiefs. Though Gerald was restored once again, the Butler-Wolsey alliance grew more dangerous, and when the divorce question began and Henry conferred the vacant earldom of Ormond on Sir Thomas Boleyn, grandson of the last earl, and made Sir Piers Butler earl of Ossory, it seemed impossible for him to escape. Yet so astute a man might have weathered through even yet but for a young and foolish son. Recalled to London in 1534, Gerald instructed his heir, Thomas, Lord Offaly (called "Silken Thomas"), to be ruled by the wise heads of the council. The Butler faction spread the rumour that Kildare had been done to death, and Offaly at once flew to arms. His father did, indeed, die in the Tower, but with mortification and dismay; a new deputy, Skeffington, arrived, and Thomas, while barring himself from pardon by offering Ireland to the emperor and declaring himself of the pope's sect against the heretic Henry, had finally to surrender at discretion, and in 1535 was executed at Tyburn with five uncles.

The Reformation of the Irish Church.—The new policy in Church and State could now be carried through, and henceforth English viceroys and obsequious Anglo-Irish officials directed the Government. Grey summoned a parliament in 1536-37, which declared Henry supreme head of the Church and voted the dissolution of the abbeys. It is certain that almost no desire for such "reformation" existed in Ireland; lords and chiefs might accept bribes of monastic lands, but even at the end of the reign scarcely any abbeys had been dissolved outside Leinster, and not till 1607 could those of Ulster be confiscated. Within the region of the Pale the abbeys were centres of English education, speech and civility; outside, they were the home of Gaelic culture, and civilization in general suffered by their extinction. George Browne, an Englishman, was sent over as archbishop of Dublin, to preach the royal supremacy and, before the end of the reign, some 14 or 15 of the older bishops temporized and accepted it, in the belief that the Church was still Catholic.

On its civil side the new policy had much support, not only in Piers Rua, who was at last created earl of Ormond, but in great numbers of the rural tenantry, desirous of being released from the exactions of the great lords. To recall the Old English to their natural allegiance was no insuperable task, and had the Tudors never abandoned the old faith it is probable that they would have commanded the entire loyalty of the "first conquerors." When, however, the Reformation began in earnest the Old English grew steadily alienated, and the introduction of new colonies became the royal policy.

Towards the Gaelic chiefs Henry adopted the plan of surrender and re-grant, by which they could surrender the lands they held and receive them back on tenure of knight-service to the Crown. To the great ones he offered to grant titles, but in return they must accept him as supreme in Church and State. St. Leger, who came as deputy in 1540, pointed out that a new title must be found for the Crown in Ireland, "for of long continuance Irish-

men have supposed the regal estate of this land to consist in the bishop of Rome and the lordship of the kings of England here to be but a governance under the obedience of the same." Accordingly a parliament was summoned in June 1541, and six Gaelic chiefs approved the act that made Henry king of Ireland.

By the skilful handling of St. Leger, Manus O'Donnell accepted Henry as his lord and king, renounced the pope's authority, consented to serve the deputy with an agreed number of horse and foot, and to accept whatever title the king should give him. Conn O'Neill surrendered his ancestral claims, accepted Henry as king, and in 1542 was made earl of Tyrone; Murrough O'Brien became earl of Thomond, and Ulick Burke, earl of Clanrickard.

Ireland Under Edward VI. and Mary.—Under the two Protectors the Reformation was pushed on apace, and the anger of the common people at the destruction of monasteries and the plunder of the Church was now shared by the great. Dowdall of Armagh, though one of Henry's bishops, defended the mass, and only five Protestant bishops held their ground, of whom most active was the Englishman, John Bale of Ossory, a Genevan reformer.

On her accession, the Catholic Mary retained the title of queen of Ireland, but had to leave the abbey lands to the grantees. St. Leger became deputy again, Dowdall returned, and, as a part of the general reconciliation, the exiled Gerald was restored to the earldom of Kildare. But in spite of religious unity, there was little peace. Henry had begun the policy of trying to rule the further provinces through the new earls, but these were opposed by the vested interests of those who preferred the old order, in which the O'Brien or MacWilliam was but an elected captain of his "nation," holding for life, not an hereditary official landlord. This was especially seen in the North, where Shane O'Neill, claiming to be Conn's eldest legitimate son, came out as champion of the old Gaelic order, preferred being "the O'Neill" to any English title, and opposed his brother Matthew, baron of Dungannon, whom he declared to be a bastard. The conflict of State feudalism and Gaelicism became general. In Leix and Offaly, where O'More and O'Connor Faly were sovereign, a determined stand was made against the extension of English law, and after a long border war the Government decided to annex and partly plant these areas. Lord FitzWalter, afterwards earl of Sussex, replaced St. Leger in 1556, and with him a policy of confiscation and plantation was adopted. The two lands were shired as King's and Queen's counties and divided into an eastern more fertile area, in which Englishmen were to be planted, and a western area, which was to be left to the natives holding by common law tenure.

The Elizabethan Reformation.—Elizabeth succeeded to the throne in Nov. 1558, and under the earl of Sussex the State religion was finally established. In a parliament of 1560, which represented ten counties and 28 towns, the Acts of Supremacy and Uniformity were passed and recusancy fines were imposed. Outside Dublin the supporters of the Established Church were a handful, and it soon became clear that the Old English were even more determinedly Catholic than the Irish. As loyal subjects their position was strong, and a constitutional resistance was successfully waged by the lawyer class, who were strong in the Commons, the town corporations and even the Government.

Ireland, with its feudal and Gaelic lordships, was a standing offence to a centralizing monarchy, and to extend the shireland and introduce sheriffs, garrisons and English law became the avowed object of the Tudor Government. But every such extension, which had to proceed piecemeal, met the opposition, alike of the chiefs and the Old English lords; and the resistance of the Gaelic population was the more deadly of the two, for their military resources were greater, their native civilization was dearly cherished, and their hatred of the Saxon was deeply rooted. The greatest of these captains, Shane O'Neill, was, in native eyes and, almost, in fact, king of Ulster. From the four counties, Tyrone, Derry, Armagh and Antrim, where he was overlord, his ambition was to rule the whole province, and after Matthew, baron of Dungannon, had fallen in an affray, and his son Hugh was taken to be educated with the earl of Leicester

RURAL AND URBAN SCENES IN IRELAND

1. View of Glendalough, "The Glen of Two Lakes," Co. Wicklow, Ireland. Known as the "Town with the seven churches," because of the group of early Celtic churches established here by St. Kevin
2. The Giant's Causeway, about three miles from Dunluce, Ireland. Cliffs of basalt make a bay from the centre of which shoots out this natural mole, compacted of huge basalt crystals
3. O'Connell street, Dublin. Formerly the thoroughfare was known as Sackville street but when the O'Connell monument was erected in 1880 the name was changed
4. Working in the peat bogs of central Ireland
5. Kilmessan Village, near the hill of Tara, County Meath, in the province of Leinster
6. Air view of Belfast, the metropolis of Northern Ireland, showing the City Hall

and in Elizabeth's court, Shane had the field to himself. He proceeded to subject O'Donnell on one hand and the Scots of Antrim on the other, and having been invited over to court in 1562, he so flattered the queen with his Irish tongue that he returned in triumph as "The Lord O'Neill." When Sir Henry Sidney arrived as deputy in 1565 the power and influence of Shane overshadowed all Ireland, but in a rash attack on Hugh Duv ("the Black"), chief of Tyrconnell, he was routed at Farsetmore, and, flying to his enemies, the MacDonnells, was by them murdered in 1567.

The Desmond Wars.—Desmond was an "Old English" regality as Tyrone was a Gaelic State. The new earl, Gerald, was deeply suspicious of the "forward policy" which menaced his palatine authority. He and Thomas, earl of Ormond, were hereditary enemies, and after a pitched battle at Aifane, in 1564, they were summoned to London, where Desmond spent many years of semi-captivity till 1573. The Geraldines, therefore, took as captain the earl's cousin, James "FitzMaurice" FitzGerald, who planned a league which should defend at once the earl's "liberties" and the Catholic faith. Exclusion from office under the Oath of Supremacy was now alienating the "English of the Pale," and religious discontent was fanned by the Jesuit missions, which, from 1561, were many and determined. Catholic Ireland had its colleges at Douai, Salamanca and Louvain, and if rebellion needed the highest sanction it was found in the papal bull of 1569, which excommunicated Elizabeth and released her subjects from obedience. It was unfortunate that at such a time the Government allowed Sir Peter Carew, a Devon gentleman, to get legal possession of wide lands in Carlow and Cork in virtue of very musty pedigrees. With him began the age of the adventurers and land-speculators, the Raleighs and the rest, and Old English and Irish now felt that even their property was insecure. FitzMaurice was accordingly able, in 1569, to kindle a widespread revolt in Munster and Leinster, which Sidney, Carew and Gilbert stamped out with a severity that set the note for future "pacifications," and FitzMaurice submitted in 1573.

Six years later he was the leader of a new war in Munster. The Continental side of it was organized by the Spaniard, Oviedo, later "titular" archbishop of Dublin, but though the pope offered spiritual assistance, Philip gave little or no material aid, and FitzMaurice had but a small band with him when he landed in Kerry in 1579. With him was the English Jesuit, Sanders, who proclaimed a plenary indulgence for all who would fight against "Elizabeth, pretended queen of England." There was a widespread rising, but the only man who could have made it formidable disappeared when FitzMaurice fell in a petty affair at Castleconnell. The earl himself was driven into rebellion, and 800 Italians, sent by the pope, were besieged at Smerwick by the deputy and, after surrender, pitilessly massacred. Desmond was hunted down and killed and the South was pacified by the usual methods. Confiscation was henceforth to follow the horrors of war, and while the earl and his chief followers were attainted, some 600,000 acres were declared forfeit. In the end only some 200,000 were granted to newcomers like Raleigh.

Ireland was now so "pacified" that even in the year of the Armada she scarcely moved. Sir John Perrot, deputy from 1584 to 1588, encountered in the parliament of 1585 a strong and well-led "Recusant" party, but though Archbishop Loftus urged enforcement of the penal laws, the gallant and tolerant viceroy refused to force men's consciences. He was empowered by this parliament to make, with the chiefs and gentry of the West, "the composition of Connacht," by which they were confirmed in their immediate demesnes with rents from the rest of their "countries" in lieu of feudal and Irish regalities, and to serve the deputy in arms, pay rent to the Crown and hold by English tenure. The result was that Connacht, under its Gaelic and Norman proprietors, remained, on the whole, loyal up to 1640.

The Tyrone War, 1594-1603.—One of the last acts of Perrot was to have the young Red Hugh (Aodh Ruadh) O'Donnell kidnapped and sent to Dublin Castle as a hostage for the loyalty of his father, Hugh "Duv." The results were disastrous, for, up to now, the O'Donnells had been allies of the State, but the

alliance was now shattered. After five years Red Hugh escaped to become "the O'Donnell" and the hero of Gaelic Ireland. Ulster was the last stronghold of the Celtic order which the State had determined to extirpate, and the northerners had always been the proudest and most warlike of the Irish, and when, therefore, under the new shiring order, a sheriff was set over Fermanagh it was not long before his "firm" methods drove Maguire into revolt, whereupon this chief was proclaimed traitor.

Red Hugh was naturally for Maguire, but it was uncertain what part Hugh O'Neill, now earl of Tyrone, would take. He, too, had to fear the extension of "English order," which would menace his hereditary lordship; he resented the religious and civil oppression of his country, and when, finally, he threw in his lot with O'Donnell, in 1594, the Government had to face the greatest opponent and the most formidable rising it had yet met. Tyrone and O'Donnell talked mainly of their ancestral rights and of religious tolerance, but at the same time they wrote to Philip asking for 6,000 men, and begging that an archduke might be sent as king.

Finally, the victory of the Blackwater, in Aug. 1598, over Marshal Bagenal, made O'Neill a hero of the Counter-Reformation. While Red Hugh overran Connacht, Tyrone descended into Munster, the new colony vanished like a dream, and a league of Irish and Old English, under James Fitzgerald, the so-called *sugan* (straw-rope) earl of Desmond, took the field. In 1600 the insurgents throughout all Ireland were reckoned at nearly 20,000, but O'Neill knew they could not take cities or hold the sea without Spanish aid.

After the failure of Essex in 1599, Charles Blount, Lord Mountjoy, proved the Scipio to the Irish Hannibal, and the tide was turned less by battles than by devastation and massacre. At last Don Juan d'Aguila arrived with 4,000 men, the Ulster chiefs marched to meet him, and the issue was decided at Kinsale. A rash attack by O'Donnell ended in the rout of the Irish, D'Aguila surrendered, O'Donnell sailing to Spain for more aid, died there, and O'Neill cut his way back to the North. Finally, he submitted to Mountjoy in April 1603, and going over to court was pardoned and restored by the new monarch, James, while Rory O'Donnell, brother of Hugh, was created earl of Tyrconnell.

With this fight Celtic and Norman Ireland passed. A new Irish nationality had emerged, Catholic by conviction, a blend of English and Irish in race, and in the upper ranks, English-speaking. How to reconcile this with a Protestant Government was the problem.

James I., 1603-25.—On the religious question the policy of James was a guarded toleration in the spirit of "*quieta non movere*." The royal prerogative was still supreme, especially in Ireland, and a series of viceroys, such as Chichester (1605-15), exercised it in the interests of that large majority which it seemed now almost hopeless to convert. The opposition of the Catholic party, led by "the lords of the Pale," and the lawyers, was constitutional and loyal; it was impossible to debar "Recusants" from parliament, even if the oath of supremacy barred them from government, and in the older towns this party was so strong that up to 1624 every one had a Catholic mayor. Could James and this moderate element have had their way all might have been well, but the ultramontane spirit on one hand and the Puritan on the other made plain sailing difficult. The Established Church in Ireland was for "strong measures," and, on the other hand, when James proposed a simple oath of allegiance for Recusants, by which they should repudiate the supposed right of the papacy to depose heretic kings, two papal briefs in 1606 declared the proposed oath unlawful for Catholics.

Roman opposition also made the success of the new university at Dublin, founded by Elizabeth in 1591, but a partial one. A centre of disinterested learning would have been a force for reconciliation; but that it was not so intended became the general belief, and it was spoken of as "the college of the heretics near Dublin," and though at first there were no tests, Catholics preferred to seek education abroad. The statutes of Archbishop Laud confined its advantages to members of the Established Church, and though a few Catholics frequented it, disabling tests till 1793 barred them

from fellowships and degrees. As an active centre of learning, however, Trinity college could not fail to illuminate the country which it belonged to and from which it was richly endowed.

The Plantation of Ulster.—Though the earls of Tyrone and Tyrconnell had been restored in 1603, their new position was full of difficulties, for Ulster was now shireland, subject to sheriffs and garrisons hateful to its ancient lords, and Tyrone, involved in disputes with bishops, officials, grantees and his former vassals, complained that strong forces at Dublin were against him. At last the aged chieftain resolved to quit the field. Whether he and O'Donnell were guilty of plots to raise a new rebellion cannot be proved. In Sept. 1607, along with Tyrconnell and nearly 100 more chiefs of the North, he left Ireland for ever. The "flight of the earls" was a mortal blow to the Catholic interest and the old Gaelic tradition. Celtic Ulster was now to become the most British of the provinces, and the lament of the Four Masters over the passing of the earls is indeed the swan-song of the Gaelic world. With these devoted scholars, who laid down their pens in 1616, were silenced also the voices of the Gaelic brehons, poets and historians, and by 1700 only the Irish language, which the gentry were then forsaking, remained a visible memorial of a world that went back 2,000 years.

A plantation of Ireland was now urged on the ground that, without a strong Protestant population, neither would the State be safe nor the State Church have congregations. The earls and their adherents were found guilty of treason, and by legal processes six counties were declared "escheated." By the final plan (1609) the escheated lands were divided between undertakers, servitors, and "natives." Undertakers, mainly English, were to lease only to English and Scottish tenants, and take the oath of supremacy. Servitors, mainly Scots, might take Irish tenants, but if so their rents to the Crown were increased. Native Irish grantees were to pay quit-rents twice as large as the undertakers, but need not take the oath. Of these a good number received grants of thousands of acres, and several junior branches of the O'Neills and Magennis, etc., survived as large landlords, though no longer as "Irish chiefs." But the colonists entered upon the best lands, and the lesser ranks of Irish were reduced to the position of tenants-at-will, for Sir John Davies, the solicitor-general, found, by a most iniquitous decision, that they had had no freehold rights under their attained lords. The town of Derry was given to the City of London, and the London companies received grants which gave them practically all that county.

The practical success of the plantation was great, and for the first time a large part of Ireland was not merely owned by Saxon landlords, but was tilled and farmed by Scottish and Protestant farmers. The Irish population were numerous in the mountainous parts, and their natural disaffection was kept alive by hopes that Tyrone or another would return, but on the surface, at least, they seemed no longer a danger. (See also PLANTATION.)

The success of the Ulster scheme led to plantations in North Wexford, Longford, Leitrim and elsewhere, where, though the natives were treated with more equity, again the object of the Crown lawyers was to find that most of the Irish were not freeholders but tenants-at-will. The new English were dominant; adventurers and speculators such as Boyle, earl of Cork, and other moneyed men, displaced the old aristocracy; 39 new boroughs, carefully rigged, could be counted to offset the old towns, and several of the Old Irish, such as the earl of Thomond, had become Protestant.

In the parliament of 1613-15, summoned by Chichester to ratify the Ulster plantation, the Government engineered a small majority, partly through the new close boroughs, but the minority could claim that they spoke for 21 counties and 28 ancient boroughs in this first general representation of the kingdom. After failing to get their choice as speaker, the Opposition petitioned the Crown, and James saw a deputation of Old English peers and commoners, who complained of religion, the new boroughs, and the rigging of elections. James thoroughly enjoyed himself and declared "What if I had created 40 noblemen and 400 boroughs?—the more the merrier," and, as regards religion, "the pope is your father *in spiritualibus* and I *in temporalibus* only; you are but half-subjects

and therefore only entitled to half privileges." The upshot was that 11 boroughs were disfranchised; James spoke some fair words and continued the *laissez faire* policy on religion, and parliament voted a large subsidy. The Recusants, though called "Old English Irelandized," were, in fact, loyalists with a religious grievance, but they had their left wing, and this veered steadily towards armed protest. The Continent was full of Irish exiles, soldiers and priests, and among these both the Old English and the Old Irish had their heroes. In spite of her troubles, economically Ireland benefited from a period of peace. Agriculture recovered; the settlers brought in their skill and enterprise; and the manufactures started by men like the earl of Cork made Ireland something of an industrial country.

Charles I., 1625-49.—With the second Stuart came the idea of raising men and money in return for religious concessions. The deputy, Falkland, was allowed by "the Graces" to promise various concessions, such as that Catholics might practise at the bar, and that where land-titles, like those of the Connacht gentry under the Composition of Connacht, were lacking in legal confirmation 60 years' possession was to be held good against the Crown. From agents of the Catholic party Falkland secured a pledge of subsidies amounting to £120,000. But when the agents reached London they found a strong anti-papist spirit there, under pressure of which Charles gave way. He dropped the "Graces" but exacted the subsidies, though no parliament was called to ratify them.

To make Ireland first prosperous and then to use her in the royal interest against Puritan opposition was the idea of Wentworth, later earl of Strafford, viceroy from 1633 to 1640. He set himself to break the power of the great and the monopolists, making the Court of Castle Chamber into a Star Chamber for Ireland. While he wrested power from the anti-Irish clique in Dublin, he had no sympathy with Irish or Catholic complaints, and looked on religious concessions merely as policy. Similarly, his aim in making Ireland rich and prosperous was that out of a surplus revenue he might enrich his royal master, and the first-rate army that he raised largely from Catholics and natives was destined, if need be, to serve in Britain. Among the strongest measures of this satrap were the extracting subsidies of £50,000 from parliament, and then denying all but the least important of the "Graces," forcing the juries of Connacht to find a title there for the king, with a view to a fresh plantation, and attacking the London companies. But the policy of "Thorough" ultimately failed, and when Strafford was assailed in England all the interests he had offended in Ireland joined in the general impeachment that brought him to the scaffold in May 1641. His army was disbanded and the control of the Government passed under Puritan lords justices.

The War in Ireland, 1641-49.—A rising in Ulster was inevitable. The Irish there had local leaders of the old stock, such as Sir Phelim O'Neill, and still more abroad, where Owen Roe O'Neill, nephew of Tyrone, was in Spanish service. In the South the native party found a leader in Rory O'More, who planned a union of Old English with their religious grievances, and the Irish who had lost vast estates. A plot to seize Dublin Castle failed, but the rising in Ulster was general (Oct. 1641) and thousands of colonists were murdered, died of ill-treatment, or fled.

For the suppression of "the Irish war," the English parliament at once voted an army, but in order to find the money offered to the adventurers or subscribers of £1,000,000 the pledge of two and a half million acres of profitable lands which were to be confiscated. Naturally, the dread of confiscation, coupled with a belief that the Puritans meant to extirpate their religion, drove more and more Irish into arms. A Catholic confederacy was formed at Kilkenny in May 1642 "to defend religion and the king against sectaries, and establish the Catholic religion as fully as at any time since Henry VII." and soon after Preston and Owen Roe arrived from abroad, the first to lead the confederates, and the second the Ulster forces.

The history of the next seven years is a complicated one. There were forces for the parliament in Ulster and the south, Scots under Monroe in the north-east, an Ulster army under O'Neill, the confederates in Leinster, and Protestant loyalists under Charles' lieutenant-general, James, marquess of Ormonde. As Charles'

cause declined, he offered the confederates terms hardly meant to be kept, and while a moderate party at Kilkenny favoured him, an ultramontane party, backed strongly from abroad, preferred foreign aid, and brought in Rinuccini, bishop of Fermo and papal nuncio, in 1645. This Italian priest's intervention stung English opinion into pitiless fury, but for a time his was the stronger party, especially after O'Neill, whom he favoured, defeated Monroe at Benburb in June 1646. The "Ormonde peace" of that year offered the confederates wide concessions, but Charles' cause was already lost and the nuncio's party denounced the peace, so Ormonde, who preferred "to surrender Dublin to English rebels than Irish ones," finally handed the capital over to Col. Jones, commander for the parliament, and left Ireland in 1647. The nuncio departed in Feb. 1649, and, on the execution of the king, Ormonde returned in the hope to rally all Ireland for the young Charles. But in an attempt to recover Dublin he was defeated by Jones, and when Cromwell himself landed as lord-lieutenant for the parliament his victorious campaign broke the back of the Irish resistance, though it lingered on till 1652. O'Neill died in November, and part of the Ulster army, under his nephew, Hugh, gallantly repulsed Oliver at Clonmel, but other armies won little credit and Ormonde left Ireland finally in Dec. 1650.

The Cromwellian Régime.—Ireland had been conquered by an English faction to whom Irish papists were odious, both in race and religion, and she had now to pay for her own conquest. Not only the "adventurers," but the conquering army also were to be paid in Irish land. Under the rule of Fleetwood and by an Act of Settlement at first ten counties were appropriated to soldiers and adventurers and later others were added. The English parliament, which disavowed any intention to "extirpate that whole nation," divided the population into ten classes, of which the first five were excepted from pardon for life or estate and even "Innocents" found it hard to retain more than a portion of their estates. But such a plan involved a removal of the occupiers and by a scheme of transplantation the former landowners with their families and retainers were ordered to move into Connacht, where land was provided for them, generally though not always of inferior quality. The chief effect of the Cromwellian plantation was to impose a new English and Puritan landlordry on Ireland.

Charles II. and James II.—The monarchy was restored in Ireland by the Cromwellians Broghill and Coote, and this gave the keynote to the resettlement. The Irish had lost all at the hands of sectaries and republicans and supposed that theirs would be the favoured side, but the real division was now between English and Irish, and Charles had to say to them "my justice I must afford to you all, but my favour must be placed upon my Protestant subjects." Ormonde as lord-lieutenant made a great fight for his fellow-countrymen, and finally by the English Act of Settlement the Cromwellian party consented to surrender one-third of the lands in dispute, but 5,000 claims were left unheard. Roughly the old proprietors now held one-third of Ireland; in population the Catholics were about 800,000 to 150,000, but in the corporations, parliament and Government they scarcely counted at this time. Much, however, was done to restore Catholics to the corporations, and their numbers and influence steadily grew. The "popish plot" of 1678 brought on a terrorism to which Archbishop Plunkett fell a victim, but on the return of reason toleration was resumed and the Irish later looked back on Charles' reign as a golden age.

In James II. Ireland found a king who could be trusted to restore the faith and might be induced to repeal the detested Act of Settlement. For over a year the earl of Clarendon acted as viceroy, but his royal brother-in-law balanced him by Richard Talbot, whom he created earl of Tyrconnell, an Irishman and Catholic who first as lieutenant-general and then as sole lord deputy increased and remodelled the Irish army, officered it with Catholics, secured the garrisons and admitted his co-religionists into the Council, the corporations, the shrievalty and the highest legal offices. Ireland for a time was truly a Catholic kingdom and Tyrconnell planned an independent parliament to repeal at once the penal laws and the Act of Settlement. From the military point of view his mistake was in not securing Ulster, and so when James' cause collapsed at the end of 1688, though a great Irish army

was in the field, Derry, Enniskillen and other places became cities of refuge for a Protestant population ready to fight for William.

William III.—In March 1689 James himself landed from France, with officers, money and arms from Louis XIV., but no men. Catholic Ireland could provide these in plenty, but only on terms. When James, in May 1689, summoned what was practically a Catholic parliament to Dublin he announced liberty of conscience for all and some relief for sufferers by the Act of Settlement, but parliament totally repealed the hated act and so restored the heirs of those dispossessed since 1641. An act of attainder was passed which included some 2,400 persons supposed to be supporters of the prince of Orange. As for religion, Catholics and Protestants were to pay their tithes to their own clergy.

The successful stand and relief of Derry was a prelude to the wider operations in which first Marshal Schomberg and then William himself landed at the head of professional armies. On the other hand, a French force arrived to help the Irish. The battle of the Boyne was won and lost on July 1, 1690, and James returned to France, leaving the Irish to ruin themselves in his cause. At least the gallantry of Sarsfield and the heroic stand of Limerick illuminated the last fight of Catholic Ireland as a nation in arms. At Aughrim in July 1691 the issue long hung in the balance until the French commander, St. Ruth, fell, and Ginkel carried the hill. Tyrconnell died, and Sarsfield finally capitulated on terms at Limerick on Oct. 13. By "the Articles of Limerick" the Irish Catholics were guaranteed the religious liberty they had enjoyed under Charles II. and all officers in arms and those under their protection in the five western counties covered by the terms were to retain their estates and professions under a simple oath of allegiance "and no other." William was to have the terms ratified by parliament and do his best to get those who had been attainted restored to their estates; this latter clause was omitted in the signed articles but restored by William. Officers and men who would not take the allegiance oath might depart for France; 7,000 did so, and among the flower of the Irish aristocracy who sailed away was Sarsfield. William was a tolerant man and, after all, the Irish had but served the king *de jure*; but he had now to divide his prerogative with parliament, and while he strove to keep the spirit of the treaty, the parliaments of both islands ratified it in less than the letter: Irish opinion has always called it "the violated treaty." The English Whigs meant to keep the Irish Protestants in the saddle and a Test Act of 1691 was extended to Ireland which excluded Catholics from the Dublin parliament. In 1697 this body ratified what remained of the treaty, but William had to drop the "omitted" clause and abandon the stand he had made for justice. Finally, in 1699, the English Houses confirmed the settlement by which some three-quarters of a million acres passed to new owners. Thus the third conquest of Ireland within a century was achieved. The most illustrious names of the Irish nation disappeared from their country by attainder, death or voluntary exile. Those that remained owned only about a seventh of the soil. The middle classes suffered exclusion from the corporations, trades and professions and the penal laws began with acts of the Dublin parliament in 1695 and 1698, which debarred conscientious papists from wearing arms, teaching publicly, and practising the law.

English arms and statutes had given the Protestant ascendancy the title-deeds of Ireland but at the cost of their own political and economic subjection. Under Charles II. English acts had debarred Ireland from the colonial trade and prohibited the import of Irish cattle into England. Now an act of 1699 ruined the export trade in Irish woollens; Ireland retained the provision trade with Europe and America, and William encouraged the linen industry.

The Penal Laws.—The new ascendancy, full of memories of '41 and '89, was bent on treating the Jacobites like a beaten enemy. The land settlement as made under Charles II. and William was final, and Catholic landowners must keep what little they had and no more. The penal code, by which the majority was rendered powerless to rise again, was mainly passed in the years 1702-15. The acts that concerned the landowners forbade them to acquire freehold other than by inheritance or to take leases of more than 31 years at a crushing rent. By the "Gavelling Act" if the eldest son conformed he succeeded to the whole estate, other-

wise it was equally divided, and this, more than anything else, served to extinguish this class, who either conformed or were impoverished by subdivision. The Catholics in general were barred from trades and professions, education, office (great or small), juries, the electoral vote, the right to arms and a horse.

Feeling against the Presbyterians of the North was hardly less strong in the Episcopalian ascendancy. A Test Act was passed against them in 1703, but after the accession of George I. the "Regium Donum" was restored to their ministers and a Toleration Act allowed them to worship freely and hold petty offices. Though this Protestant democracy was debarred from parliament and from the government of the country, their lot could not be compared in severity to that of the papists, with whom, however, they shared the grievance of riches paid to a Church they both detested.

George I. and II.—With the Hanoverian succession the last hopes of the Jacobites faded away. For the old Irish nation the next half century was a time of oppression, despair and decay: the great exodus of the gentry and the more adventurous spirits to join the Continental armies was balanced by emigration of the poorer Protestants ruined by heavy rents and the commercial acts. The penal laws steadily crushed the upper classes and by 1780 some 4,000 of them had conformed. The old landlords had been the protectors of the Gaelic poets and scholars and naturally as they decayed or joined the ascendancy the old native culture declined, but a new race of poets took the place of the old aristocratic *literati*, using popular language and sharing the lives of the peasantry. Such histories as Lecky's, however excellent on Anglo-Ireland, fail to discern the strong current that ran, half underground, among the Gaelic-speaking people of poetic memories and hopes for a future in which now the Stuarts, now the French, would come over to restore "the Dark Rosaleen." Such feelings were not merely poetic; they were kept alive by unjust laws and what was perhaps the worst land-system anywhere in Europe. Hence those embittered agrarian movements of the "Whiteboys" and the like, which were not all confined to the Catholic peasantry.

The Protestant ascendancy of Ireland now began to resent their political and economic subjection to English interests. The constitutional and legal benefits of "the glorious revolution" had not been extended to Ireland, and while in England the sovereignty of parliament had been established, that of Ireland was shackled by Poynings' law; ministers were responsible only to England, and in 1719 by the Declaratory Act the imperial parliament affirmed its right to legislate for the sister island. The Dublin legislature became a mere dependency, hardly representative even of the Anglican minority.

How to keep Ireland at once dependent and secure was a question the Imperial Government solved for 50 years by putting power successively into the hands of such men as Archbishops Boulter and Stone, both Englishmen, who "managed" the country in the "English interest." The régime had its merits; government was cheaply run, the national debt kept low, and the surplus revenue used to beautify Dublin and develop the country. Economic progress made itself visible, an influential class of rich Catholic merchants appeared, and the wane of Protestant bigotry on the one hand and the ultramontane spirit on the other made toleration possible.

The "Patriot" Movement, 1760-82.—A political party now appeared among the Protestants, inspired by Locke, Molyneux, Swift and Berkeley, which found its leaders in Flood and Grattan. On the other hand, the British Government was ready to make concessions. The viceroy Townshend (1767-72) was instructed to offer an Octennial bill limiting the duration of parliament, and Harcourt continued the policy with the purpose of procuring troops from Ireland for the American War. After Saratoga, the "restrictive acts" had to go; at the same time the Imperial Government encouraged the Irish Protestants to relax the penal code and in 1778 the Catholics were allowed on a simple form of oath drawn up by the Catholic Association to inherit land and take leases like Protestants, while the "Gavelling Act" was repealed. The events of the American War put Ireland for the first time into Irish hands, but now it was a "Protestant nation," and 80,000 volunteers raised under Charlemont boasted

themselves "the armed property of the nation." Free trade with the colonies was won by Flood, and Grattan moved the famous declaration: "no power on earth but the king, lords and commons of Ireland is competent to bind Ireland." The volunteer convention at Dungannon emphasized these demands and the view was general that without legislative autonomy there was no security for Irish rights. The Imperial Government gave way and an act of the Irish parliament was confirmed, amending Poynings' law and providing that bills duly enacted and sent to England should be returned without alteration under the great seal and receive the viceroy's assent. At the same time the Test Act for Protestant Dissenters was repealed and by Gardiner's Relief bill of 1782 Catholics were allowed to purchase lands freely and have their own schools.

The Irish Constitution 1782-1800.—The "Constitution of 1782" was completed by the Renunciation Act of the next year, by which England admitted the claim of the people of Ireland to be bound only by their own laws and courts. But Irish ministers were still appointed by and were responsible to the imperial authority; they could not be turned out by vote of the majority, and though Fitzgibbon and the rest were Irishmen, Grattan, Flood and their party remained a mere Opposition, and legislative autonomy without responsible government and electoral reform proved vain.

Popular support was needed for the new constitution and Flood and Charlemont sought it in a reform bill which would have created a Protestant democracy, while Grattan aimed at an extension of the franchise to Catholics and the admission of their gentry to parliament. But both were thwarted by the narrow clique which under Fitzgibbon (Lord Clare) controlled the Government and resisted pressure alike from Ireland and England. Pitt's attempt to carry a commercial treaty and the Regency dispute emphasized the difficulties created by the constitution, but it might have survived long (for Ireland as a result of commercial freedom, bounties and Foster's corn law was progressing rapidly in wealth, manufactures and agriculture), had not the war with France brought on a situation which grew ever tenser. "French principles" spread among the Presbyterians, the Catholic Association passed into the hands of bold politicians and agrarian discontent vented itself in the "Defenders." Clare held that either the Protestant ascendancy must remain intact or give way to a union, for general enfranchisement would fill parliament with disloyal Dissenters and Catholics and imperil the imperial connection. The British Government preferred Catholic relief to reform, but finally, faced with the question of how to hold Ireland against the French menace, Pitt chose to buttress up the unreformed Irish House which Clare and Beresford could "manage," and after 1798 decided on a union. The approaching crisis was accentuated in 1795 when, after British pressure had compelled the Irish Government in 1793 to admit Catholics to the electoral franchise, the viceroy, Fitzwilliam, failed to carry final emancipation and to break the Clare-Beresford junta. The "Society of United Irishmen," formed originally by Wolfe Tone on constitutional lines, now became revolutionary and entered into negotiations with France for an Irish republic, while the founding of the Orange Society intensified the religious feud. Insurrection acts and the suspension of *habeas corpus* bridled a country which was becoming an armed camp and the peril of a French invasion had to be faced. The Brest expedition of 1796 and that of Bantry bay in 1797 both failed, but Tone still hoped for foreign aid, and a determined French invasion would undoubtedly have set Ireland ablaze. The Ulster Presbyterians were more feared by the authorities than was the Catholic south, and when in 1797 Gen. Lake "disarmed the North" by the most savage methods the back of a national rising was broken. The military forces were small, but 30,000 yeomanry led by the gentry sufficed to break the rebellion when it came. It was but a partial one, for the Government had seized the leaders, and though June 1798 witnessed a Presbyterian rising in Down and Antrim and a far more dangerous one of the Catholic peasantry in Wexford, both failed, and Tone, surrendering with the "Hoche," ended his life by his own hand in prison.

After "ninety-eight" the Union was inevitable. Many of the ascendancy became convinced that only such a measure could save them from the Catholic-Jacobin majority; the Presbyterians were disillusioned by the events of the rebellion and the Catholic population had been cowed into submission. Pitt and his Irish agents, Clare, Castlereagh and Cornwallis, had effective arguments for all—the Catholics could only be sure of emancipation from the Imperial Assembly, only union could save the Protestant establishment, and free trade would compensate the commercial classes. Several Catholic bishops declared for union in the inspired belief that emancipation would follow it, but it is very doubtful how far they spoke for their whole people. There was little to fear from the Irish parliament, where the majority was corrupt and unrepresentative, where the ministry could survive defeat after defeat and where patronage and bribery were at the Government's disposal. Grattan and the poor remnant of "the patriots" made a brave fight, but the Union became law by acts of both parliaments in May 1800.

Thus ended the experiment of a "Protestant Irish nation." The ascendancy created by the revolutions of the 17th century had ruled their fellow-countrymen firmly rather than generously, but in their later stages at least they contributed noble names to the annals of literature, thought, political idealism and religious freedom. They made Dublin a city of noble buildings, and modern Irish civilization is almost entirely their memorial.

THE UNION, 1800-1921

The fiscal fusion of the two islands was not complete until (1) the two exchequers were united in 1817 and (2) a tariff of 10% in favour of Irish industries disappeared in 1821 and (3) the two currencies were amalgamated in 1821. From 1817 the taxation in the two countries was the same, subject to certain exemptions and abatements in favour of Ireland which at one time were not inconsiderable but which had almost ceased in 1921, when the Union was dissolved.

The allegation that Ireland was overtaxed under the Union is not true. The terms of the agreement embodied in the Act of Union were strictly kept. It may be noted that from 1800 to 1817 Ireland paid nothing for Imperial services; that from 1817 to 1877, according to the estimate of a competent authority (J. G. Mulhall, writing in the *Contemporary Review* in 1882) the yield from Ireland did not exceed the cost of Irish services by more than £500,000 a year; and that in the opinion of the late John E. Redmond, speaking in parliament in 1912, Ireland was run at a loss from 1886 onwards. Taking the whole period from 1800 to 1914, the surplus of Ireland's revenue over Irish expenditure was small, probably much less than £1,000,000 a year on an average. For this sum Ireland was defended and had all the advantages, consular and otherwise, of the British empire. From 1914 to 1921 war taxation brought a considerable surplus which in its peak year came to £25 millions.

Condition of Ireland in 1800.—The population, which in 1800 was 4,500,000, was composed of several elements, whose violent discords are at least intelligible:—the Catholic Irish, numbering 3,150,000; the Protestant Anglo-Irish, numbering 450,000; the Presbyterian Scoto-Irish, numbering nearly 900,000, with a small sprinkling of Methodists and other dissenters. The Anglo-Irish were at the top of the social ladder. They comprised the landlords, the official classes, the bishops and the clergy of the Protestant State Church, the few large farmers and the retinue of an aristocratic establishment. The Scoto-Irish were the business men and farmers of the north-east corner. With few exceptions, the Irish Catholics were the peasants and labourers of the country.

The few industries that existed were of no considerable character. The chief of these were the brewing industry, the output of which was about 500,000 barrels a year; the distilling industry, with an output of 4,000,000 gallons; and the cotton industry, which employed some 13,500 hands. Irish exports in 1800 were valued at £5,650,853; imports at £5,275,063. The population of Dublin was 172,000, and of Belfast 25,000.

The condition of the land workers, who formed the great bulk of the population, was in general deplorable. When the population was more scanty, the land was mostly parcelled out in large grazing farms, occupied by Anglo-Irish Protestant farmers. The pressure of population and the stimulus given to tillage by an Irish corn law of 1784 led to the breaking up of the old ranches and to the conversion of the grazier into a middle landlord. The small tillage farmer thus created had little capital or knowledge, and his standard of living was not much higher than that of the cottiers whom he employed. The rent roll of the country was about

ten millions, which was about the average until 1881, when the first great Land Act started the process of reducing rents. The relations between landlord and tenant were of a most unhappy kind. The Protestants had a monopoly of every office. A Catholic could not be a member of parliament; or a king's counsel or a judge—not to mention other positions. Tithes, amounting to about £500,000 a year, were exacted for the upkeep of a State Church for a small minority of the people. The burden of the tithes fell upon the tillagers, who were almost all Catholics.

Catholic Emancipation.—Pitt gained the support of most—and perhaps all—of the Catholic bishops and of many responsible Catholic laymen by promising to do his best to remove Catholic disabilities. The king was bitterly hostile, and Pitt resigned in 1801, to take office, however, again in 1804. Irish Catholics conceived they had been tricked, and the situation was much worsened. The Robert Emmet rebellion of 1803, though of no consequence in itself—for it was little more than a Dublin street riot—indicated the growth of popular resentment. It is not without interest that Grattan severely condemned this rebellion and that Daniel O'Connell armed himself to help to put it down. Henry Grattan, who in the Irish parliament had been the foremost advocate of the Catholic claims, became a member for an English constituency in 1805 and devoted himself till his death (1821) to the championship of the Catholic claims at Westminster. Also in 1805, a Catholic Association was formed in Dublin and was joined by Daniel O'Connell, a young barrister who believed in mass agitation in the country. In parliament, Grattan's eloquence made considerable way. In the five parliaments from 1807 to 1829—1807, 1812, 1818, 1820 and 1826—with one exception, the House of Commons showed a majority for the Catholic cause. But it was a great movement inaugurated by O'Connell in 1823 that carried the day. The country was brought to the verge of a revolution, and in face of this demonstration of popular feeling, an act was passed in 1829 which removed the main Catholic disabilities.

O'Connell, who entered the British parliament as member for Clare, then turned his attention to the repeal of the Act of Union. He attempted the same methods as were successful in the Catholic Emancipation campaign. A vast organization was established; great meetings were called, at one of which, held at Tara, the seat of the Ard-Righ, the Irish newspapers put the numbers present at 500,000. But O'Connell misjudged the forces against him. A later meeting called in 1843 at Clontarf, the site of the battle in which Brian Boru defeated the Danes, was proclaimed. O'Connell was prosecuted for sedition, convicted and sent to prison, but was released through an appeal to the House of Lords. He died in 1847.

Growth of Population and the Famine.—While these agitations were being conducted with such vigour, Ireland in many respects was making progress. Her exports and imports increased from £10,000,000 in 1800 to £40,000,000 in 1840; the excise revenue from £475,000 in 1800 to more than £2,000,000 in 1840. Commerce had increased, agriculture had improved, and the value of land had risen. Grinding, malting, brewing and distilling had greatly increased, while there was a thriving linen manufacture and linen trade. These signs of manufacturing and commercial growth more than outbalanced the disappearance of some small industries which, in Ireland as well as elsewhere, found it impossible to stand the competition of the large scale concerns.

The real troubles of Ireland, however, arose from an increase of population which far outstripped production. The population in 1700 was only 1,250,000. It was 4,500,000 in 1800, and this rapid rate of increase continued for nearly the first half of the 19th century. Early marriage was encouraged, and emigration was denounced. Irish political leaders favoured the subdivision of holdings, contrary to the policy of all British Governments, which sought, by various pieces of legislation, to keep the process within reasonable bounds. The corn laws which, until 1846, put a heavy bounty upon the production of corn tended to increase tillage and to stimulate population increase. The population grew to 8,175,124 in 1841. In that year, the population density of Ireland per sq.m. was 251; England and Wales, 272. There were 685,000

farms in all. Of these, 300,000 were under 3 ac. in extent; and 250,000 were from 3 to 15 ac. As might be expected, the conditions of the vast majority of land workers was miserable.

The potato blight appeared in North America in 1844; it reached Europe in 1845, attacking Belgium, Hungary, Germany, Holland, and the United Kingdom. The United Kingdom felt its worst effects, scarcely a district escaping. 1846 and 1847—especially the latter—were its worst years. In a few weeks the abundant potato harvests in Ireland became a waste of putrifying vegetation. The British Government took active measures to relieve the distress. Relief works were instituted on a large scale, and great doles of maize were given out. In 1846, as many as 285,000 hands were employed on relief works and in 1847, 734,000. The Government imported in the first six months of 1847, 2,849,508 quarters of maize worth, at then current prices, nearly £9,000,000, a great part of which was distributed gratis. The United States sent substantial supplies across the Atlantic. Nevertheless, there were many deaths from sheer starvation, totalling from 1841 to 1851, 21,770. The total Irish mortality for the five years that ended in 1851 was close upon a million. In the decade that followed 1847 more than 1,500,000 persons emigrated.

The famine was followed by the Young Ireland rebellion of 1848. The chiefs of the Young Ireland movement were men of lofty idealism and considerable intellectual attainments. But they were not practical men of affairs and, with little or no previous preparation, they started an insurrection in Tipperary in the hopes that an unorganized peasantry would rise to support it. In the result, some 30 rebels were fired on by a squad of constabulary and fled, leaving some dead and wounded behind. A remarkable temperance movement in 1849 is an interesting study in national psychology. Inaugurated by Father Mathew, it brought down the consumption of spirits from 12,000,000 to 5,000,000 gallons. The movement collapsed with Father Mathew's death in 1856.

The tithe was a burning question until 1838 and many bloody conflicts had taken place in the collection of it. In 1838 the tithes were converted into a rent charge payable by the landlords, and in 1868 the Irish State Church was disestablished.

Land Reform.—An agitation which commenced with the formation in 1850 of an association demanding "the three F's"—Fair rent, Free sale, Fixity of tenure—pursued its inevitable course until it finally extinguished landlordism altogether. An act of 1870 gave a tenant a right to compensation for disturbance and for improvements if, without fault on his part, he was evicted. A world wide depression in agriculture combined with three wretched harvests (1877-8-9) brought about the great Land Act of 1881 which conceded "the three F's." This law and amending statutes of 1887, 1891, and 1896 had the effect of lopping upwards of £2,000,000 a year off the landlords' rental. The real solution, however, was begun in 1885, when the first great Land Purchase Act was passed. Under that act when a landlord and a tenant agreed upon the purchase price of the landlord's interest, the State would advance the money to finance the transaction and would be re-paid by annuities for a period of years. Thus, on a farm rented at £50, if the landlord agreed to sell at 18 years' purchase (which was in general the normal figure), that is at £900, the State would pay the landlord that amount; the tenant would repay the State by annual instalments of 4% or £36 a year; these instalments would cease in 49 years. Other laws were passed, under one of which the State undertook to provide a bonus to help the transaction—this bonus in certain cases amounting to 12% of the purchase money. In 1921, when the Irish treaty was signed, about two-thirds of the land in Ireland had passed to the tenants under voluntary transactions of this sort. The remainder has since been transferred by one great compulsory statute.

This great reform was not achieved without much agitation in parliament and outside it, and much crime. In the worst years, 1877-80, to use the words of a historian of the period, "it rained outrages." It is however, usually forgotten that the real land problem was not the landlord and tenant problem, but the multiplication of small farms and the congestion of the people upon them. In 1881, there were about 600,000 farmers, giving an average of about 30 ac. of cultivable land.

The Home Rule Movement.—The misery of the people gave great strength to the secession from England movement. Propagandists in the '30s announced that under a home Government with power to impose tariffs, Ireland instead of having a population of 8,000,000, as the figure then was, of destitute people, would support a very much larger population (put by some at 25,000,000) in comfort if not affluence. Similar arguments were used by the leaders in the Home Rule movement (1870-1916) and the Sinn Féin movement (about 1900 to 1921). Arthur Griffith, the founder of the latter movement, put Ireland's true population at 20,000,000. The contrast between their actual position and their potential position under a Dublin parliament inflamed the people, instilled in them a hatred of Westminster rule, and kept them steady in the struggle for political independence.

That struggle took two forms. From the formation by Isaac Butt of the Home Rule party in 1870 down to the rebellion of 1916, it was mainly constitutional. But side by side with the constitutional movement, the physical force men kept up their secret associations for the establishment of an Irish republic, and now and then broke cover in violence of one sort or another. The most extreme Irish revolutionaries were in the United States of America, where the Fenian association was formed in 1863. (*See FENIANS.*) Irish-American newspapers founded a skirmishing fund in 1880, one of the objects of which was openly stated to be the burning down of London on a windy night. This extreme section were responsible for a petty attempt at a rebellion in Dublin and Kerry in 1867, and for the Phoenix Park murder in 1882 of Cavendish and Burke, the chief secretary and under secretary for Ireland. In the main, however, the physical force men were content, while advocating violence if opportunity should permit, to give adherence to the constitutional Home Rule movement which aimed at legislative and administrative control of Ireland by Irishmen themselves, without entirely severing the imperial link.

Butt's Home Rule Association for a time made little headway, and a Home Rule bill introduced by its leader in 1874 found only eight supporters in the House of Commons. The driving force of the movement came with the establishment of the Land League by Michael Davitt in 1879, which became a secession-cum-agrarian movement, under the leadership of an impoverished Irish squire, Charles Stewart Parnell. The Land League dominated the country and boycotting of farmers and shopkeepers who were not prepared to obey it proceeded on an extensive scale. Strong counter measures were adopted by the Government, under one of which the executive were empowered to put and keep in jail as "suspects" any person at their discretion. Parnell and many of his followers were imprisoned under this drastic code.

Ultimately Gladstone sought to solve the Irish problem by his Home Rule bill of 1886. It was a very modest measure, which transferred Irish administration to an executive appointed by an Irish parliament, but left most of the taxing power at Westminster. It was, however, accepted by Parnell as a settlement; though he fully recognized, to use his own language, that it set up a "subordinate parliament." Such as it was, it met with a furious opposition both in England and in Ulster. Many of Gladstone's followers seceded from him. Ulster threatened violent resistance. The bill was rejected in the House of Commons by 343 to 313. The situation was further complicated by the law case of O'Shea v. O'Shea and Parnell a divorce petition in which Captain O'Shea, an Irish member of parliament, alleged adultery between his wife and Parnell. The facts were clear and a divorce was granted (Nov. 15, 1890). The heads of the Catholic Church in Ireland called for Parnell's retirement. He refused, and his hitherto united party was split into two factions. The breach was not healed by Parnell's death (Oct. 7, 1891).

In 1893 Gladstone, again in office, introduced a Home Rule bill which passed the Commons (301 to 267) but was rejected in the Lords by an overwhelming majority (419 to 41). Another attempt to settle the question was made by the Irish Council bill of 1907, which was intended to establish a purely Irish body to spend in Ireland the proceeds of Irish taxation. This bill, however, was unacceptable to the Irish people and was withdrawn. H. H.

Asquith introduced his Home Rule bill in 1912. It passed the House of Commons in Jan. 1913 (367 to 267) and was rejected by the Lords. The bill included Ulster and if passed again in three successive sessions by the House of Commons, would automatically, pursuant to the provisions of the Parliament Act 1911, become law without the assent of the House of Lords. Ulster prepared to resist it, and the Ulster Volunteers, headed by Sir Edward (Lord) Carson, aided and abetted by many prominent men in both countries, armed themselves and undertook to set up a separate Government in Belfast should the bill become law. The bill passed the House of Commons in May, 1914; the Lords excluded Ulster; an attempt at accommodation by the king at a conference held in July failed. The outbreak of war altered the whole situation. The bill, without resistance, passed and became law for all Ireland in Sept., 1914, but a contemporaneous act was passed which provided that it should not come into force until after the war, the Government giving an undertaking to bring in a bill dealing with the Ulster situation. The bill never came into operation.

Ireland in 1914.—When the World War came, the position of Ireland was in most respects very satisfactory. The landlord and tenant question, for all practical purposes, had disappeared. The country was free from serious crime. Emigration had brought the population within reasonable limits. The process of *morcellement* that had been the real economic curse of the country, had ceased. Imports in 1913 were valued at £74,000,000; exports at £73,000,000. Comparing the periods 1895-1899 with the year 1913, the average increase in yield per acre was not less than 25%, the additional money value to the country being £15,000,000 per year, and the money value increase in stock on the land was not less than £20,000,000. In 1913 the money on deposit in the Irish banks was £60,000,000 in addition to which the Irish people had large sums of money invested in England.

One of the most important and beneficial statutes ever passed for any country, was the Labourers (Ireland) Act 1883, which enabled comfortable cottages to be built at local expense (aided by a small State subsidy) for agricultural labourers, who received in addition from half an acre to an acre of land as well. The schemes under this act worked so well that Ireland is provided with 50,000 well built cottages which, with the half acre or acre patch adjoining, are let to a labourer at from 8d. to 1/6 a week.

The population was divided according to religious creed as follows:—Catholics 3,242,670; Protestants 576,611; Presbyterians 440,525; Methodists 62,382; Jews 5,148; other persuasions 60,504; indeterminate 2,379. The population of Dublin had increased from 172,000 in 1800 to 304,000 in 1911; that of Belfast in the same period from 25,000 to 386,000.

The position of the Catholics had enormously improved. The primary school system established in 1831, had from the first been a success. An Intermediate Education Act of 1879 which indirectly subsidized intermediate education, was of great and lasting benefit. The national university was founded in 1908 and became substantially a Catholic university. The Local Government Act of 1898 transferred all county power and patronage from the landlord classes, represented by the grand jury, to elected county councils. A strong Catholic middle class had grown up.

Ireland was well equipped with railways, having a mileage of 2,940 miles; in addition to 15 light railways established by State subsidy. There was an admirable judicial system in the country modelled upon the British, but containing features specially adapted to Irish requirements. In the British legislature, Ireland had 103 members while England, Scotland and Wales had 567 all told. The population ratio of Ireland to Great Britain was 1 to 10; while in 1914, taxation was £2. 10. 0 per head of the Irish population and £4. 8. 3. per head of the British population. A Congested Districts Board, set up in 1891 endeavoured to solve the small holding problem by migration and was slowly succeeding. The Department of Agriculture established in 1900, was so admirable that a commission sent over by the Canadian Government to study European agricultural conditions, specially recommended that the Irish model should be followed. The best feature of all was the success of the Irish Agricultural Organization Society,

established by Sir Horace Plunkett in 1889, to organize and educate the farmers in the methods best calculated to increase the production and facilitate the sale of agricultural products and to cheapen the cost of articles used by the farmers.

Rebellion of 1916.—The enrolment of the Ulster Volunteers to resist home rule angered the south of Ireland; the impunity accorded to an unconstitutional and illegal movement emboldened and stimulated the young Home Rulers. A body of "Irish Volunteers" was established in Oct. 1913 under the auspices of John MacNeill, a cultured Gaelic scholar and professor. It attracted to its ranks a number of constitutionalists and such residue of physical force men as were left in the country, and arms were smuggled in. Bad housing and labour conditions in 1913 led to much intimidation, sympathetic strikes and some violence, and produced the Citizen Army, composed of Dublin workers, men and boys, under the leadership of James Larkin and James Connolly.

When the war broke out, Redmond and his parliamentary followers declared unequivocally in favour of the allies, and for a time it seemed as if the whole country was with them. A meeting at the Mansion House, Dublin, on Sept. 25, 1914, at which the prime minister (Asquith), and Redmond, Dillon and other leaders spoke, was packed, and there was much enthusiasm. But the war did not go well; conscription soon had to be introduced in England; and it was put about that Ireland would also be put under the yoke; no Irishman would submit to compulsion to fight; if Germany won, no land purchase annuities would have to be paid; there was land enough for everybody; Sinn Féin pamphlets and newspapers multiplied prodigiously. Still, Ireland raised 134,000 recruits for the war, and the rebellion came as a great surprise.

About this time the Sinn Féin party began to get a little prominence. Founded by Arthur Griffith, a Dublin journalist, in 1900, it bore pretty much the same relation to the Home Rule party under John Redmond as the Young Irelanders bore to the Old Irelanders under O'Connell. Sinn Féin (the best equivalent of which is the French *nous-même*) was not content with the home rule which Redmond was willing to accept and which left the taxing power, for all practical purposes, at Westminster. Sinn Féin wanted a self-contained Ireland, with full taxing power and advocated the building up of a great manufacturing country by a system of tariffs. Culturally, it resented the "anglicization" of Ireland and favoured the revival of the Irish language.

The rebellion was planned by the Citizen Army, and the left wings of the Volunteers and Sinn Féin. But the German aid which had been arranged for did not arrive; the German vessel "Aud" containing the arms for the rebels was captured off the coast of Kerry; and Sir Roger Casement, who came from Germany in a submarine, was taken and later executed. The Volunteers tried to call the rebellion off, but the Citizen Army forced it on and it broke out on Easter Sunday of 1916. The actual fighting, which was chiefly street fighting in Dublin, lasted a week; there were only 2,000 rebels in all engaged. The British troops lost 377, including 106 killed; the rebel losses were trifling. Fifteen rebels, including James Connolly, were executed.

The Government at once set on foot negotiations for an Irish settlement, but these broke down, as also did a convention of Irishmen called under Government sanction which sat in deliberation for nearly a year. Ulster wanted its six counties intact; the Nationalists would not budge an inch on that question. It is probable, however, that the rebel movement would have died down, temporarily at least, had it not been for the introduction in 1918 of the Military Service bill of that year. The measure raised the age for compulsory service to 55 and it applied to Ireland. The country rose against the measure; funds were collected at every Catholic church in the country and a total of £200,000 was gathered. The act was never enforced, but Ireland swung definitely to the left. At the general election of 1918, at which the Sinn Féin party raised the Republican standard, the old Irish party was routed, and 73 Sinn Féiners were elected out of a total Irish representation of 106.

The "Anglo-Irish War."—The 73 met in Dublin, calling them-

selves the Dáil (national assembly), passed a declaration of independence and appointed ministers. But apparently it was no part of the original policy of the Dáil to resort to violence. A new departure was made in Irish politics by Daniel Breen who thought that the best method to clear the British out of the country was to kill off the Irish Constabulary, who were the eyes and ears of Dublin Castle, the seat of Irish Government. The "Anglo-Irish War," which began in Jan. 1919 and ended in May 1921 and which brought about a dominion status for 26 counties of Ireland, is surely one of the strangest episodes in history. Daniel Breen, who occupied the position of track walker on one of the Irish railways, began it, and in his book he tells the story with great frankness. Breen and seven comrades waylaid two Irish policemen in Tipperary and shot them dead (Jan. 1920). The same procedure or procedure somewhat similar was followed in other places. The idea caught on and Michael Collins, who was at one time a postal clerk in London, had crossed to Ireland in 1916, and was engaged in the rebellion of that year, took it up. Soon a process which its supporters call war and its opponents assassination became general.

The various stages of the "Anglo-Irish War" were: (1) the shooting, at rare intervals, of policemen as they moved about a city, town, village or countryside; (2) the like, at more frequent intervals; (3) attacks upon remote and outlying police barracks; abandonment of such barracks; alarm amongst the police and some defections; (4) the advent, in June 1920, of armed men from England to take the place of the police—some called Auxiliaries, to the number of 1,500, and others, from the colour of their clothing, Black-and-Tans, numbering 5,800; (5) a "war" as before, consisting of the shooting of policemen as before; the shooting of civilians engaged in the British service who were suspected of activity in putting down the revolutionary movement; ambushing with bomb or rifle or revolver fire of Auxiliaries, Black-and-Tans, police and sometimes of regular troops; the shooting of persons suspected of giving information to the British forces; the destruction, by arson or other means, of public or private property; the destruction or obstruction of roads and bridges; a general espionage among the lower classes of the community; a collection of moneys by those engaged in the "war" by threats of murder or destruction of property, and the general terrorism of the country.

It has been stated on very good authority that the actual number of gunmen engaged was only 2,000. At first, the great bulk of Irish public opinion was opposed to the guerrilla warfare. But soon its daring, its success and the ingenuity and resource shown in many of its episodes captured the support of the lower orders of the people. A ruthless system of terrorism intimidated responsible people, for no man could safely venture upon a public expression of a hostile opinion. The premises of the *Daily Independent*, which termed an attempt on the Viceroy's life "murder," were burned to the ground, and every newspaper in Ireland knew right well that a like measure would be dealt out to it in similar circumstances. The counter-terrorism and activities of the Black-and-Tans greatly helped the revolutionaries, for they created a hatred of British rule where it did not exist before and strengthened it where it did. But it was not till the "war" was coming to an end that the Dáil (March 1921) purported to ratify it.

The Irish Catholic bishops in secret sessions were of opinion that the "war" was not morally justified and some of them openly said so, but there was no public expression of opinion from the episcopal bench as a whole. The morality of the "war," however, was upheld by many if not most of the other Catholic clergy.

As the result of the activities of the Black-and-Tans and Auxiliaries the houses of those suspected of being revolutionaries were destroyed, besides many creameries. A great portion of the city of Cork was burned down by the regular military by way of revenge for some outrages committed upon them. Many murders of real or supposed revolutionaries were committed. There was a competition in crime.

The British Government winked at these performances. It even encouraged them. The *Weekly Summary*, an organ printed and published by the authorities in Dublin Castle, was a direct incitement to murder. "British rule became a byword and a scoff

in every country in Europe and across the Atlantic" (letter of Rev. D. C. MacGregor, Moderator of the Presbyterian Church of England to the *Times*, March 5, 1921). Public opinion in England was deeply stirred, and formed its expression in vehement denunciations of Black-and-Tan terrorism by many public men, foremost of whom was the archbishop of Canterbury. The events in the south of Ireland had their repercussion in the violent religious disturbances in the north. From July 1920 to June 1922 the city of Belfast was the scene of many shocking murders.

Soon after the beginning of the "war," the cabinet introduced and passed the Home Rule Act, 1920, which divided Ireland, for political purposes, into two areas, namely (1) six counties carved out of Ulster and (2) the other the remaining 26 counties. The statute, while transferring the administration of Ireland, north and south to Irish hands, left the great bulk of the taxing powers in the control of the British parliament. The passing of the measure rather aggravated the situation than otherwise, so far as the south was concerned. The six-counties parliament, however, was duly established.

The growing pressure of English public opinion was the principal factor that induced Lloyd George and his cabinet to enter into negotiations with E. De Valera, then the president of the Dáil. A time was arranged (July 1921) and the Anglo-Irish treaty, which was confirmed by the British parliament and by the Dáil, was entered into in Dec. 1921.

The treaty gave Ireland the political status of the dominion of Canada, with liberty, however, to the Ulster parliament to opt out of the measure. The new dominion was to be called the Irish Free State. Certain harbour and other facilities were reserved to Great Britain, and provision for other facilities in time of war or of strained relations with a foreign power. If Ulster opted out, a commission, consisting of one representative of the Irish Free State, one representative of Ulster, and a chairman to be appointed by Great Britain, was to be set up to readjust the boundaries between the six county area and the 26 county area. The treaty provided for the ascertainment by arbitration of the Irish Free State's liability for the national debt.

Ulster did opt out, but objected to the appointment of the boundary-fixing commission, upon the ground, which was wholly untenable, that Ulster was not a party to the treaty. The Free State Government strenuously pressed for the commission, and ultimately a supplementary statute was passed, under which a commission was set up consisting of a representative of Ulster, John MacNeill representing the Irish Free State and a South African judge as chairman. The commission arrived at a finding that was unanimous, and which was not favourable to the Free State. A premature publication of the finding led to a storm in Ireland. For the sake of peace it was agreed that the commission and its findings should be scrapped, and that Great Britain should abandon any claim to an Irish contribution to the national debt.

The Irish Free State, accordingly, started on its way under favourable auspices. It was a rich agricultural community, yielding a national income, as the events proved, of £25,000,000 per year, on the same taxation basis as Great Britain. It had made enormous profits by the war. In 1921 there were nearly £200,000,000 on deposit in Irish banks, nearly £100,000,000 invested in Government securities and over £200,000,000 invested in England or abroad. A proportion of about two-thirds of this may safely be attributed to the Free State. It was an admirably equipped going concern, with excellent railway, telegraph and telephone systems, roads at least up to the European average, a full equipment of buildings, of schools and educational appliances, numerous public buildings, many of which were of great beauty. It was under no obligation to provide its own defence, or to have a single soldier or a single ship of war, or to pay Great Britain, which must always, in the nature of things, provide for its defence, a sixpence for doing so. It had not a farthing of national debt. (For the subsequent history of Ireland see *IRISH FREE STATE AND IRELAND, NORTHERN.*)

ARCHAEOLOGY

Human Inhabitants.—The human occupation of Ireland does not begin until a late date in the history of Europe. The island seems to have been uninhabited by man throughout the whole of the ice age; at least, no trace even of an interglacial colonization has as yet been found anywhere within its borders. The alleged discoveries in Co. Sligo do not modify this statement. While some of the numerous caves in the limestone regions may contain remains of Palaeolithic man, no such discoveries have hitherto been made.

The raised beach at Larne, Islandmagee, and other sites in Co. Antrim, have yielded the oldest relics of man as yet found in Ireland. These have affinities in two directions; they indicate that even at the beginning of human occupation in the country there was a racial admixture. On the one hand, there is a clear association suggested with northern Spain; on the other, there is evidence of influences from north-eastern Europe. The first association is indicated by certain roughly pointed choppers or picks, cognate with the tools of the Asturian type, first brought to notice by Obermaier (*El Hombre Fósil*, 1916, p. 334). The other is suggested by the so-called "Larne celt," a hand-pick which has all the appearance of being a degenerate form of the Campignian pick.

These two civilizations, the Asturian and the Campignian, were contemporary, each in its own region. The Asturian is a very primitive north Spanish and Pyrenean culture, the remains of which, in stratified deposits, overlie the Palaeolithic beds and underlie the Neolithic, and therefore belong to a time intermediate between the two main stone age cultures. The Campignian culture, which is distinguished by the presence of pottery (for the first time in Europe), of picks consisting of bars of flint so chipped as to have a blunt point at each end, and the *tranchet* or kitchen-midden axe (an implement with a bevelled edge, resembling the point of a gigantic turnscrew), extends over the greater part of northern Europe from Denmark (Maglemose and the shore-dwellers' shell-heaps) to France; in the latter country is the typical station of Le Campigny, which has given its name to this phase of civilization. The Campignian is intermediate between the Palaeolithic and the Neolithic cultures.

Thus there was a double immigration into Ireland at the beginning of its time of human occupation: an immigration from Spain, which must have crossed the Bay of Biscay—for the Asturian culture is not found in France—and one from some nearer place in northern Europe—but not from Great Britain, in which country the Campignian is all but completely absent.

As yet nothing but the implements have been found. No human remains have come to light associated with them. Nor are there any known inland sites yielding relics of these two occupations. They must, however, have endured for a considerable time, as the gravels where they are found are stratified to a considerable height, and artifacts are found practically through the entire deposit.

It is improbable that any human bones will ever come to light to tell us about the physical characters of these earliest immigrants. In the damp climate of Ireland the human bones that are found are so decomposed as to be almost useless for scientific purposes. No inland sites existed, because the interior of the country at the time was thickly covered with virgin forests, infested by dangerous wild beasts: and the shore offered a safe and comparatively easy source of sufficient food.

The ultimate fate of these first immigrants is unknown. They

METAL ORNAMENTS AND IMPLEMENTS OF THE BRONZE AGE IN IRELAND

(A) Copper halberd blade, the characteristic weapon of the early bronze age; (B) Gold torque, evidently a neck ring; (C) One of a pair of gold ear rings formed of four flat narrow fillets joined at their inner edges in torque pattern; (D) Gold open ring of the type probably used as currency; (E) Bugle-horn shaped trumpet made in two portions soldered together; (F) Cast trumpet, 34½ inches on concave side, probably used as a speaking trumpet; (G) Circular gold plate or "sun-disc," probably worn on breast; (H) Trumpet, 24 inches along curved edge; (I) Gold lunar or "moon disc" worn around the neck; (J) Copper hatchet, secured to a wooden handle by strings of hide or gut

may have endured to form the bulk, or at least the basis, of the later occupation of the Neolithic period, having learnt the Neolithic arts by way of trade: or else they may have been extinguished by a new immigration, introducing the Neolithic culture. Practically nothing is known but the bare fact of the existence of the Asturian-Campignian settlement.

THE STONE AGE

It becomes increasingly difficult to separate distinctly the Neolithic culture from the culture of the bronze age which followed it. Over the whole continent of Europe objects once classified as Neolithic persisted into the bronze age, if they were not actually introduced in this later period. For two reasons this difficulty is especially acute in Ireland. In the first place, the population was continuous throughout the two stages of culture. There is no racial break at the introduction of bronze, as there is in Great Britain. The latter country was invaded, at the beginning of the bronze age, by the (round-headed) folk commonly known as "The Beaker People": a body of invaders coming from the Rhineland. But beakers are all but unknown and brachycephalic skulls are rare in bronze age Ireland, where there was no change of population; and the bronze culture was introduced gradually, by way of trade.

Again, the stone age in Ireland was seemingly of very short duration. The metal culture must have reached that country considerably earlier than it reached Great Britain. All the archaeological evidence points to the conclusion that Ireland is an island of the Atlantic, Great Britain is an island of the North sea; and that though so close together, they do not therefore form one archipelago. Culture came into Ireland from the south-west, from Spain across the Bay of Biscay. The old connection between Ireland and Spain was maintained for many centuries. One of the most remarkable monuments of this connection is the inscribed slab at Clonfinloch, in the county of Offaly. This is a great flat stone, upon which is a sculpture indistinguishable in style from the Neolithic devices painted on the walls of certain

Spanish caverns. This monument is undoubtedly the record of some sort of connection between the two countries; and we may call it the oldest historical record in northern Europe.

The remains naturally associated with the stone age in Ireland are implements of flint and of other stones, and certain classes of rude stone monuments. Such objects were certainly produced in the stone age: but they continued in use into the bronze age—indeed, flint tools continued in use in the country to an even later date, for in Ireland there is practically no native source of supply of tin, and no reason to believe that such a source ever existed. Tin was a necessary ingredient of bronze, and all the tin used in the country had to be imported from abroad. In consequence it must have been expensive, even if we accept the theory of the late Dr. Bremer, that the tin mines of Cornwall were at first an Irish possession, and were worked by Irish artificers down to the middle of the bronze age. This would account for the early pre-eminence of Ireland in the bronze age civilization, and for Ireland's pre-eminence over Britain in the matter of the introduction of bronze (even although the want of tin in Ireland handicapped that country in the race); it also accounts for the frequent discovery of objects of Irish provenance in Cornwall, and, on the other hand, for the absence thence of definite traces of the Beaker people. On the other hand, the loss of the control of the Cornish mines is the most obvious explanation that can be made of a decline in the prestige of Ireland which we can trace, from the archaeological evidence afforded by the remains of about the middle of the bronze age.

Particulars of the various types of stone implements found in Ireland will be found in the works enumerated in the bibliography (*q.v.*). They correspond with the stone objects of the rest of northern Europe in general, though with certain local differences of detail. Their standard of excellence of workmanship is high on the whole; the knives and arrowheads, formed by chipping over the entire surface of the object, are often real works of art, showing great delicacy of touch on the part of their makers, and appreciation of beauty and symmetry of form. A peculiar type

of lance-head, of a lozenge shape with flat sides and chipped along the edges, is especially characteristic of Ireland, and affords one more link between this country and Spain, where similar weapons are also found.

Rude Stone Monuments.—Ireland is pre-eminently a country of rude stone monuments, some of them of great size. There is a considerable number of stone circles in the country, but on the whole the stones of which they are composed are comparatively small and few in number, though there are some notable examples here and there. On the other hand she possesses some of the most notable dolmens (table-stone monuments) in Europe. There are about 900 dolmens in the country—a large number for so small a region, especially since many must have been destroyed from time to time—but until a satisfactory archaeological survey has been carried out it will be impossible to say how nearly this number approximates to reality. Among the dolmens of Ireland is the great monument at Mt. Browne, near Carlow, whose immense cover-stone, weighing about 100 tons, is surpassed in size only by the cover-stone of one monument in Spain. In the matter of rude stone monuments, also, the affinities of Ireland with Spain are very close.

Gold.—One of the chief determining influences which gave to Ireland its important position during the bronze age was the gold in which at the time the alluvial gravels of certain parts of the present Co. Wicklow must have been very rich. There is no evidence that the parent vein of these deposits was ever discovered: there is no trace of early mining in the region; and indeed the parent vein has never been found, even in modern times. It is probably by now exhausted; gold in commercially remunerative quantities is no longer to be found in the district. But the large number of early gold ornaments found in Ireland prove that in the first stages of the bronze age there was a considerable store of the metal at the disposal of its inhabitants; and the wide dispersal of gold ornaments of Irish provenance over the continent of Europe shows that this metal formed an important material of trade.

The chief gold ornaments that have come down from the early stages of the bronze age are discs of thin gold plate, with a slight geometrical ornament engraved or embossed upon them. These are of Irish origin, wherever found. At a later stage in the bronze age, when Ireland had become a receiver rather than a giver in the matter of culture, the twisted *torque* was introduced—a collar consisting of a bar or ribbon of metal, twisted into a screw and curved into a loop; the ends being drawn out and bent abruptly, so as to hook into one another. Later still, as the bronze age was drawing to its close, a peculiar form of ornament of a problematical kind came into use. This is in the shape of an open ring with the ends terminating in discs, or in expanding solid or hollow conical knobs. Various conjectures have been made as to the use of these objects; one of the most probable is that they were media of currency.

THE BRONZE AGE

Of the bronze implements many types are similar to those found elsewhere in northern Europe, but some have distinctive character. The flat copper hatchet is probably indigenous to the country, from which it spread over the continent. The copper halberds are especially remarkable. They are a kind of dagger-axe, being in essence triangular dagger-blades mounted at right angles at the end of a long handle. Here again there is evident connection with Spain, where this form of weapon reappears. About the middle of the bronze age Ireland seems to have lost her initiative in civilization; the later types of hatchet-heads, etc., are imported into the country, rather than exported abroad. To the last, however, the Irish metallurgists of the bronze age retained their skill and their appreciation of beauty and symmetry; some of the late spear-heads, for example, are of admirable workmanship. For one class of objects Ireland was the source of supply for Europe till the end of the bronze age—the horn-shaped trumpets, made by the *cire perdue* process, which are found in many places on the Continent; there is one represented as lying by the side of the well known statue of the Dying Gaul.

The rude stone monuments show a power of manipulating enormously heavy masses of stone; and as this required the collaboration of a very large number of men, it presupposes no small degree of social organization. The great monuments that appear to have been erected in honour of deceased lords are impressive evidence of the respect in which they were held; such are the Giant's Ring near Belfast and, especially, the tumuli in the ancient royal cemetery on the river Boyne, about 5m. above the town of Drogheda. Of these tumuli, the most noteworthy is the famous mound of New Grange, which covers an acre of ground. It is about 40ft. in height, and encloses a large chamber the walls of which are lined with huge slabs of stone. A passage between 50 and 60ft. in length gives admission to this chamber. Many of the stones used in the construction of the passage and chamber, as well as certain stones of a surrounding kerb outside the mound, are covered with symbolic devices—spirals, lozenges, zigzags, etc., the meaning of which must be a matter of conjecture, as we possess no direct clue to their interpretation. A circle of pillar-stones, the tallest of which is about 8ft. in height, surrounds the mound. The neighbouring mound (called *Dowth*) possesses two independent chambers, the stones of which bear similar ornamentation. To the north of the same county of Meath, near the town of Oldcastle, the Lochcrew hills bear a series of cairns containing similar but smaller chambers, likewise enriched with sculptured symbols; and there are others at Knockmany and Sess Kilgreen in Co. Tyrone, and in the Deerpark of Castle Archdall, Co. Fermanagh.

The few human bones found in Irish bronze age sites indicate that the population of the country during this period belonged to the Mediterranean race (see RACES OF MAN)—a relatively short, dolichocephalic (long-headed) and dark-complexioned people, to be seen to-day in their fullest purity in Spain. This population was apparently dominant all through the stone and bronze ages, for the few skulls of round-headed individuals that have been found are to be taken as those of casual wayfarers. Of the language of this people we are absolutely ignorant. Some of the river names, which cannot be explained with the aid of Celtic, may belong thereto: and a few inscriptions in the Ogham character, found in the Pictish regions of Scotland, may possibly preserve some words of this tongue, or of a cognate dialect. These inscriptions have defied all attempts to decipher them.

Scandinavian and other foreign objects of the late bronze age found in Ireland speak of an oversea trade with eastern and southern Europe; the centre of activity shifted eastward in the course of the bronze age. We may assume that the technical skill displayed by the bronze objects which have survived was likewise shown by the objects in wood and in textiles, which no longer exist. Here, as elsewhere, owing to the decay of organic materials, only a very incomplete picture of ancient civilization can be reconstructed. The bronze age was illiterate, so that no literary documents have survived, even indirectly; though there very likely is a considerable body of bronze age material embedded in the vast body of Irish literary and oral tradition.

THE IRON AGE

The Celtic (Iron Age) Immigration.—This ancient people remained in undisturbed possession of the country down to about 400–350 B.C. It is possible that there were occasional immigrations such as a gold-producing country would naturally attract; but if so these became absorbed in the aboriginal population, and cannot now be isolated. But at the date indicated a much more formidable immigration took place, doubtless only one phase of the movements of peoples in central Europe, of which the Gaulish sack of Rome in 390 B.C. and the attack on Delphi about 100 years later were outstanding incidents. The Celtic people seems to have had its origin in the regions between the head-waters of the Rhine and the Danube. There they developed their peculiar linguistic characteristics, which is the chief if not the only common mark of "Celticity" in the modern world. They seem early to have become acquainted with the iron-smith's craft, and with the aid of their iron weapons they subdued one by one the petty peoples of the area of Europe north of the Alps. Over these peoples they

spread a veneer of Celticity; they Celticized them in speech, in religion, and in organization: but could not make any very great modification in their racial affinities. This explains the racial diversity which underlies the superficial unity of the Celtic peoples, and which makes it difficult to determine to what people the term "Celtic" most fittingly belongs.

A community—or more probably, several communities—of this people effected an entrance into Ireland in or about the middle of the 4th century B.C. They were probably few in numbers; but they had the advantage of a superior military organization, and, especially, of iron weapons. In time they effected a complete revolution in the life of the country. Their Celtic speech completely ousted the aboriginal Pictish. Their Indo-European patriarchal organization took the place of the aboriginal matriarchate. New gods and new methods of government, new arts and new crafts, were introduced. The aborigines were reduced to vassalage, which, though mitigated with the establishment of Christianity, was never completely terminated until conqueror and conquered alike were subdued by the Norman. The newcomers were a tall fair people, of Nordic extraction, and contrasted physically with the aborigines. The contrast was maintained, as we cannot doubt, by restrictions on intermarriage. In the literature which a little later began to come into being, an aristocratic product, the distinction between fair and dark people is of paramount importance. Every person who is spoken of with respect, save for a number of individuals of exceptional character who "prove the rule" much more clearly than in most cases of the kind, is described as being tall and fair, with long flowing locks. Every person who for any reason is spoken of with disdain is described as being short, dark, and with close-cropped hair.

The culture which the newcomers brought into the country belongs to the later stage of the iron culture of Europe, which goes by the name of La Tène. The earlier phase of the iron culture, called by the name of Hallstatt, is not represented in Ireland save by a few stray objects which came in by way of trade or by mere accident, and do not indicate a permanent settlement. This enables us to assign a date to the Celtic invasion with tolerable exactness. The legends of the landing of the invaders, attracted by the country's store of gold, may at least be historical in that they represent the landing as taking place in the south-east corner of the island: the place where the gold-bearing gravels are to be found.

Iron Age Remains.—The actual remains of the pagan iron age in the country are, comparatively speaking, scanty. They include a number of types of bronze objects, some peculiar to Ireland, and several of very problematical use: some spearheads and other objects of iron: and, most remarkable of all, a few large stones, probably sepulchral gravemarks, bearing sculptured ornament of the geometric-floral type associated with the art of the La Tène period. In other respects the pagan iron age was of very great importance in the history of Ireland. At this time the literature began to come into being, though the documents which transmit it to our time are of much later date, and show clear evidence of editorial manipulation. The oldest written relics are the Ogham inscriptions, which preserve early forms of the Irish language not otherwise illustrated. Such of the inscriptions as have been deciphered contain nothing but names, with words denoting relationship linking them together. The Ogham alphabet is a cipher, based upon an abbreviated form of the Roman alphabet, and doubtless originally intended, not for writing at all, but for secret communication by means of the fingers. The letters are combinations of strokes, in number from one to five (representing the fingers) disposed in various positions around a central line. (See OGHAM.)

Probably the majority of the numerous ancient fortifications are also to be reckoned to this period. These are as a rule circular enclosures, surrounded by one, two or three ramparts of earth or of stone. Others, however, are much more complex in their plan. Very little is known of these enclosures, which are common everywhere. Probably some of them are as early as the bronze age; others, certainly, are quite late in date (say A.D. 700–1000) for inscribed stones are used as building material in their construction.

Some are burial-enclosures; some, perhaps, sanctuaries; others cattle-pens; the majority, fortified steadings. Most likely many were erected as defences against wolves. They are often in positions strategically worthless, and show a singular carelessness with regard to facility of water-supply if they were expected to stand a siege.

CHRISTIAN REMAINS

We may safely date the beginning of Christianity as a power in Ireland to somewhere about A.D. 350–400. There probably were individual Christians even before this date, but they cannot have made much impression on the life of the community. But after about three centuries we begin to find definite traces of a specific Christian art. The earliest church buildings, and for a long time the most important ones, were built of wood, not of stone; and these have all disappeared through fire and decay. Stone building was in a rudimentary stage of development throughout the country; the extensive forests supplied the most obvious and the most easily worked building material. Probably also carved wooden plates did duty for sepulchral memorials: wooden tomb "stones" are still to be seen in some of the country graveyards. Early remains very likely lie hidden in some of the monastic sites; but these are effectually sealed from the excavator by modern interments. The Viking raids of the 9th and 10th centuries must be responsible for the disappearance of many of the earliest works of art.

The only remains of wooden constructions that we possess are the fragments of framed houses found in some of the lake-dwellings (commonly called in the country *crannogs*)—artificial islands made by piling earth and stones on the bottoms of the shallower lakes, and after securing them with a revetment of stones or wattlework, erecting a dwelling-house in the middle. These structures began in the La Tène period, were much in use (to judge by the remains found within them) about the 7th century, and were not wholly abandoned until about the end of the 16th century. The fragmentary structures which they bear are insufficient for us to gauge fairly the skill of the ancient builders in wood. Certain features of the earliest stone churches are evidently translations, so to speak, of constructional details proper to wood into stone, where they are merely otiose. The arch is not used for the larger openings in the earliest structures, though its use for small windows shows that its principle was understood from the first. The stones are set without mortar, or at most in mud. There is much variety in the character of the masonry, but this depends on the skill of the local masons and on the materials at their disposal, and is of no chronological significance. After the Irish missions to the Continent began, the stone building in the country began to improve notably. The Romanesque style was introduced and successfully practised: some very remarkable buildings were produced especially in the 12th century, such as King Cormac's chapel at Cashel, the Nunnery church at Clonmacnois, and the cathedral of Clonfert.

The round towers possess neither the historical nor the architectural importance which controversialists once attributed to them. They are simply the detached campaniles of the churches with which they are invariably associated: they were erected during the time of the Scandinavian raids, when watchtowers and keeps were as necessary as belfries to the churches which had treasures to guard.

The *scriptorium* was one of the busiest centres of industry in an ancient monastery. A sufficient number of manuscripts survive to prove the nature of the work there carried on. The oldest manuscript completely in the Irish language, the *Book of the Dun Cow* (so called from the animal from whose hide its vellum was said to have been manufactured) was written at Clonmacnois some time before A.D. 1106, but is founded on much earlier exemplars, now lost. These literary manuscripts however concern us less than the illuminated books, of which a considerable number was produced: those that survive date from the 8th century to the 11th. The documents thus enriched are psalters, service-books, and, especially, gospels; the enrichments consist not so much in miniatures as in an artistic treatment of the letters of the text itself; these are worked with great ingenuity into fantastic knots

and monograms, and decorated with applied ornament of great beauty. In the *Gospels of Kells* (probably of the middle of the 9th century) the art attains its high-water mark; some pages of this manuscript, especially the monogram of the name of Christ at the beginning of the Gospel of St. Matthew, rank among the finest illuminations in existence.

The art of these illuminations is one with the art of the metal-worker and the sculptor, differing only in the medium employed. It is a provincial phase of the great decorative art practised by Celtic and Teutonic peoples alike, though with differences of idiom, in the 6th to the 12th centuries. It consists of devices founded on such geometrical devices as spirals and interlacements, and on figures of animals or parts thereof, often conventionalized almost out of recognition. Patterns derived from the vegetable world are found in certain of the Teutonic regions, but are almost completely absent from the Celtic works of art.

Like the art of illumination, that of the metal-worker was almost wholly devoted to the service of the Church—save for ornamental pins and brooches, of which a number of very fine specimens have survived. Of these the best-known is the (falsely so called) *Tara brooch*, a work probably of about A.D. 800. It was found on the sea-shore at Bettystown, south of Drogheda, and is now preserved in the collection of the Royal Irish academy. On the reverse side is elaborate chasing, founded mainly on animal forms; on the face are sunk panels filled with ornament in extremely delicate filigree.

The more specifically ecclesiastical works in metal may be classed under the headings of bells, shrines, chalices and processional crosses. The bells used by the early Irish ecclesiastics were adaptations of cattle-bells, like those in Switzerland and elsewhere. They are rectangular, not round, in horizontal section. The earlier specimens, including the famous bell of St. Patrick, are of iron (sometimes brazed on the surface); the later are cast bronze. Bells are usually without ornament, save occasional decorative treatment of the handle; a few specimens are engraved with simple decoration. One is inscribed, and can be dated A.D. 908.

The shrines are of several different varieties, depending upon the nature of the object to be enshrined. Caskets for bones were made in the form of the ordinary church building of the time (understood to be the form in which the Temple of Solomon had been designed); or else in the shape of the part of the body from which the bone came. The best-known example of the latter type is the shrine of St. Laichtin's forearm, in the Royal Irish academy's collection, a work of the 12th century. Those meant for books were flat square boxes, of the size and shape of the volume which they were intended to contain. The books were not preserved in these shrines for perusal; they were holy relics, and were not meant to be taken out of their receptacle. Had they not been thus preserved, they would have perished: for the book which had belonged to a notable saint was accredited with miraculous powers; strips were cut from it to make amulets, water was poured over it to acquire healing virtues, and, according to Bede, books from Ireland were in especial request in England, for scrapings from their pages were a remedy against snake venom. Shrines for bells and crosiers, again, took the form of the object enclosed within them.

The solitary chalice which has survived from the days of Celtic Christianity far surpasses the best of these objects in artistry. It was found near Ardagh, Co. Limerick, and is now in the Royal Irish academy's collection. It is richly decorated with bands of chased and filigree panels, and its beauty is enhanced by the use of enamel, crystal, mica, glass and amber. It is a worthy companion to the *Gospels of Kells*, with which it is probably contemporary.

The one processional cross that has survived is the so-called Cross of Cong, made at Roscommon in or about 1125 to enshrine a fragment of the true cross. Its late date is reflected in the character of its ornament; the pure interlacements and other geometrical decoration of the Ardagh chalice give place to patterns founded on contorted animal figures. The cross-head, which alone remains, is about 2ft. high. It rises from the jaws of a monstrous

animal head. The surface is covered with bronze plates, enriched with silver and enamel, and with applied panels of open work or what we may call false filigree representing animal figures in fantastic knots. In the centre of the face is a large crystal, behind which we may presume that the relic, or what is left of it, is still lying. On the sides are inscriptions in Latin and in Irish, explaining the purpose of the cross, and asking for prayers for all those concerned in its manufacture. The back had an inlaid saltire, presumably of gold, which some sacrilegious thief has picked out.

Numerous remains of sculptured art in stone exist in Ireland, beginning about the middle of the 8th century. They take the form of sepulchral slabs, carved crosses, or the sculptured decoration of church buildings. At Clonmacnois there is a valuable series of slabs, commemorating inmates of the monastery. These sometimes bear the names of persons known from other sources, and are therefore datable: it has been found possible to determine a sequence of styles from these, extending over four centuries. Of much greater importance are the standing crosses, erected in various important ecclesiastical centres. These are in some cases memorials of individuals, such as the fine cross erected at Clonmacnois by Abbot Colman in memory of his friend and patron, Flann, king of Ireland, who died in A.D. 914. Others seem to mark the limits of the monastic enclosure. Others are dedicatory, erected, perhaps, in fulfilment of a vow; such is the "Cross of Patrick and Columba" at Kells, Co. Meath. The earliest standing crosses are perfectly simple, being merely stones carved into a cross form. But about the beginning of the 10th century a much greater elaboration began. The so-called Celtic cross had by now been evolved—a Latin cross with a circular wheel surrounding the centre, probably an attempt to suggest a halo of glory. The surface of the shaft and head of the cross is usually divided into panels, each containing either ornamental devices or else figure subjects. The great majority of the latter which have been identified represent biblical scenes, chosen for their homiletic value—the Fall of Man, the Sacrifice of Isaac, and so forth. A few scenes which cannot be identified may possibly represent local events familiar at the time of the erection of the monument, but now forgotten.

The Scandinavians.—Two important foreign influences have profoundly affected the life of Ireland. The first was that of the Scandinavians, who began their piratical raids in the latter part of the 8th century. For over 200 years they continued their depredations, and did incalculable damage to the material welfare and to the *morale* of the country. But on the other hand they imported their own peculiar variety of the north European art, and from this and the native style there sprang a hybrid which produced works of great beauty: the cross of Cong is one of these. Nevertheless, despite the hold which the Scandinavians had upon the country, comparatively few objects of definitely Scandinavian type have been found there. Only one Scandinavian cemetery has been discovered, and the number of Runic inscriptions is far less than analogy with other Scandinavianized countries would lead us to expect.

The Anglo-Normans.—In 1172 came the Anglo-Norman invasion, which completely overturned the traditional life of the country. From that date onwards foreign methods and ideas impressed themselves with increasing intensity. The *immediate* result of the invasion was the total extinction of the traditional arts. Typical of the resultant chaos is that strange product, Irish Gothic architecture. There is nothing like it anywhere else. It is a curious jumble of styles and periods; and the mouldings which in English Gothic afford an infallible guide to chronology in ambiguous cases, are either totally absent, or else share in the general eccentricity. The Romanesque style had been voluntarily adopted, and had a healthy natural growth in the country: the Gothic style was violently forced on the country from without, and was never assimilated.

More prominent and characteristic remains of mediaeval Ireland are the numberless castles. At first wooden towers (*breteche*) erected on earth mounds (*motte*), these developed along lines parallel to those followed by castles in England. They are thus

hardly monuments of Irish archaeology pure and simple, but of the archaeology of an extension of England. Naturally none of the temporary wooden towers survive, though the place-name *Brittas*, which is not infrequent, preserves a reminiscence of them, "*Brittas*" being a corruption of *bretesche*; and there are numerous *mottes* still in existence, such as the splendid example at Castle-town Geoghegan, Co. Westmeath. The castles of Ireland are of all sizes and dates, from the great structure at Trim, founded in 1173, down to the humble "peel-towers"—small square structures of two or three storeys—some not earlier than the 17th century. The history of Ireland after the Norman invasion is a history of decay and degeneration, and it is vividly reflected in all the remains of antiquity that have come down out of those troubled centuries.

IRELAND, CHURCH OF. The beginnings of Christianity in Ireland are difficult to trace, but there is no doubt that the first Christian missionary whose labours were crowned with any considerable success was Patrick (fl. c. 450), who has always been reckoned the patron saint of the country. For six centuries the Church of which he was the founder occupied a remarkable position in Western Christendom. Ireland, in virtue at once of its geographical situation and of the spirit of its people, was less affected than other countries by the movements of European thought; and thus its development, social and religious, was largely independent of foreign influences, whether Roman or English. In full communion with the Latin Church, the Irish long preserved many peculiarities, such as their monastic system and the date at which Easter was kept, which distinguished them in discipline, though not conspicuously in doctrine, from the Christians of countries more immediately under papal control

(see *IRELAND: Early History*). The incessant incursions of the Danes, who were the scourge of the land for a period of nearly three hundred years, prevented the Church from redeeming the promise of her infancy; and at the date of the English conquest of Ireland (1172) she had lost much of her ancient zeal and of her independence. By this time she had come more into line with the rest of Europe, and the Synod of Cashel put the seal to a new policy by its acknowledgment of the papal jurisdiction and by its decrees assimilating the Church, in ritual and usages, to that of England. There was no thought of a breach of continuity, but the distinctive features of Celtic Christianity gradually disappeared from this time onwards.

The Church of Ireland, as at present constituted, is the outcome of the extension to Ireland of the principles of the English Reformation. English influence was strong only in the region round Dublin (known as the Pale); and beyond this district the Irish were not disposed to view with favour any ecclesiastical reforms which had their origin in England. Thus from the days of Henry VIII. the Reformation movement in Ireland was hindered by national prejudice, and it never succeeded in gaining the allegiance of the Irish people as a whole. The policy which directed its progress was blundering and stupid, and reflects little credit on the English statesmen who were responsible for it. No attempt was made to commend the principles of the Reformation to the native Irish by conciliating national sentiment; and the policy which forbade the translation of the Prayer Book into the Irish language, and suggested that where English was not understood Latin might be used as an alternative, was doomed to failure from the beginning. And, in fact, the reformed church of Ireland is to this day the church of a small section only of the population.

REFORMATION AND AFTER

The Reformation period begins with the passing of the Irish Supremacy Act 1537. In Ireland the mass of the people were less deeply affected by the religious controversies of the times than in Great Britain. At Mary's accession five bishops either abandoned, or were deprived of, their sees; but the Anglo-Irish who remained faithful to the Reformation were not subjected to persecution such as would have been their fate on the other side of the Channel. Again, under Elizabeth, while two bishops were deprived for open resistance to the new order of things, and while stern measures were taken to suppress treasonable plotting against the constitution, the uniform policy of the government in ecclesiastical matters was one of toleration. James I. caused the Supremacy Act to be rigorously enforced, but on political rather than on religious grounds. The episcopal succession, then, was unbroken at the Reformation. The question of the continuity of the pre-Reformation Church with the Church of the Celtic period before the Anglo-Norman conquest of Ireland is more difficult. The present Church of Ireland claims to be the direct and legitimate successor of the Church of the 14th and 15th centuries, but it cannot be demonstrated that any existing organization is continuous with the Church of St. Patrick.

On the accession of Charles II. the Church was strengthened by the translation of John Bramhall (the most learned and zealous of the prelates) from Derry to the primatial see of Armagh, and the consecration of twelve other bishops, among whom was Jeremy Taylor. But though the Church had now been reformed for more than 100 years, she had made little progress; and the tyrannical provisions of the Penal Code introduced by the English government made her more unpopular than ever. The clergy, finding their ministrations unacceptable to the great mass of the population, were tempted to indolence and non-residence; and although bright exceptions could be named, there was much that called for reform. To William King (1650–1729) bishop of Derry, and subsequently archbishop of Dublin, it was mainly due that the work of the Church was reorganized, and the impulse which he gave it was felt all through the 18th century. In 1800 the Act of Union was passed by the Legislature; and thenceforward, until Disestablishment, there was but one "United Church of England and Ireland."

The dissatisfaction felt by the majority of Irishmen, because of

the continued existence of the Established Church in her privileged position, became increasingly plain as the years passed. Her position had been pledged to her by the Act of Union, and she was undoubtedly the historical representative of the ancient Church of the land; but such arguments proved unavailing in view of the visible fact that she had not gained the affections of the people. The census of 1861 showed that out of a total population of 5,798,967 only 693,357 belonged to the Established Church, 4,505,265 being Roman Catholics; and once this had been made clear, the passing of the Act of Disestablishment was only a question of time. Introduced by W. E. Gladstone, and passed in 1869, it became law on the 1st of January, 1871.

The Church was thus suddenly thrown on her own resources, and called on to reorganize her ecclesiastical system, as well as to make provision for the maintenance of her future clergy. A convention of the bishops, clergy and laity was summoned in 1870, and its first act was to declare the adherence of the Church of Ireland to the ancient standards, and her determination to uphold the doctrine and discipline of the Catholic and Apostolic Church, while reaffirming her witness, as Protestant and Reformed, against the traditions of Rome. Under the constitution then agreed on, the supreme governing body of the Church is the General Synod, consisting of the bishops and of 208 clerical and 416 lay representatives of the several dioceses, whose local affairs are managed by subordinate Diocesan Synods. The bishops are elected as vacancies arise, and, with certain restrictions, by the Diocesan Synods, the Primate, whose see is Armagh, being chosen by the bishops out of their own number. The patronage of benefices is vested in boards of nomination.

The finances are controlled by the Representative Church Body, to which a sum sufficient to provide life annuities for the existing clergy (2,043 in number) was handed over by the Church Temporalities Commissioners in 1870, together with £500,000 in compensation for private endowments. So skilfully was this fund administered, and so generous were the contributions of clergy and laity, at and since Disestablishment, that while on Dec. 31, 1926 only 17 annuitants were living, the total assets in the custody of the Representative Church Body amounted at that date to £10,240,750. Since 1869 the members of the Church have paid in to the Representative Body a total sum of £895,000. At the census of 1911 the number of members of the Church of Ireland was 547,490, or 13.1% of the entire population.

IRELAND, NATIONAL UNIVERSITY OF. The National University of Ireland had its beginning in the Queen's university—incorporated in 1850. In 1880 the Queen's university was superseded by the Royal University of Ireland. It in turn was dissolved on Oct. 31, 1907, giving place to the National university. Of the three Queen's colleges, founded in 1845 at Belfast, Cork and Galway, which had formed the constituent colleges, of its two predecessors, Belfast became a separate university, Cork and Galway were taken over as constituent colleges, while a new college was projected in Dublin and Maynooth added as a recognized college.

The university has temporary accommodation at 48 and 49 Merion square, Dublin.

The Senate consists of 35 members, one of whom, it is laid down in the charter, must be a woman. Certain of the members are elected by Convocation, others are nominated and four are co-opted.

The university has three representatives in Dail Eireann and there were, on the register of 1925-26, 2,461 persons qualified to vote for the members of the Dail. The president of each university college becomes in rotation a vice-president of the National university. There are eight faculties, in arts, philosophy

and sociology, Celtic, science, law, medicine, engineering and architecture and commerce. Music is included in art and Celtic study. There is no special professorate as such, but classes in all faculties are in operation at all the constituent colleges. The library of the university contains the Zimmer collection of Celtic books. There are also various scholarships and prizes of assistance to students. (See also **UNIVERSITIES**.)

See *The Year Book of the Universities of the Empire* (1929); *Minerva-Index Generalis*.

IRELAND, NORTHERN, a part of the United Kingdom of Great Britain and Northern Ireland, with a certain measure of local self-government. The capital city is Belfast on the river Lagan, which is an important centre of the shipbuilding, linen, tobacco, ropemaking, and distilling industries. A considerable trade in live-stock and agricultural produce is also carried on from this port. The following table shows the populations (census 1926) and areas of the counties and county boroughs composing Northern Ireland:—

County or County Borough.	Area in statute acres.	Persons.	Males.	Females.
Antrim	751,886	191,643	92,506	99,047
Armagh	327,902	110,070	53,009	56,461
Belfast Co. Borough	16,520	415,151	195,539	219,612
Down	609,239	209,238	101,202	108,026
Fermanagh	457,376	57,984	30,102	27,882
Londonderry (excluding Co. Borough)	520,750	94,534	47,119	47,415
Londonderry Co. Borough	2,579	45,159	20,785	24,374
Tyrone	806,919	132,792	67,136	65,656
Total	3,493,171	1,256,561	608,088	648,473

See also the articles on the separate counties and boroughs.

HISTORY

Under the Government of Ireland Act, 1920, the Lord Lieutenant summons, prorogues and dissolves parliament. He gives or withholds the Royal assent to bills passed by the Senate and House of Commons, subject to the following limitations:—

“(1) He shall comply with any instructions given by His Majesty in respect of any such bill or order; and

“(2) He shall, if so directed by His Majesty, reserve any such bill or order for the signification of His Majesty's pleasure, and a bill or order so reserved shall not have any force unless and until within one year from the day on which it was presented to the Lord Lieutenant for His Majesty's assent, the Lord Lieutenant makes known that it has received His Majesty's assent.”

Northern Ireland is represented in the Parliament of the United Kingdom by 13 members. For the purposes of local self-government it has a parliament consisting of two houses (1) the Senate, composed of the lord mayor of Belfast, the mayor of Londonderry and 24 senators elected by the members of the House of Commons, and (2) the House of Commons, composed of 52 members who are elected by the same electors and in the same manner as the members returned by constituencies in Northern Ireland to the parliament of the United Kingdom, though until 1929 at general elections they were elected on the principle of proportional representation, each elector having one transferable vote. Money bills can only originate in the House of Commons and may not be amended by the Senate. If the Senate reject, or fail to pass, or pass with amendments to which the House of Commons will not agree, a public bill which is sent up to the Senate at least one month before the end of the session, and if the House of Commons in the next session again pass the bill, with or without any amendments which have been made or agreed to by the Senate, and the Senate reject or fail to pass it, or pass it with amendments to which the House of Commons will not agree, provision is made for the holding of a joint session. The parliament has power generally to make laws for the peace, order and good government of Northern Ireland for matters exclusively relating to the province. The Crown, armed forces, defence of the realm, relations with foreign States, etc., are excluded

from its power; nor can it make laws interfering with religious equality, taking property without compensation, etc., within its own area. All executive power in Northern Ireland continues vested in the King, but is exercised by the Lord Lieutenant or other chief executive officers for the time being appointed in his place. Certain taxes, such as customs and excise duties, are reserved to the imperial parliament; the postal service, post office savings bank, etc., were reserved temporarily, pending the formation of the proposed Irish union. The Act abolishes the Supreme Court of Judicature for Ireland, and establishes the Supreme Court of Judicature of Northern Ireland, consisting of two divisions, the High Court and the Court of Appeal.

Developments After 1920.—The Lord Lieutenant of Ireland (Viscount FitzAlan of Derwent) on May 4, 1921 summoned a parliament of Northern Ireland to meet in Belfast on June 7 following. The election of members of the House of Commons was held on May 24, the Unionists securing 40 seats to six Nationalist and six Sinn Fein. Elections for the Senate were held on June 12, and 24 Unionists were returned unopposed. The Ulster Unionist Council had on Feb. 4 unanimously elected Sir James Craig (Lord Craigavon) as leader of the party. The Nationalist and Sinn Fein members did not attend the opening of parliament. The Hon. Hugh O'Neill was elected as Speaker of the House of Commons and the Marquess of Dufferin and Ava as Speaker of the Senate. On June 22 parliament was formally opened by King George V. The first cabinet was constituted as follows: Prime Minister (Sir James Craig), Minister of Finance (Mr. H. M. Pollock), Minister of Home Affairs (Sir R. D. Bates), Minister of Labour (Mr. J. M. Andrews), Minister of Education (The Marquess of Londonderry), Minister of Agriculture and Commerce (Mr. E. M. Archdale). The Ministry of Commerce was subsequently (1925) separated from the Ministry of Agriculture under a minister with cabinet rank (Mr. J. M. Barbour).

Sir James Craig immediately made it clear that his policy was to preserve the existence of Northern Ireland as an integral part of the United Kingdom, and, while willing to contemplate common action with Southern Ireland under the Government of Ireland Act, to resist union with the rest of Ireland in any system which would involve separation from Great Britain and the abandonment of the representation of Northern Ireland in the Imperial Parliament. The first task of the Government was to restore internal order. Political and religious animosities, to which unemployment arising from the decline in trade and industry had added fuel, had been kindled to a dangerous heat. Outbreaks of civil disorder leading to murder and arson had taken place. The anti-British party in Southern Ireland had undoubtedly contributed to increase the difficulties of the Government, presumably in the hope of forcing an all-Ireland form of government by making government under the Act of 1920 impossible. However, the disruption of this political party, which followed upon the Irish agreement of the winter of 1921-22, accompanied by an outbreak of civil war in Southern Ireland, actually eased the situation in Northern Ireland, as it caused the withdrawal of certain elements of disorder which, organized and introduced from outside, were now called off to take part in the quarrels of their leaders.

INTERNAL STABILIZATION

After the setting up of the Provisional Government in Southern Ireland, the Royal Irish Constabulary was disbanded under the Constabulary (Ireland) Act, 1922, which received the Royal Assent on Aug. 4, 1922 and modified the provisions of the Government of Ireland Act by providing for the disbandment of the constabulary, in lieu of the transfer to the Government of Northern Ireland of the members of the forces serving in that area. Before this disbandment was completed the Parliament of Northern Ireland had established a new police force, the Royal Ulster Constabulary, and a considerable proportion of disbanded members of the Royal Irish Constabulary received appointments in the new force. A large body of auxiliary police was also organized and, thanks to vigorous measures both in and out of Parliament, order was restored in a comparatively short time.

The Irish Free State (Agreement) Act, 1922, affected Northern

Ireland (although she was not a party to the agreement thereby given legislative sanction) in the following ways. It purported to give Dominion status to Ireland as a whole. It put a stay upon the exercise of the powers of the parliament and Government of the Irish Free State, as respects Northern Ireland, until the expiration of one month. It enabled Northern Ireland to vote herself out of the Free State by means of an Address presented to His Majesty by both houses of parliament of Northern Ireland, before the expiration of the month above referred to, and it attached to the presentation of such an Address the consequence that a commission was to be set up consisting of three members, one to be appointed by the Government of the Irish Free State, one to be appointed by the Government of Northern Ireland, and one (who was to be the chairman) to be appointed by the British Government, in order to "determine in accordance with the wishes of the inhabitants, so far as may be compatible with economic and geographic conditions, the boundaries between Northern Ireland and the rest of Ireland. It expressly preserved the Council of Ireland and the Irish Free State representation thereon, whilst depriving the Council of any powers in that State; and it offered to Northern Ireland, as an alternative to going out of the Free State, a continued existence under the Government of Ireland Act, subject to an over-riding jurisdiction of the parliament and government of the Irish Free State, in all matters in respect of which legislative power is withheld from the Parliament of Northern Ireland under that Act.

The majority of the points in which the constitution of Northern Ireland was affected by the setting up of the Irish Free State received attention from the Imperial legislature in the Irish Free State (Consequential Provisions) Act, 1922, which came into force on the same day as the Act providing for the Free State Constitution. This Act contained various provisions which were to take effect in the event of Northern Ireland voting herself out of the Irish Free State under Article 12 of the original agreement. This voting out was immediately accomplished, and thus authority was given for various constitutional changes. Subject to the provisions of the first schedule (Modification of the Government of Ireland Act, 1920, etc.) to the Act, the Government of Ireland Act was only to apply to Northern Ireland. This schedule provided for the appointment of a Governor of Northern Ireland, and for the application to him of the provisions of the Government of Ireland Act, 1920, with respect to the Lord Lieutenant. A Privy Council of Northern Ireland was established and a Great Seal of Northern Ireland authorised. On Dec. 9, 1922 the Duke of Abercorn was appointed Governor of Northern Ireland.

The most important legislative achievement of the Government of Northern Ireland has been the Education Act of 1923. Based largely on the recommendation of a committee of enquiry appointed in 1921 under the chairmanship of Sir R. Lynn, M.P., the Act established the principle of popular control under the county borough and county councils as local education authorities, the latter having power to appoint administrative sub-areas under "regional committees." The Intoxicating Liquor Act of the same session was an important piece of temperance legislation and achieved considerable reform in the sale of intoxicating liquors.

Boundary Question.—The chief obstacle to the development of better relations with the Irish Free State during the years 1923 and 1924 was the boundary question. The Government of Northern Ireland declined to appoint a Commissioner under Article 12 of the Irish Free State (Agreement) Act, 1922, and, as a consequence, the Irish Free State (Confirmation of Agreement) Act, 1924, was passed by the Imperial Government whereby, in the event of the continued refusal of the Government of Northern Ireland to appoint a boundary commissioner, the power of appointment residing in that Government was transferred to the British Government. The British Government and the Government of the Irish Free State had appointed as their respective Commissioners, Mr. Richard Feetham, a judge of the High Court of the Union of South Africa, and Prof. J. McNeill. Upon the passing of the above Act, the British Government appointed Mr. J. R. Fisher, barrister-at-law, as the Commissioner for Northern Ireland.

The boundary commission occupied upwards of a year in visiting, and hearing evidence in the various border districts in Ireland, and in considering the information so obtained. In Nov. 1925, on the eve of the promulgation of the report of the commission, the Free State commissioner withdrew. A conference was then held in London between the three governments represented on the commission, and a further agreement was concluded on Dec. 3, 1925. By the agreement, the Ireland (Confirmation of Agreement) Act, 1925, the three Governments "being united in amity" and "being resolved mutually to aid one another in a spirit of neighbourly comradeship" achieved the settlement which is set out in Article 1:—

The powers conferred by the proviso to Article 12 of the said Articles of Agreement on the commission therein mentioned are hereby revoked, and the extent of Northern Ireland for the purposes of the Government of Ireland Act, 1920, and of the said Articles of Agreement, shall be such as was fixed by sub-section (2) of section one of that Act.

The Act also provided for the transfer from April 1, 1926, of the Council of Ireland powers in relation to Northern Ireland to the Government of Northern Ireland. The constitution of Northern Ireland could now be described as being settled with finality.

The second parliament of Northern Ireland was elected in 1925, when Sir James Craig was again returned to power with a substantial majority over all other parties. All the Nationalist members of the Opposition had taken their seats before the close of the 1927-28 session. Only two members belonging to the Sinn Féin party still remained outside the House. The acceptance of the Parliament by the Nationalist party marks the abandonment of the original policy of opposition by abstention and the commencement of a new policy of opposition by recognized constitutional means. The establishment of a separate legislature has not led to a further differentiation of the law in Northern Ireland from that in other parts of the United Kingdom, but rather to the assimilation of the law in Northern Ireland to the law in Great Britain, and to the enlargement of the status of the subject in Northern Ireland to that of the subject in Great Britain. It is, perhaps, to this undertaking above all that the parliament of Northern Ireland, on a study of its statute-book, will be found to have addressed itself from its earliest inception. Particularly has social legislation in Northern Ireland kept pace with that at Westminster, adopting its various measures for unemployment insurance, and its comprehensive measure of 1925 for contributory old age pensions and pensions for widows and orphans of insured workers.

Moreover, it is to be noted that constitutional changes, either already made, such as the extension of the franchise to women on equal terms with men, or declared by the Government to be imminent, such as the abandonment of proportional representation and a reversion to single-member constituencies, bring electoral practice in Northern Ireland once more into line with that in Great Britain. (L.)

Defence.—From the military point of view, Northern Ireland forms one of the district commands of the British army. The commander is a Major-General, with his headquarters at Belfast. The troops under his command include 4 battalions of infantry, a signal company and the usual departmental troops. There are also recruit depots for battalions of the British army which are recruited in Northern Ireland, one at Omagh, for 2 battalions, and one at Armagh, for one battalion. There is also a British coast defence garrison at Lough Swilly, including a heavy battery of artillery, a fortress detachment of engineers, some signals, etc. There are no territorial or local troops in Northern Ireland. The strategic importance to the United Kingdom of all the harbours of Ireland is obvious to all students of the general problem of military defence. On this subject the late Admiral Mahan expressed his opinion that Ireland stands across "and controls" the approaches to the United Kingdom from the westward.

(G. G. A.)

FINANCIAL AND ECONOMIC HISTORY

Finance.—The financial provisions of the Government of Ireland Act, 1920, were necessarily of an intricate and comprehensive

character, as not only did that Act completely overthrow the whole system of finance in force since the Act of Union of 1800, but went further and set up in Ireland two Exchequers, each under an entirely separate jurisdiction. Subsequent events have considerably modified the operation of the 1920 Act and it is therefore not necessary to deal in this article with Northern Ireland's position as regards the Irish Free State but simply to consider the relationship which exists under the Act between Northern Ireland and Great Britain, and the financial system which has been built up in Ulster since 1921.

The newly constituted State was not granted absolute financial autonomy. The Act of 1920 contemplated two distinct classes of revenue, and two classes of expenditure, (1) purely local revenue and expenditure and (2) taxation and expenditure which by reason of the wider issues involved, should not be delegated to a subsidiary authority. Under the first heading fall such duties as stamp duties, death duties and licence duties, together with expenditure on services such as old age pensions, police, education, etc., while included in the second category are the more important duties of income tax and customs and excise, and expenditure on the higher administration of justice, the Land Commission and certain other services.

Revenue.—Approximately 90% of the taxes are imposed and collected by the Imperial Government. In the year 1922-3 the revenue yielded by taxes under the control of the Imperial Government was £10,700,000, while the ordinary "transferred" tax revenue amounted to £923,000. This revenue, after deducting from it the cost of the various services reserved to the Imperial Govt., together with Ulster's contribution towards Imperial expenditure, is remitted to the Exchequer of Northern Ireland, and is used in the ordinary way to meet expenditure on local services. As a further source of revenue to meet the "additional expense incidental to the severance of the two Irish Governments," it was provided that produce of Land Purchase Annuities payable by those agricultural tenants who had bought out their holdings under the Land Purchase Acts (and who had effected their purchases by the payment of annuities extending over a period of 65 years) should be transferred to the Northern Government. After making provisions for a sinking fund with the object of ensuring a permanent revenue from this service, these land annuities produce a net revenue of £550,000 which should be added to the figures given above.

Fiscal Uniformity.—The control by the Imperial authority of the main sources of revenue requires almost complete fiscal uniformity between Ulster and Great Britain, and necessarily ensures that the industrial and general economic policy of the Province must, in practice, largely conform to that of the Imperial Government, not only in a local sense, but also in its commercial relations with foreign countries. Hence no tariff barriers can be erected between Northern Ireland and Great Britain, and the normal flow of merchandise between the two areas has continued without the inconveniences and hindrances resulting from the imposition of customs duties.

Contribution to Imperial Expenditure.—The Act of 1920 enacted that the Province should make a fixed statutory contribution to "Imperial" services, but this proving unworkable, it was eventually agreed to set up an arbitration committee which, after sitting for two years and having heard expert evidence on both sides, issued its final award in March 1925, settling the principles upon which Ulster's contribution is in future to be assessed. In brief, the contribution will be the balance of revenue over expenditure; for the purpose of making this calculation the taxes over which Ulster has control are to be presumed to raise a sum proportionate to the yield of similar taxes in Britain; while on the expenditure side the Province is allowed for development and social service a sum proportionate to the amounts required by Britain for similar purposes.

Reduction in Revenue.—The reductions in taxation made by the Chancellor of the Imperial Exchequer from time to time in the intervening years between 1922 and 1925 have had their reaction on the revenues of Northern Ireland resulting in an annual diminution in revenue of approximately £1,389,000. The severe

depression in trade has also been responsible for a further diminution in revenue; actual yield of taxes levied in Northern Ireland by the Imperial Government falling from £10,562,000 in 1922 to £8,217,000 in 1925. These reductions were naturally reflected in a corresponding decrease in the contribution which Northern Ireland was able to make towards the cost of Imperial services.

Public Debt.—Unhappily the establishment of the Government of Northern Ireland synchronised with the beginning of a period of profound commercial and industrial depression, with its natural reaction on employment. The principal industries of the Province—shipbuilding and the linen trade—suffered to an unwanted degree, thus compelling the newly-formed Government to finance the Unemployment Insurance Fund to an extent quite disproportionate to that of Great Britain, whose varied industries scattered over a wide area ensure a greater degree of solvency for its insurance scheme. At the end of the financial year—1924-5—the accumulated deficit of the unemployment fund was approximately £2,300,000. (The figures given throughout this article are the latest available: administrative difficulty having considerably delayed the publication of others.)

Capital Funds.—On its establishment the Government of Northern Ireland had received its apportioned share of the different capital funds previously set up in Ireland for administrative purposes, and including amongst others the Church Temporalities Fund, Teachers' Pension Fund, Development Fund, etc. It had in addition created certain other capital and sinking funds. To a very considerable extent the requirements of the Unemployment Insurance Fund and of Local Authorities and others to whom loans were made have been met by the temporary utilisation of this available capital. These sources were, however, insufficient to meet all the demands made on the Government, and a public debt was therefore created by the issue of Ulster Savings Certificates in April 1922, followed in Nov. 1925 by an Ulster Loan Stock issue of £2,000,000. The former, guaranteed by the British Government and providing a remunerative investment for savings, met with an immediate and sustained response throughout the Province. By March 31, 1925 a sum of £1,500,000 (after deducting repayments) had been invested in this way. The proceeds of the Ulster Loan Stock issue are available only for the purposes mentioned in the Government Loans and Exchequer Provisions Act (N.I.) 1925, which do not include the making of advances to the Unemployment Fund. Of the stock £1,000,000 was reserved for the investment of Government funds, the remaining moiety being taken up by public subscription.

The Budget.—Statistics regarding the public finances of Northern Ireland for the year ended March 31, 1925 showed a total revenue, including Post Office receipts, of approximately £11,336,000; the total expenditure for the same period amounted to £7,713,000, leaving a balance of revenue over expenditure of £3,623,000. Of this £3,472,000 was contributed to Great Britain, leaving a net surplus of £151,000.

Production and Industry.—Agriculture is one of the principal industries of the country and large quantities of butter, eggs and general agricultural produce are exported to Great Britain. Considerable quantities of flax are also grown and it is expected that the research work now being undertaken in this branch of agriculture will not only improve the quality of the flax but will also greatly stimulate general interest in this product.

During the post-War period the trade in live stock greatly increased. Up to 1926 Ulster had escaped the ravages of foot-and-mouth disease, and indeed was particularly free from outbreaks of animal diseases generally. During 1924 a total of 424,000 cattle, etc., were exported, chiefly to Great Britain.

The main industries of Northern Ireland are the manufacture of linen, shipbuilding, engineering, rope making and distilling. The linen industry normally employs directly or indirectly approximately 120,000 workers. Over 1,000,000 flax spindles are in use, representing one-third of the world's entire flax-spinning capacity; 40,000 looms are engaged in weaving. The major portion of the shipbuilding industry is located at Belfast, where a large number of the world's most famous vessels have been built, including the well-known "Titanic" and "Olympic." During 1923,

12 mercantile steam vessels with a total tonnage of 75,782 were launched in the North Irish yards.

Over 50 important firms are engaged in Belfast and the immediate vicinity in the manufacture of textile machinery of all kinds; heating, ventilating and drying plants and almost every variety of equipment for factories. There are some 12 modern distilleries operating in Ulster which together produced during the year ended March 31, 1924 a total of 2,534,426 proof gallons of spirits. A number of other industries are carried on. Belfast possesses the largest ropeworks in the world, which employ over 3,500 persons and can produce 350 tons per week of all classes of ropes and twines. Tobacco, soap, woollen goods, felt and aerated waters are also manufactured.

Trade.—Northern Ireland carries on a very considerable export trade. Statistics for 1923 show that the value of the exports for that year to Great Britain and foreign countries totalled £66,000,000, while the imports for the corresponding period amounted to £65,000,000.

Finance.—There are three banking companies having their head offices in Northern Ireland, viz.: the Belfast, Ulster and Northern banks. In addition there are several other banks operating in Ulster. The purely North Irish banks have all a close working agreement with one of the leading English Joint Stock Banks. The deposits in these three banks amounted in 1924 to over £48,000,000 while the advances of various descriptions totalled £31,000,000. In addition to these deposits the sums deposited in Trustee and Post Office Savings banks amounted to almost £9,000,000 in 1924. On Dec. 31, 1924, there were approximately 1,350 living companies registered in Northern Ireland with a nominal capital of £71,000,000 and a subscribed capital of £59,000,000.

An analysis of the registered capital produces the following results:—

Banking, etc.	£11,000,000
Brewing and distilling	2,250,000
Shipbuilding	13,500,000
Textile manufacturers	21,000,000
Engineering	10,000,000
Others	13,250,000
	£71,000,000

Communications.—The principal ports of Ulster are Belfast, Londonderry, Coleraine and Newry, while in addition there are Royal Harbours at Donaghadee and Ardglass. Of these Belfast is the most important. Belfast Harbour covers 2,287 acres and possesses a total lineal quayside of 26,512 feet. There are in addition, five graving docks, the largest of which is 850ft. long and 96ft. wide at the entrance. During 1923 the number of vessels arriving at ports in Northern Ireland totalled 12,383 with an aggregate tonnage of 4,872,225.

Northern Ireland is exceptionally well provided with roads and a very marked increase in the use of motor transport has been noticeable in the post-War period. There were altogether 12,892m. of roads in 1925 consisting of:—

Main trunk roads and the more important inter-town routes	miles 1,023
Less important inter-town routes	1,111
All other roads	10,758
	12,892

There are seven private railway undertakings situated wholly in Northern Ireland and five others extending into the Irish Free State. The total mileage in Northern Ireland in 1925 was as follows: standard gauge 815m., narrow gauge 301 miles. The authorised capital of the railways wholly in Ulster is £1,888,757 and of those partly in Ulster and partly in the Free State £11,141,356. The total receipts in 1923 amounted to £1,090,526 in the case of Ulster railways and £2,395,285 in respect of the others.

IRENÆUS (b. c. 130), bishop of Lyons at the end of the 2nd century, was one of the most distinguished theologians of the ante-Nicene Church. Very little is known of his early history. His childhood was spent in Asia Minor, probably at or near Smyrna; for he says (*Adv. haer.* iii. 3, 4, and *Euseb. Hist. Eccl.* v. 20) that as a child he heard the preaching of Polycarp, the aged bishop of Smyrna (d. 156). He can hardly have been born very long after 130, for later on he frequently mentions having met certain Christian presbyters who had actually seen John, the disciple of our Lord. At the time of the persecution of the Gallic Church under Marcus Aurelius (177) he was a presbyter of the church at Lyons. In 177 or 178 he went to Rome on a mission from this church, to make representations to Bishop Eleutherius in favour of a more lenient treatment of the Montanists. (See MONTANISM; *Eus.* v. 4. 2.)

On his return to Lyons Irenæus was called upon to replace Bishop Pothinus, who had perished in the persecution (*Eus.* v. 5. 8). As bishop he carried on a great and fruitful work. Though the statement of Gregory of Tours (*Hist. Franc.* i. 29), that within a short time he succeeded in converting all Lyons to Christianity, is probably exaggerated, from him at any rate dates the wide spread of Christianity in Lyons and its neighbourhood. He sought to reconcile the numerous sects which menaced the existence of the church. In the dispute on the question of Easter, he endeavoured to effect a compromise, and in particular to exercise a moderating influence on Victor, the bishop of Rome, and his unyielding attitude towards the dissentient churches of Africa, thus justifying his name of "peace-maker" (Eirenaïos) (*Eus. H.E.* v. 24. 28). The date of his death is unknown. His martyrdom under Septimius Severus is related by Gregory of Tours, but by no earlier writer.

The chief work of Irenæus, written about 180, is his "Refutation and Overthrow of Gnosis, falsely so called" (usually indicated by the name *Against the Heresies*). Of the Greek original of this work only fragments survive; it only exists in full in an old Latin translation. The treatise is divided into five books: of these the first two contain a description and criticism of the tenets of various heretical sects, especially the Valentinians; the other three set forth the true doctrines of Christianity. His work is the first systematic exposition of Catholic belief. The foundation upon which Irenæus bases his system consists in the episcopate, the canon of the Old and New Testaments, and the rule of faith. With their assistance he sets forth and upholds, in opposition to the gnostic dualism, *i.e.*, the severing of the natural and the supernatural, the Catholic monism, *i.e.*, the unity of the life of faith as willed by God. The "grace of truth" (the *charisma*), which the apostles had called down upon their first disciples by prayer and laying-on of hands, and which was to be imparted anew by way of succession (*διαδοχή*, *successio*) to the bishops from generation to generation without a break, makes those who receive it living witnesses of the salvation offered to the faithful by written and spoken tradition. The Scriptures of the Old and New Testaments, rightly expounded by the church alone, give us an insight into God's plan of salvation for mankind, and explain to us the covenant which He made on various occasions (Moses and Christ; or Noah, Abraham, Moses and Christ). Finally, the "rule of faith" (*regula fidei*), received at baptism, contains in itself all the riches of Christian truth.

This exposition by Irenæus of the divine economy and the incarnation was taken as a criterion by later theologians, especially in the Greek Church. (*Cf.* Athanasius, Gregory of Nyssa, Cyril of Alexandria, John of Damascus.) He himself was especially influenced by St. John and St. Paul. Before him the Fourth Gospel did not seem to exist for the Church; Irenæus made it a living force. His conception of the Logos is not that of the philosophers and apologists: he looks upon the Logos not as the "reason" of God, but as the "voice" with which the Father speaks in the revelation to mankind, as did the writer of the Fourth Gospel. And the Pauline epistles are adopted almost bodily by Irenæus, according to the ideas contained in them; his expositions often present the appearance of a patchwork of St. Paul's ideas. Certainly, it is only one side of Paul's thought that he displays to us. The great conceptions of justification and atonement are hardly ever touched by Irenæus.

Till recent times whatever other writings and letters of Irenæus are mentioned by Eusebius appeared to be lost, with the exception of a fragment here or there. Two Armenian scholars, Karapet Ter-Mékérttschian and Erwand Ter-Minassian, published from an Armenian translation a German edition (Leipzig, 1907; minor edition 1908) of the work "in proof of the apostolic teaching" mentioned by Eusebius (*H.E.* v. 26). This work, which is in the form of a dialogue with one Marcianus, otherwise unknown to us, contains a statement of the fundamental truths of Christianity. It is the oldest catechism extant, and an excellent example of how Bishop Irenæus was able not only to defend Christianity as a theologian and expound it theoretically, but also to preach it to laymen.

BIBLIOGRAPHY.—The edition of the Benedictine R. Massuet (Paris, 1710 and 1734, reprinted in Migne, *Cursus patrologiae*, Series Graeca, vol. v., Paris, 1857) long continued to be the standard one, till it was superseded by the editions of Adolph Stieren (2 vols., Leipzig, 1848–53) and of W. Wigan Harvey (2 vols., Cambridge, 1857), the latter being the only edition which contains the Syriac fragments. For an English translation see the *Ante-Nicene Library*. Ziegler, *Irenæus, der Bischof von Lyon* (1871); Friedrich Loois, *Irenæus-Handschriften* (Leipzig, 1888); Johannes Werner, *Der Paulinismus des Irenæus* (Leipzig, 1889); Johannes Kunze, *Die Gotteslehre des Irenæus* (Leipzig, 1891); Ernst Klebba, *Die Anthropologie des heiligen Irenæus* (Münster, 1894); Albert Dufourcq, *Saint Irénée* (Paris, 1904); Franz Stoll, *Die Lehre des heil. Irenæus von der Erlösung und Heiligung* (Mainz, 1905); also the histories of dogma, especially Harnack, and Bethune-Baker, *An Introduction to the Early History of Christian Doctrine* (1903); Bonwetsch, *Die Theologie des Irenæus* (1925).

IRENE, the name of several Byzantine empresses.

1. **IRENE** (752–803), the wife of Leo IV., East Roman emperor. Originally a poor but beautiful Athenian orphan, she speedily gained the love and confidence of her feeble husband, and at his death in 780 was left by him sole guardian of the empire and of their ten-year-old son Constantine VI. Seizing the supreme power in the name of the latter, Irene ruled the empire at her own discretion for ten years, displaying great firmness and sagacity in her government. Her most notable act was the restoration of the orthodox image-worship, a policy which she always had secretly favoured, though compelled to abjure it in her husband's lifetime. Having elected Tarasius, one of her partisans, to the patriarchate (784), she summoned two church councils. The first, held in 786 at Constantinople, was frustrated by the opposition of the soldiers. The second, convened at Nicaea in 787, revived the adoration of images and reunited the Eastern church with that of Rome.

As Constantine approached maturity he began to grow restive under her autocratic sway. An attempt to free himself by force was met and crushed by the empress, who demanded that the oath of fidelity should thenceforward be taken in her name alone. The discontent which this occasioned swelled in 790 into open resistance, and the soldiers, headed by the Armenian guard, formally proclaimed Constantine VI. as the sole ruler. A hollow semblance of friendship was maintained between Constantine and Irene, whose title of empress was confirmed in 792; but the rival factions remained, and Irene, by skilful intrigues with the bishops and courtiers, organized a powerful conspiracy on her own behalf. Constantine could only flee for aid to the provinces, but even there he was surrounded by participants in the plot. Seized by his

attendants on the Asiatic shore of the Bosphorus, the emperor was carried back to the palace at Constantinople; and there, by the orders of his mother, his eyes were stabbed out.

Irene reigned in prosperity and splendour for five years. She is said to have endeavoured to negotiate a marriage between herself and Charlemagne; but according to Theophanes, who alone mentions it, the scheme was frustrated by Aëtius, one of her favourites. A projected alliance between Constantine and Charlemagne's daughter, Rothrude, was in turn broken off by Irene. In 802 the patricians, upon whom she had lavished every honour and favour, conspired against her, and placed on the throne Nicephorus, the minister of finance. The haughty and unscrupulous princess, "who never lost sight of political power in the height of her religious zeal," was exiled to Lesbos and forced to support herself by spinning. She died the following year. Her zeal in restoring images and monasteries has given her a place among the saints of the Greek church.

2. IRENE [DUCAS] (c. 1066-c. 1120), the wife of Alexius I. The best-known fact of her life is the unsuccessful intrigue by which she endeavoured to divert the succession from her son John to Nicephorus Bryennius, the husband of her daughter Anna. Having failed to persuade Alexius, or, upon his death, to carry out a *coup d'état* with the help of the palace guards, she retired to a nunnery and ended her life in obscurity.

3. IRENE (d. 1161), the first wife of Manuel Comnenus. She was the daughter of the count of Sulzbach, and sister-in-law of the Roman emperor Conrad III., who arranged her betrothal. The marriage was celebrated at Constantinople in 1146. The new empress, who had exchanged her earlier name of Bertha for one more familiar to the Greeks, became a devoted wife, and by the simplicity of her manner contrasted favourably with most Byzantine queens of the age.

IRETON, HENRY (1611-1651), English parliamentary general, eldest son of German Ireton of Attenborough, Nottinghamshire, was baptized on Nov. 3, 1611, became a gentleman commoner of Trinity College, Oxford, in 1626, graduated and entered the Middle Temple in 1629. On the outbreak of the Civil War he joined the parliamentary army, fought at Edgehill (1642) and at Gainsborough (1643), was made by Cromwell deputy-governor of the Isle of Ely, and next year served under Manchester, afterwards supporting Cromwell in his accusations of incompetency against the general. On the night before the battle of Naseby, in June 1645, he surprised the Royalist army and captured many prisoners, and next day was made commissary-general and appointed to the command of the left wing, Cromwell himself commanding the right. The wing under Ireton was broken by the charge of Rupert, and Ireton was wounded and taken prisoner, but after Cromwell's rout of the enemy he escaped. He took an active part in the campaign which resulted in the overthrow of the royal cause. On Oct. 30, 1645 Ireton entered parliament as member for Appleby, and while occupied with the siege of Oxford he was, on June 15, 1646, married to Bridget, Cromwell's daughter. He was opposed to the destructive schemes of the extreme party, disliked especially the abstract and impractical theories of the Republicans and the Levellers, and desired, while modifying their mutual powers, to retain the constitution of King, Lords and Commons. He urged these views in the negotiations of the army with the parliament, and in the conferences with the king, being chiefly entrusted with the drawing up of the army proposals. He endeavoured to prevent the breach between the army and the parliament, but when the division became inevitable took the army side. He aroused great suspicion by supporting the negotiations with the king. But becoming at length

convinced of the hopelessness of dealing with Charles, after the king's flight to the Isle of Wight he urged the parliament to establish an administration without him. Ireton served under Fairfax in the second civil war in the campaigns in Kent and Essex, and was responsible for the executions of Lucas and Lisle at Colchester. After the rejection by the king of the last offers of the army, he showed special zeal in bringing about his trial, was one of the chief promoters of "Pride's Purge," attended the court regularly, and signed the death-warrant. Ireton accompanied Cromwell in his Irish campaign, and was appointed major-general; on the recall of his chief to take the command in Scotland, he remained as lord-deputy to complete Cromwell's work of reduction and replantation. He was rapidly bringing his task to a close, when he died on Nov. 26, 1651 of fever after the capture of Limerick. His loss "struck a great sadness into Cromwell," for while he possessed high abilities as a soldier, and great political insight, he resembled in stern unflinchingness of purpose the protector himself. Ireton left one son and three daughters.

IRIARTE (or **YRIARTE**), **TOMÁS DE** (1750-1791), Spanish poet, was born in the island of Tenerife. His *Fábulas literarias* (1781), composed in a great variety of metres, show considerable ingenuity in their humorous attacks on literary men and methods; but their merits have been greatly exaggerated. During his later years, partly in consequence of the *Fábulas*, Iriarte was absorbed in personal controversies with Forner and others.

See E. Cotarelo y Mori, *Iriarte y su época* (1897).

IRIDACEAE (the iris family), in botany, a family of flowering plants belonging to the order Liliiflorae of the class Monocotyledons, containing about 800 species in 60 genera, and widely distributed in temperate and tropical regions. The members of this family are generally perennial herbs growing from a corm as *Crocus* and *Gladiolus*, or a rhizome as *Iris*; more rarely, as the Spanish iris, from a bulb. A few South African representatives have a shrubby habit. The flowers are hermaphrodite and regular as in *Iris* and *Crocus*, or with a symmetry in the median plane as in *Gladiolus*. The arrangement of the flower parts resembles that in the nearly allied order Amaryllidaceae (*Narcissus*,

FROM GROOM, "ELEMENTARY BOTANY" (G. BELL)

IRIS (IRIS PSEUDACORUS). LONGITUDINAL SECTION THROUGH FLOWER

Snowdrop), but differs in the absence of the inner whorl of stamens.

The most important genera are *Crocus* (q.v.), with about 60 species, *Iris* (q.v.), with about 200 and *Gladiolus* (q.v.), with 150. *Ixia*, *Freesia* (q.v.) and *Tritonia* (including *Montbretia*), all natives of South Africa, are well known in cultivation. *Sisyrinchium*, blue-eyed grass, is a new-world genus of 75 species, extending from arctic America to Patagonia and the Falkland Isles. One species, *S. angustifolium*, an arctic and temperate North American species, is also native in Galway and Kerry in

Ireland. Other British representatives of the family are: *Iris Pseudacorus* (yellow iris), common by river-banks and ditches, *I. foetidissima* (stinking iris), *Gladiolus illyricus*, a rare plant found in the New Forest and the Isle of Wight, and *Romulea Columnae*, a small plant with narrow recurved leaves a few inches long and a short scape bearing one or more small regular funnel-shaped flowers, which occurs at Dawlish in Devonshire. In the eastern United States there are 10 species of *Iris* and 13 species of *Sisyrinchium*, but in the Rocky Mountain region these genera are represented by only 2 or 3 species.

IRIDIUM, a metal found in small amounts in ordinary platinum ore, but generally obtained from the native alloy osmiridium. (Symbol Ir, atomic number 77, atomic weight 193.1.) The best method of obtaining it is that of Deville and Debray (see RUTHENIUM and OSMIUM), the process having been further simplified by G. Matthey (*Proc. Roy. Soc.*, 1879). The metal was first definitely identified by Smithson Tennant in 1804 (although other chemists, such as Descotels, Faucroy and Vauquelin, had previously indicated its separate existence) and was by him named iridium in consequence of the varying colour of its compounds. The metal is usually separated in the form of sparingly soluble ammonium iridium chloride, $(\text{NH}_4)_2\text{IrCl}_6$; this salt on ignition gives a residue of pure spongy iridium from which the massive form of the metal may be obtained by fusion. Iridium is a white metal possessing a lustre similar to that of steel; it is very hard and somewhat brittle when pure, but loses the latter property when alloyed with small quantities of other metals. It has the greatest density of any known substance (sp. gr.—22.4), and melts at about $2,260^\circ\text{C}$., volatilizing at a somewhat higher temperature. In the massive state the metal is practically insoluble in all acids, but in the spongy or finely divided condition it is attacked by aqua regia producing the higher chloride IrCl_4 .

Iridium is known to form two oxides, Ir_2O_3 and IrO_2 , which both act as bases forming salts with acids. The former is produced by igniting the finely divided metal in oxygen at a temperature below 800°C .; at a higher temperature decomposition into its elements results. The higher oxide is formed by gentle ignition of the corresponding hydroxide, $\text{Ir}(\text{OH})_3$. The salts of iridium are not of great importance. Two chlorides, IrCl_3 and IrCl_4 , are known, and with chlorides of the alkali metals these readily form double salts of the types M_2IrCl_6 and M_2IrCl_5 , most of which are easily soluble in water. Corresponding bromine compounds of iridium are also known, and at least three sulphides have been identified. Iridium forms many compounds with ammonia (see AMMINES) which in their properties are generally similar to those of the corresponding rhodium and platinum derivatives. The metal iridium is of considerable importance in industry, the chief use being in the form of platinum alloys. Platinum itself is a soft metal and as such is not suitable for general use. If, however, a small percentage of iridium is alloyed with it, the metal becomes very much harder, and hence ordinary platinum dishes, crucibles and weights always consist of a platinum iridium alloy, unless for special reasons pure platinum is necessary. The standard metre (*étalon*) is made of an alloy containing 90 parts of platinum and 10 parts of iridium (see PLATINUM). Iridium is also used to a small extent for producing a splendid black colour on china or porcelain. In magnetos, iridio-platinum is a necessity for contacts, screws, etc., as it resists the temperature of the electric spark much better than pure platinum. As a material for anodes in electrolytic reduction, platinum is the most suitable metal, but when the

electrolyte contains chlorides pure platinum undergoes corrosion and iridio-platinum alone is satisfactory. Iridium is always determined quantitatively by ignition of any of its salts and conversion into the metal. (F. E. M.)

IRIGA, a municipality (with 13 *barrios* or districts) of the province of Camarines Sur, Philippine islands, on the Bikol river, about 20 m. S.E. of Naga, the provincial capital, and near the south-west base of Mt. Iriga, a volcanic peak reaching a height of about 4,000 ft. above sea-level. It is on the railway running south from Manila through Naga. Pop. (1918), 24,145, of whom 11,955 were males and 18 whites. The soil in its vicinity is rich, producing rice, corn, sugar, pepper, cacao, cotton, abacá, tobacco and copra. Various valuable hardwoods are found in the nearby regions. In 1918, it had 11 manufacturing establishments with output valued at 100,000 pesos; three rice mills with output valued at 162,600 pesos; and 718 household industry establishments with output valued at 128,500 pesos. Eleven of the 12 schools were public. The language spoken is Bikol.

IRIS, in Greek mythology, daughter of Thaumás and the ocean nymph Electra (according to Hesiod), the personification of the rainbow and messenger of the gods; as a messenger of the gods, she is mentioned frequently in the *Iliad*, but never in the *Odyssey*, where Hermes takes her place. She is in Homer the messenger of both Zeus and Hera, but later the especial servant of Hera. By command of Zeus she carries in a ewer water from the Styx, with which she puts to sleep all gods who perjure themselves. Her attributes are the *caduceus* (herald's staff) and a vase.

IRIS. In botany, the iris plant belongs to the family Iridaceae of the class Monocotyledons; it is characterized by a petaloid six-parted perianth, an inferior ovary and only three stamens (the outer series), being thus distinguished from the Amaryllidaceae family, which has six stamens. They are handsome showy-flowered plants, the Greek name having been applied on account of the hues of the flowers. The genus contains about 200 species widely distributed throughout the north temperate zone. Two of the species are British. *I. Pseudacorus*, the yellow flag or iris, is common in Britain on river-banks, and in marshes and ditches. It is called the "water-flag" or "bastard floure de-luce" by Gerard; its flowers appear in June and July, and are of a bright golden-yellow colour. The other British species, *I. foetidissima*, the fetid iris, gladdon or roast-beef plant, the *Xyris* or stinking gladdon of Gerard, is a native of England south of Durham, and also of Ireland, southern Europe and North Africa.

In North America there are about 20 native species, found chiefly in the eastern United States; among the best known are the blue flag (*I. versicolor*) which grows in wet places from Newfoundland to Manitoba and southward to Florida and Arkansas, and the western blue flag (*I. missouriensis*), native to wet soils from North Dakota and New Mexico westward to California and British Columbia.

Iris florentina, with white or pale-blue flowers, is a native of the south of Europe, and is the source of the violet-scented orris root used in perfumery. *Iris germanica* of central Europe, "the most common purple Fleur de Luce" of Ray, is the large common blue iris of gardens, the bearded iris or fleur de luce and probably the Illyrian iris of the ancients. The garden plants known as the Spanish iris and the English iris are both of Spanish origin, and have very showy flowers. Along with some other species, as *I. reticulata* and *I. persica*, both of which are fragrant, they are great favourites with florists. All these just mentioned differ from those formerly named in the nature of the underground stem, which forms a bulb and not a strict creeping rhizome as in *I. Pseudacorus*, *germanica*, *florentina*, etc.

The iris flower is of special interest as an example of the relation between the shape of the flower and the position of the pollen-receiving and stigmatic surfaces on the one hand and the visits of insects on the other. The large outer petals form a landing-stage for a flying insect which in probing the perianth-tube for honey will first come in contact with the stigmatic surface which is borne on the outer face of a shelf-like transverse projection on the under side of the petaloid style arm. The anther, which opens towards

IRIS

the outside, is sheltered beneath the over-arching style arm below the stigma, so that the insect comes in contact with its pollen-covered surface only after passing the stigma, while in backing out of the flower it will come in contact only with the non-receptive lower face of the stigma. Thus an insect bearing pollen from one flower will in entering a second deposit the pollen on the stigma, while in backing out of a flower the pollen which it bears will not be rubbed off on the stigma of the same flower.

IRISH, the Celtic language of Ireland (*q.v.*), also called Erse. Old Irish (700–1100) contains a wealth of inflectional forms in declension and conjugation. Many of the forms, however, disappeared early. An interesting rule of vocalic harmony (slender to slender and broad to broad) is recorded. In Irish final syllables in general disappear except long vowels followed by *s* or *r* and *u/o* preceded by *i*. There were difficulties due to the insufficiency of symbols, and it is possible that popular speech moved rapidly ahead of the written language in phonetic developments. In Middle Irish the declensions and conjugations were much simplified. The neuter gender disappeared. In several respects the verbal system is developed as compared with the old Irish forms, details of which are given in standard grammars. Dialectal variations must have existed from early times, and while Leinster Irish has disappeared, there are still peculiarities distinguishing the Irish of Munster, Connaught and Ulster, the south being more conservative than the north. In the early period a number of loan words appear from Latin connected with the church or with articles of civilization. There are some of Norse origin. In the Middle Irish periods many French words were accepted. English has now provided a large number of words but the revival of Irish under the new political conditions should lead to further developments.

See J. Vendryes, *Grammaire du vieil-irlandais* (1908); R. Thurneysen, *Handbuch des Alt-Irischen* (1909), also *Revue Celtique* and *Zeitschrift für keltische Philologie*.

IRISH FREE STATE (SAORSTAT EIREANN). The Irish Free State, with the status of a British dominion, came officially into being on Jan. 15, 1922, when the Irish Peace Agreement, signed in London on Dec. 6, 1921, by the British and Irish delegations, already ratified by the British Parliament on Dec. 16, was adopted by a meeting of elected members of the parliament of Southern Ireland convened by Arthur Griffith. In 1923 the State was admitted a member of the League of Nations. The new State is composed of 26 of the counties and four of the county boroughs of Ireland. Its area is 17,019,155 statute ac., and its estimated population in 1926 was 2,972,802.

HISTORY

The treaty which led to the creation of the Irish Free State was concluded by the British Government with representatives of an Irish Government, which Great Britain had never recognized. From Jan. 1919, onwards, a large majority of the members of parliament elected for Irish constituencies had styled themselves Dáil Eireann—the Assembly of Ireland—had declared the Irish Republic in existence and had chosen a president and ministers. In May 1921, when elections were held under the Government of Ireland Act, 1920, Republican candidates were returned unopposed for all constituencies outside of Northern Ireland (except that of Dublin university) and for several constituencies in Northern Ireland. This, the second Dáil, met for the first time after the truce at the Dublin Mansion House on Aug. 16, 1921. All its members took the oath to the republic. Negotiations with Great Britain, at first conducted by E. de Valera, were resumed by a delegation headed by Arthur Griffith and Michael Collins. When the terms of the treaty were published on Dec. 6, 1921, de Valera announced his opposition. In the Dáil's debate, prolonged until Jan. 8, 1922, it was generally admitted that the country at large was for acceptance, but the treaty was accepted by the Dáil with a majority of only 64 to 57; and when de Valera resigned the presidency, Griffith was elected by only two votes.

The Provisional Government.—Under Article 17 of the treaty a provisional government was appointed at a meeting in which all members elected for constituencies in Southern Ireland

were summoned. Opponents of the treaty absented themselves. Eight men were named members of the Provisional Government, Collins being chairman. Griffith remained outside it. So did General Mulcahy, who became minister for defence. In theory the army was still the army of the republic, and the Provisional Government had no force at its disposal. The old constabulary was at once disbanded. Collins and his colleagues decided at once to form a new "Civic Guard," but it necessarily took time to organize, and its creators had decided in principle that it should be unarmed. British troops were rapidly evacuating the country. There was the Irish army, now largely in uniform; but it soon became clear that the army was a source of danger.

With the exception of Collins, only one man in the Provisional Government, Prof. Eóin MacNeill, was widely known in Ireland. Of the others, William Cosgrave, minister for local government, had been a prominent member of the Dublin Corporation from 1913 on, and in 1917 was returned as a Sinn Féin member of parliament. Duggan had been one of the signatories to the treaty. The others, K. O'Higgins, J. Magrath, F. Lynch and P. J. Hogan, were still young men with their careers yet to come.

Collins, a man of immense resource and energy, sought to strengthen his position by the reunion of Ireland. Under the treaty, if Northern Ireland consented, all powers retained in that province by the Parliament at Westminster would pass to the Parliament of the Free State. Interviews with Sir James Craig (Lord Craigavon), the Ulster prime minister, were arranged. Settlement was desirable for North as well as South, since in Belfast there raged a murderous strife between Catholic and Protestant; but no accommodation proved possible. Both Griffith and Collins desired a general declaration from the country by an election. But the Republicans, knowing as well as they what the result would be, resisted this, and de Valera called instead, on Feb. 21, a convention of delegates of the whole Sinn Féin organization. At this meeting, Collins consented to delay the election for at least three months and not to hold it till the draft of a constitution, based on the treaty, had been published.

Meanwhile, various acts of open disorder were committed in the name of the republic, which Collins, in hope of avoiding conflict, declined to punish. De Valera proclaimed at meetings that there was only one legitimate government in Ireland—that of the republic. The extremist Republican Party definitely desired renewal of war with England, and their armed bands still moved uncontrolled, levying toll from banks and commandeering motor-cars.

It appeared from his public utterances that President Griffith desired drastic action; but Michael Collins, the head of the Provisional Government, whose personal hold was stronger still, compromised, and on May 20 announced that he had reached agreement with de Valera. An election was to be held, but Free Staters and Republicans were to put forward a joint panel of candidates, so arranged as to reproduce the distribution of views in the existing Dáil. After the election a coalition ministry was to be formed, giving de Valera four seats in nine. The result of the election was not to be considered as a vote on the treaty. Appeal was made jointly that no other candidates be selected. But organized Labour insisted on putting forward candidates, and other interests took courage to follow their example. Michael Collins, at Cork, publicly advised the people to vote as they chose. There resulted some appearance of a free election in some constituencies, where the polling took place on June 16. Thirty-four candidates not on the agreed panel were elected—all supporting the treaty. The Republican defeat was evident.

CIVIL WAR

Several aggressive actions by the mutinous section of the army then followed, and on June 22 Sir Henry Wilson was murdered in London by two Irishmen who had served in the British army. The British Government made it clear that the Free State must act. A definite cause of action was afforded when the mutineers captured, in Dublin, the assistant chief of staff of the Free State army and held him as a hostage. On June 28 the Four Courts headquarters were summoned to surrender, and on refusal

PAINTED FOR THE ENCYCLOPÆDIA BRITANNICA BY ISABEL COOPER

TWELVE CULTIVATED VARIETIES OF IRIS

The iris family (*Iridaceae*) comprises about 1,000 species and has representatives throughout the temperate and tropical regions. Besides the familiar irises the family includes many other plants cultivated for ornaments, as gladioli, freesias and crocuses

TALL BEARDED IRISES: 1. Iris (*Plicata* type). 2. Iris (*Kochi*). 3. Hybrid Trojan iris (*I. trojana* x). 4. Iris (*Flavescens*). 6. Iris (*Neglecta* type). 8. Trojan iris (*I. trojana*). 9. Céleste iris. 11. Yemen iris (*I. albicans*)

BULBOUS IRISES: 5. Purple Spanish iris (*I. Xiphium*). 7. Dutch iris (*I. Xiphium hybridum*). 10. White Spanish iris (*I. Xiphium* var.). 12. Dutch iris (*I. Xiphium hybridum*)

siege was laid. After eight days' of localized fighting the struggle in Dublin was over. Rory O'Connor, who led the section in the army that demanded the right to be consulted on the terms of any settlement, was captured after he had blown up the Four Courts with all their records. De Valera, who had joined the insurgents, escaped.

Some districts of the country south and west were held by Republicans. The Government's army had neither a trained staff nor a system of supply. Five members of the Government took rank as generals, and Collins himself, flinging his whole energy into the struggle which he had so long sought to avoid, became commander-in-chief. But on Aug. 12 Arthur Griffith died suddenly. Ten days later, on the 22nd, Collins was killed in an ambush in the Co. Cork. Thus the task of establishing the Free State fell not to any man but to a group, the right wing of Sinn Féin.

Framing the Constitution.—It was necessary under the treaty that the third Dáil should as a provisional parliament frame a constitution which should also be adopted by the British Parliament before Dec. 6, 1922. On Sept. 9 it was possible to summon this body to meet in Leinster House, the premises of the Royal Dublin Society. In the adjacent College of Science the Government had established their offices. The block of buildings was placed under guard. None but carefully scrutinized representatives of the Press assisted at the nominally public debates. Under these conditions the Irish parliament and Irish government operated for nearly a year. Ministers lived as in a fortress.

At the Dáil's first meeting Cosgrave was elected president of the Irish Free State and he assumed the ministry of finance. Eleven ministers, proposed by him, were elected by the Dáil. The Dáil sat persistently to fulfil its task. The clauses of the constitution, which defined the relations between the Irish Free State and the British Crown and imperial defence, had been settled in discussion between Arthur Griffith and the British Government. Ministers had the task of persuading the Dáil to accept this limitation; they had also to put forward their own proposals for all that was left free.

The Restoration of Public Order.—By the end of Sept. 1923 at latest, there were no formed forces of the irregulars in the field, and all towns were held for the Government. Demand began to be heard for courts to which men could bring their cases. But the essential was to restore order. Property of all kinds was assailed. Whole bands of men in the name of the Republic were commandeering what they required. Much private robbery followed. More serious than all, the permanent land-hunger awoke.

Courts were long in being framed. The Civic Guard was being organized; but gunmen flouted, beat and in certain cases killed, members of this unarmed force. O'Higgins, minister for justice, however, stood resolutely to his principle: Ireland must be taught to regard the police, not as the agents of an outside power, but as its own servants, needing and deserving public assistance. The issue has justified his view; but for immediate purposes this body was useless. The Government on its side was driven, like the British, to enrol a large force of soldiers, which finally exceeded 50,000. This force, hastily levied, with officers as untrained as the men, did not always give satisfaction by its conduct.

Neither was Ireland, at the close of a movement extending over more than 40 years, easily able to support government in the face of terrorism; and terror was applied. The ministry was slow to counter this menace. Trial by jury was futile in such a state of things. The gaols were crammed with prisoners, untried and unpunished. Power to try and to punish most drastically by court-martial was given by an act of the Dáil; yet till November fear of the irregulars was stronger than fear of the Government throughout the country. At last a proclamation was posted announcing that four men had been tried, convicted and executed—in each case for having a revolver without licence. In the following week seven men were sentenced, on the same charge, to long terms of penal servitude. Thus the right of Government to deal at its will with persons in arms against the State had been asserted. But the irregular campaign of wreckage went on. More execu-

tions followed, among them that of Erskine Childers, who had been the most powerful influence over de Valera. There was no improvement perceptible by Dec. 6, when the Irish Constitution was formally ratified by both parliaments.

FORMAL INAUGURATION

Ratification completed, Northern Ireland notified the British Government by address of both houses of Parliament, that exercising its right under Article 12 of the treaty, it refused to come under the Free State, and desired to retain its position created by the act. The Free State being now formally constituted as a "Dominion," sensation was created by the appointment (Dec. 1922) of T. M. Healy, K.C. as its first governor general. On Dec. 8, when the Dáil assembled to choose a senate, as provided by the Constitution, President Cosgrave announced that one member of the Dáil had been shot dead and another wounded on the way to the meeting. Next morning four of the leading irregulars who were in prison were shot without trial by way of reprisal. Among them was Rory O'Connor. All these had been arrested long before the proclamation of martial law. General Mulcahy's justification was not given till some months later, when he pointed out that no other member of the Dáil had been attacked. In fact, the counter-terror succeeded. The country might now be terrorized into silence by the irregulars, but it gave them no such willing support as it had given to the Irish Republican army. Information came, surreptitiously but steadily, to the Free State troops. Further, in Dublin, where courts were now in session, juries did their duty fearlessly.

In nominating one half of the members of the Senate, President Cosgrave made good the promise given by President Griffith to leading Irish Unionists that they should be generously treated: his nominations comprised several leading landlords and other prominent Protestants. The Senate when constituted chose as its chairman Lord Glenavy, who as Sir James Campbell had been Sir Edward Carson's chief lieutenant.

The gravest danger was that foreseen by Michael Collins when he pointed out that criminal folly might destroy "our belief in ourselves as a nation." There was an orgy of destruction, which almost paralysed communication by road and rail; houses were burnt or bombed by dozens, and the Government, once started on their path of severities, pursued it ruthlessly. By the end of January executions had risen to 50, and the prisoners to 10,000. No government could be popular under such conditions. Yet signs of weakening began to show. By May 1923, de Valera called upon his followers to abandon hostilities and dump their arms in concealment. The sound of firing was no longer heard in the streets, and public meetings were once more held. When August brought the annual horse show, ministers were seen moving freely in the crowd. The resumption of normal civic life may be dated from this time.

In April the Free State, still maintaining and collecting the British system of taxes, found it necessary to set up a customs system at the ports and along the Ulster border. The first object was merely ascertainment of revenue, but the machinery for a protective tariff existed. In June the minister for agriculture introduced a measure for the completion of land purchase, and this was carried through hastily. The third Dáil, which had passed the constitution, still existed, but a general election on the new register with adult suffrage was fixed for the last days of August. The Government's action had exposed it to much odium. Some 10,000 prisoners were detained in gaol, mostly untried, and over 70 men had been executed. Yet President Cosgrave, Mr. O'Higgins and General Mulcahy were returned by huge majorities at the head of the group in which they stood. But de Valera also headed the poll in County Clare and the Republicans returned no less than 44 members out of 128. Government had in its own following less than half the Dáil. But the various groups of Independents were notably increased. All these supported the treaty and the constitution.

The New Government.—Ireland's accession to her new status was practically signified on Sept. 10, 1923, when her representatives took their place with acclamation in the Council of the

League of Nations. A month later Cosgrave attended the Dominion Conference in London, where he was warmly welcomed. At home the executive council was for the first time constituted, consisting of seven. Four other ministers were chosen as "extern," having individual, not collective, responsibility. Ernest Blythe, who now became minister for finance, had at once to face a serious situation. It had become clear that the State would not be destroyed by violence—there was fear lest it should be bankrupt. Civil war had produced damages, then reckoned at £50,000,000, though, when compensation came to be paid, the bill reduced itself to about ten. But the army was costing over £14,000,000 a year, and taxation stood at the peak point to which Great Britain had raised it. In December the Government came to the country for a loan of £10,000,000 at 5%—the issue figure being 95, repayable at par in 20 years. It was oversubscribed in ten days, the subscribers numbering over 22,000. This demonstration of confidence greatly cheered the country, and rounded off the satisfaction felt in comparing the settled order of Christmas 1923, with the ruinous anarchy in which the year opened.

Yet the year 1924 was a very unhappy period. Organized resistance to the State was withdrawn, but de Valera's followers refused to surrender or hand in their arms. There was much crime, especially robbery with violence. The army, so rapidly raised, was reduced, for motives of economy, with equal rapidity, and men were suddenly thrown out of employment. A bad harvest in 1923 had left acute financial depression, and work was scarce.

Legislation.—Added to this was the unpopularity of the Government's measures. Blythe reduced old age pensions from ten shillings to nine shillings. Taxation was severely levied; tenants in default with their land purchase annuities were forced to pay up; citizens who had withheld their income tax during the last years of the British administration, with Sinn Féin's approval, were now called upon for their arrears. More widely felt was the innovation of a customs barrier, causing delay in the delivery of goods; and, in addition, Blythe decided to embark experimentally on a measure of protection, its main feature being a duty of 15% on imported boots.

In framing the new judicial system, the number of judges and their salaries were reduced, the office of lord chancellor disappeared; a supreme court was constituted, and a high court, both sitting in Dublin. High court judges no longer went on circuit; a new order of circuit judges was instituted. As regards the magistracy, unpaid justices of the peace were abolished, and stipendiary district justices were appointed to cover the whole country.

Judges of the previous régime were free to retire on rather more than four-fifths of their salary, and most of them did so. In making the new appointments the Government showed a fine disregard of political record, and totally ignored religious differences. By 1925, five out of the nine high court judges were Protestants, and several had been strong Unionists. The effect of this was to confirm the allegiance already promised by the minority in the Free State; and leading members of it, notably divines of the Church of Ireland and of the Presbyterian Church, offered testimony to the impartiality of the Government.

People were forced to see that no alternative to it existed, and ministers showed little disposition to win support by conciliating public feeling. O'Higgins forced on a drastic bill to restrict the facilities for buying and selling drink; Burke, the new minister for local government, by simple administrative act suppressed the corporations of Dublin and Cork and put civic affairs into the hands of commissioners; and presently, when the commissioners produced improved administration and reduced the inordinate rates, this experiment was approved. Outside the towns, the ministry abolished district councils, thus throwing more work on the county councils. A tendency to centralization and even to bureaucratic administration showed itself in all directions.

Such a policy made enemies everywhere, and the weather was no friend to Cosgrave. A second bad season in 1924 hit the farmers hard, and Blythe was still levying taxes that were now actually higher than the British scale; for the reduction of income tax from 5s. to 4s.6d. in 1924 was not followed in the Free State. The new postmaster greatly cut down the public facilities, and

kept the stamp at twopence. If there had been any alternative ministry the Government would have fallen, but there was none; and the bellicose protestations of Republicans kept them in power. Another thing assisted them: when a turn in English politics replaced a Labour Ministry by a strong Tory Government, English ministers kept faith absolutely with Ireland.

BOUNDARY TROUBLES

The Boundary Commission.—No step had been taken until 1924 to give effect to the provision in Article 12 of the treaty under which, if Northern Ireland decided to remain outside the Free State a commission of three was to be appointed to "determine in accordance with the wishes of the inhabitants, so far as may be compatible with economic and geographical considerations, the boundaries between Northern Ireland and the rest of Ireland." But with the cessation of civil war Cosgrave's Government was pressed to demand its application. Immediately threats came from Ulster of resistance by force to the cession of a single inch of territory. Ramsay MacDonald attempted to settle the matter by private negotiations, but this failed. The Free State named Prof. MacNeill as their representative on the commission, but Northern Ireland refused to recognize the commission in any way. MacDonald appointed Justice Feetham, a South African judge, as chairman, but Northern Ireland contended that its own refusal to appoint a representative would make the constitution of the commission void. The difficulty was referred by the Labour Government to the judicial committee of the Privy Council, which found that without a new act of Parliament enabling the Imperial Government to appoint a commissioner to represent Northern Ireland nothing could be done.

Parliament was summoned on Sept. 30 instead of on Oct. 28, as had been originally intended, in order to pass through its stages the Irish Free State (Confirmation of Agreement) bill, which had been introduced by the Government at the end of the session. The defeat of the Labour Government on another issue was not allowed to prejudice the Irish settlement, and just before the dissolution the bill received the royal assent. A well known publicist, from Ulster, was appointed; and the commissioners, after long preliminaries in London, proceeded to investigate opinion on the border itself during several months in 1925 without the least disturbance. In the meanwhile, from many quarters, but notably from Cosgrave and his ministers, came utterances to the effect that there was no intention of coercing Ulster. She must choose her own time for uniting, if she chose, with the rest of Ireland. This indicated a departure from the expectations held out by Michael Collins after the treaty was signed, for he had led Ireland to hope that the commission's award would transfer so much territory to the Free State that Northern Ireland would not be able to maintain its separate status.

At the opening of 1925 Blythe's budget of April marked the beginning of normal finance. It soon became apparent that the ministry was not proposing a mere negative policy of economy, and early in 1925 they committed themselves to a project for utilizing the Shannon (*see SHANNON*) for a considerable electric power scheme. Nor did this stand alone. By promise of a subsidy amounting to a total of over £1,000,000 a Belgian firm was induced to start the sugar beet industry on a large scale, Carlow being chosen as the site for the central factory. Simultaneously came a whole group of proposals for the development of Irish industry and Irish agriculture, which had been interminably discussed in and out of Parliament during the British régime. They stood committed to a policy of industrial development, having as the pivot of the whole an enterprise so colossal that its possibility had never even been seriously considered under the old order. In the meantime tranquillity returned to the country so completely that it seemed dull. Tourists refilled their old haunts in summer; the Dublin Horse Show enlarged its scope.

The Ulster Boundary Crisis.—In the late autumn a new crisis threatened the Government's prestige and even existence. The report of the boundary commission was awaited without emotion, though a London newspaper published a forecast of its decision differing widely from any anticipations that had been formed

in the Free State. There was a fierce outcry, and President Cosgrave reiterated the Free State's contention that the commission was only entitled to transfer to their natural destination those parts of the six counties whose inhabitants desired to be in the general body of Ireland. These declarations were followed by the announcement that the Free State representative had withdrawn from the commission. Prof. MacNeill followed this up by resigning his post on the executive council.

Both the Government and Prof. MacNeill were attacked with great violence in the Dáil and outside it. The Republican leader came into new prominence. Cosgrave refused to commit himself publicly to any line of action, and went to London, where negotiations proceeded. Sir James Craig was summoned from Ulster; and on Dec. 3, a new agreement was concluded, to which not only Great Britain and the Free State were parties, but Northern Ireland also. It was agreed that the award of the commission should not be published and that the existing boundary should stand. This gave to Ulster all that Ulster claimed, but it gave to Ireland the repose of finality. Further, the treaty was altered by the cancellation of Article 5, under which Ireland assumed liability for the public debt of the United Kingdom as existing in 1921 "in such proportion as may be fair and equitable, having regard to any just claims on the part of Ireland by way of set off on counter claims." This at once liberated the Irish exchequer from an undefined, hanging liability injurious to its borrowing power. Ireland, however, undertook to repay to Great Britain compensation already paid for war damages in the period 1919-21, and to add 10% to the compensation awarded to claimants for damages suffered in the civil war from 1922 on. The total cost to Ireland was estimated at under £5,000,000.

Legislation embodying the terms of this agreement was carried without difficulty in Great Britain, and the Northern Parliament expressed its satisfaction. But in the Dáil President Cosgrave was angrily opposed by the Labour Party and by some of his own followers, and after much talk the bill was carried by 71 to 20. Business men as a whole regarded the issue as fortunate for Ireland, which now definitely became a country with a total national debt of under £20,000,000 and less than a year's gross revenue. Other sections found their chief satisfaction, as did President Cosgrave, in the changed relation of the governments concerned. An immediate consequence was the disbandment of the Ulster special police in two of its three branches.

The Imperial Conference.—Freed from these long-standing anxieties, the fourth Dáil made steady progress with the work of reorganization, and extended the foundations of further economic development. In the spring of 1926 questions of external affairs and imperial relations occupied considerable attention. The Free State's membership of the League of Nations had brought definite responsibilities for the prevention of future wars; and the approach of the Imperial Conference turned the attention of the Government towards a fuller insistence upon the international rights of the Free State. A conflict over appeals from the Irish courts to the Privy Council, the position of the governor general, the question of passports for Irish citizens in foreign countries, and other questions affecting the international status of the Free State, were vigorously canvassed before the Imperial Conference met in the autumn. When the conference assembled, Kevin O'Higgins, who had already assumed a more prominent part in the representation of the Free State at the League of Nations, quickly became one of its most important figures. His insistence upon a fuller definition of the rights inherent in dominion status found strong support among some of the other dominions, and had a profound influence upon the decisions which the conference reached.

GOVERNMENTAL PROGRESS

Reconstruction.—By the spring of 1927 the Dáil could look back upon four years of solidly constructive work as the general elections approached. McGilligan, in introducing the Electricity Supply bill, reported very satisfactory progress with the Shannon scheme. Hogan was able to report an immense improvement in the prospects of Irish trade owing to the Government's enforce-

ment of an official grading of exported butter and eggs; and he introduced a bold measure for giving long term credits to farmers to supplement the facilities offered by the banks. Blythe's budget for 1927 announced that the Government now felt it safe to reduce the estimate of normal army expenditure by £500,000; and with the assistance of certain economies he was thus able to lower the income tax to below the English level, at 3s. in the pound.

Within four years nearly 200 acts had been passed by the fourth Dáil, and the foundations of the new State had been laid, while all the compensation claims arising before the Anglo-Irish truce had been dealt with, and only 400 out of some 20,000 subsequent claims still remained. Members of all parties gave expression to their sense of a new comradeship acquired during the work of the Dáil and congratulated each other on the rapid growth of a parliamentary tradition which had produced new feelings of mutual respect and confidence.

At the elections held in June the strong desire for a change of government after the first trying years of the new State was clearly manifest. The smaller parties which criticized the Government on various grounds gained in strength, and Cosgrave came back at the head of a party of 46 instead of 57, unable to command a majority in the Dáil. No other party, however, found itself able to form a government, and Cosgrave consented to resume office on the clear understanding that he would pursue his own programme until the other parties agreed to defeat his ministry.

Murder of Kevin O'Higgins.—Then, to the consternation of the whole country, on July 10, Kevin O'Higgins, the vice-president of the executive council, was assassinated outside his house near Dublin. The Republicans immediately disclaimed responsibility for, or sympathy with, his murder, but Cosgrave expressed the popular indignation and horror by denouncing it as a deliberate attack upon the State. The Government, unable to trace the authorship of the crime, sought drastic powers by the new Public Safety Act, which proclaimed all revolutionary societies as being treasonable and gave powers to arrest or deport suspected persons, in addition to introducing the death penalty for any treasonable offence.

Holding the Republicans responsible for having encouraged acts of murder, the Government also introduced a bill designed to force the Republican deputies to enter the Dáil, by prescribing an oath of willingness to enter the Dáil and also the oath of allegiance to the Constitution, for every candidate at future parliamentary elections. De Valera exhausted every effort to defeat the passage of the bill, and finally, in despair, consented to lead his party into the Dáil at once. They agreed at last to take the oath of allegiance, while proclaiming in advance that they all regarded it as an "empty formula" which would not bind their actions in any way. An agreement was quickly reached with the Labour Party and with Capt. Redmond's National League to out-vote the Government on a motion of no confidence, on the understanding that Johnson was to assume office with the support of the Republicans. When the motion was debated on Aug. 16, it was anticipated that Cosgrave would be in a minority of one, but the disappearance of Alderman Jinks at the last moment enabled the Speaker to save the Ministry by his casting vote.

In such circumstances a second general election was obviously inevitable. Cosgrave awaited the results of two by-elections in Dublin, which both gave him large majorities, and then suddenly announced a dissolution before any party could prepare for an election or replenish its funds. The election resulted in a drastic reduction of the smaller parties, Cosgrave winning many seats from the Farmers' Party and the National League, and de Valera many more from the Labour Party. The sixth Dáil assembled on Oct. 11, with Cosgrave's party of 61 still in a minority of the Dáil, and with the Republicans' strength increased to 57.

The Sixth Dáil.—But with the support of the Farmers' Party and the Independents, against a combination of Republicans, Labour Party and National League, Cosgrave could count on a safe majority of six votes, and he did not hesitate to accept office. On the first division in the Dáil the Labour Party voted with the Government, and a little later de Valera's effort to repeal the Public Safety Act was defeated by a majority of six. The first

serious business of the Government was to float a new loan of £7,000,000, at the same price of issue as before. The general belief that de Valera's accession to office would shake public credit had been the chief deterrent to a change of Government; which in spite of all that Cosgrave's ministry had accomplished, had long been desired, in view of the widespread unpopularity that the Government had inevitably incurred by its vigorous enforcement of the law and its policy of drastic retrenchment. For the first time the Dáil now included all its elected deputies, and contained an alternative government in the Republicans, who had not only agreed to take part directly at last in the development of the Free State, but had pledged themselves to act on constitutional lines.

1928.—For some months work in the Dáil was impeded by acrimonious debates, and in the new year de Valera, having obtained the necessary number of signatures, demanded that a referendum on the abolition of the oath of allegiance should be taken. Cosgrave retaliated by introducing a bill to abolish the provisions for referendum and for initiative of legislation contained in the constitution. The Republicans, seeing that defeat was inevitable, adopted systematically obstructive tactics. By the autumn of 1928, however, a growing sense of co-operation in the work of the Dáil was perceptible. The Republicans took part in several joint committees of all parties; and although they stubbornly resisted Cosgrave's decision to adopt the majority recommendations for a different form of election to fill the triennial vacancies in the Senate, they took advantage of the resulting opportunities, and secured the return of their full quota of candidates in the election in October. The Government had in January exercised its right, which had been conceded at the Imperial Conference of 1926, to choose the successor to Mr. T. M. Healy as governor general. Mr. James McNeill, who had been High Commissioner in London, was appointed. In November the creation of two new Irish embassies, in Paris and Berlin, was announced, and Professor Smiddy was transferred from Washington to replace Mr. McNeill in London. Professor Smiddy was succeeded by Mr. Michael MacWhite, who took office on March 24, 1929.

(S. G.; D. G.)

THE CONSTITUTION

The present political status of the Irish Free State is that of a co-equal member of the community of nations forming the British Commonwealth. It has a written constitution which rests on the provisions of an act passed by Dáil Eireann sitting as a constituent assembly in the autumn of 1922.

It is provided in this act that the Constitution shall be construed with reference to the treaty between Great Britain and Ireland, and that if any provision of the constitution or of any amendment thereof or of any law made thereunder is in any respect repugnant to any of the provisions of the treaty, it shall, to the extent of such repugnancy, be void and inoperative. It is also provided that to the extent to which they are not inconsistent with the constitution all laws in force in the Free State at the time of passing of the constitution are to continue to have full force and effect until repealed or amended by the Oireachtas.

In conformity with practice in the British Commonwealth the executive authority is vested in the king. The governor general represents and fulfils the functions of the Crown. He is appointed "in like manner as the governor general of Canada and in accordance with the practice observed in the making of such appointments." His powers are strictly limited as in the case of the Sovereign in Great Britain, all executive acts being done on the advice of the executive council. The latter consists of not more than 12 nor less than five ministers, and is directly responsible to Dáil Eireann, retiring from office when it has lost the support of a majority of deputies.

Dáil Eireann may not at any time be dissolved except on the

advice of the executive council, and Article 53 provides that the Oireachtas shall not be dissolved on the advice of an executive council which has ceased to retain the support of a majority in Dáil Eireann. The maximum life of a parliament is six years. The president of the executive council, who is appointed on the nomination of Dáil Eireann, nominates the executive council. Other ministers, not members of the executive council, may be appointed on the nomination of committee of Dáil Eireann, and these ministers are directly and individually responsible to the Dáil for the administration of their departments. Members of the executive must be members of Dáil Eireann, but this provision does not apply to other ministers. The legislature, known as the Oireachtas, consists of the king and two houses, Dáil Eireann (the Chamber of Deputies) and Seanad Eireann (the Senate). In the Oireachtas is vested "the sole and executive power of making laws for the peace, order and good government of the Irish Free State."

The Senate.—Seanad Eireann is composed of 60 members, the term of office of each member being 12 years. One-fourth of the members are elected every three years by proportional representation, the whole of the Free State forming one electoral area. At every election a panel of candidates is formed, consisting of three times as many persons as there are senators to be elected. Two-thirds of the panel is nominated by the Dáil and one-third by the Seanad. Any former senators may be added to the panel if they so desire. Candidates, who must have reached the age of 35 years, are chosen on the ground that they "have done honour to the nation by reason of useful public service or that, because of special qualifications or attainments, they represent important aspects of the nation's life." Casual vacancies in the Seanad are filled by co-option, who retire at the next election.

The Chamber of Deputies.—Dáil Eireann (the Chamber of Deputies) is composed of members directly elected on the system of proportional representation by constituencies determined by law. The number of members was fixed at 153. This number may, however, be varied from time to time, but shall not be fixed at less than one member for each 30,000, or more than one member for each 20,000 of the population of the state. In addition the two universities each elect three members.

All citizens of both sexes who have reached the age of 21 and who comply with the electoral laws, may vote for members of Dáil Eireann, and all citizens who have reached the age of 30 years and who comply with the electoral laws may vote for members of Seanad Eireann. Voting is by secret ballot, and no voter may exercise more than one vote at any election.

Members of both houses receive an allowance for expenses which is fixed at £360 per annum. Every member of the Oireachtas must take the following oath before taking his seat:—

I do solemnly swear true faith and allegiance to the constitution of the Irish Free State as by law established, and that I will be faithful to H. M. King George V., his heirs and successors by law, in virtue of the common citizenship of Ireland with Great Britain and her adherence to and membership of the group of Nations forming the British Commonwealth of Nations.

Powers of the Senate.—Seanad Eireann has no authority to amend a money bill, but may make recommendations to Dáil Eireann regarding such bill within 21 days after a bill certified to be a money bill has been passed by Dáil Eireann. The definition of a money bill given in Article 35 of the Constitution is adopted from the United Kingdom "Parliament" Act of 1911. There is a proviso that the decision of the chairman of Dáil Eireann as to whether the bill is or is not a money bill may be appealed against before a committee consisting of three members of each house presided over by a judge of the Supreme Court. The Seanad may reject or amend all other bills, and may initiate legislation, but a bill passed by the Dáil which has not been passed by the Seanad 270 days after it was first sent to the Seanad, is deemed to have been passed by both houses in the form in which it was last passed by Dáil Eireann. Any bill passed or deemed to have been passed by both houses may be suspended for a period of 90 days on the written demand of two-fifths of the members of Dáil Eireann, or of a majority of the members of Seanad Eireann presented to the president of the executive council not later than

seven days from the day on which such bill shall have been so passed or deemed to have been so passed. During the period of suspension the bill shall be submitted to a referendum if so demanded by one-twentieth of the voters on the register or by three-fifths of the members of the Seanad. These provisions do not apply to money bills or to bills declared by both houses to be necessary for the immediate preservation of the public peace, health or safety.

Defence.—The Oireachtas has the exclusive right of raising and maintaining armed forces in the Free State, but under the provision of the treaty the army shall not exceed in size such proportion of the army in Great Britain as that which the population of Ireland bears to the population of Great Britain.

Nationality, etc.—Every person domiciled in the Free State at the time of the coming into operation of the Constitution, who was born in Ireland or either of whose parents was born in Ireland, or who has been ordinarily resident in the area of the jurisdiction of the Free State for not less than seven years is entitled to citizenship in the Free State. Freedom of conscience and the free profession and practice of religion are, subject to public order and morality, guaranteed to every citizen. No law may be made to endow any religion or to give any preference or to impose any disability on account of religious belief. No discrimination may be made as respects State aid between schools under the management of different religious denominations.

Court of Appeal.—The Supreme Court of the Free State is a court of final appeal and its decision cannot be reviewed by any other court, tribunal or authority whatsoever, provided that nothing in the constitution shall impair the right of any person to petition His Majesty for special leave to appeal to His Majesty in council or the right of His Majesty to grant such leave.

Amendments.—Article 50 gives power to the Oireachtas to make by ordinary legislation any amendment of the Constitution within the terms of the treaty during the first eight years; and a number of amendments have already been passed. A Government Bill was introduced in October 1928 to extend the time limit which prevents any further amendments after 1930 without confirmation by a referendum.

The first amendment resulted from the agreement in London in 1925 to cancel Articles 5 and 12 of the treaty. In Dec. 1926 the Government introduced and carried without a division four minor amendments. The proposal to return the speaker unopposed to sit in the next Dáil without representing any constituency, whether he was re-elected as speaker or not, was amended in the Senate, which obtained the Government's consent to its compromise proposal that the speaker should be automatically re-elected for the same constituency as before, but that the constituency should elect one member less. The second amendment has abolished the public holiday prescribed for the polling day of each general election. The third extends the maximum term of office of Dáil Eireann from four years to six. The fourth has increased the membership of the executive council from seven to twelve.

Several amendments were carried in 1927 in connection with the attitude of the Republican party. They were compelled to enter the Dáil by the imposition of the oath of allegiance, and of a declaration of willingness to sit in the Dáil, for all candidates in elections. To prevent the holding of a referendum on the oath of allegiance and to nullify the petition for initiative of legislation to the same effect, the provisions for referendum and for initiative were soon afterwards removed from the Constitution. Various amendments affecting the Senate were carried in 1928 before the triennial elections to fill one-third of its seats. Instead of election by the whole country as one constituency, vacancies are now filled by the Dáil and Senate voting together; candidates being chosen from a panel to which each House elects as many candidates as there are vacancies. The age limit for senators has been lowered from 35 to 30 years. Powers of the Senate to delay legislation have been increased to 18 months, after which there can be a further delay of two months if the Dáil carries the same legislation again. The term of office of senators has been reduced from 12 to 9 years.

See J. G. Swift McNeill, *Studies in the Constitution of the Irish Free State* (1925).

ECONOMIC AND FINANCIAL HISTORY

The area of the Free State is 17,024,642 statute acres, of which 15,619,044 are under agricultural holdings. The area ploughed, the area under hay and the area under grass are respectively 1,551,447, 2,287,849, and 8,416,439 acres. The valuation of the urban districts is £2,779,846 and of rural districts £8,715,022, the total valuation being £11,494,868.

Population.—The last census of Ireland was taken in 1926. The population of the Free State was 2,972,802, or 5.3% less than in 1911.

In 1926 the number of marriages registered was 13,570, being 4.57 per 1,000 of the population; the number of births was 61,176, being 20.6 per 1,000 of the population; and the number of deaths was 41,740, being 14.05 per 1,000 of the population. While the reduction in the mortality from tuberculosis has been steady and continuous for many years, the death rate from cancer is increasing. Of the total deaths at all ages 16.2% were deaths of children under five years of age, and the number of deaths of infants under one year was equivalent to a rate of 7.4 of the birth rate. Infantile mortality is decreasing.

Practically no emigration took place from Ireland during the World War. It is estimated that the number of emigrants to "places out of Europe and not within the Mediterranean sea" was 15,000 in 1922, 20,570 in 1923, 19,077 in 1924, 30,302 in 1925, and 30,359 in 1926. Of the emigrants in 1926, 26,367 were bound for the United States, 1,994 for British North America, 1,268 for Australia, 236 for New Zealand, 166 for British South Africa, 109 for India and 219 for other countries. The population of the Free State is overwhelmingly rural. There are only two towns with more than 50,000 inhabitants, namely, Dublin and Cork, and two others with more than 20,000, namely, Limerick and Waterford.

In 1911 the population of the 26 counties now forming the Free State contained 2,812,509 Roman Catholics, 249,535 members of the Church of Ireland, 45,058 Presbyterians and 3,805 Jews. The great majority of the population were English-speaking, but 16,869 spoke Irish only, and 536,348 were bilingual. Of persons aged nine years and upwards, 260,694 could neither read nor write, and 74,001 could read but could not write. The number of houses in the 26 counties in 1911 was 642,541, or one house for 4.88 inhabitants.

Agriculture.—The total acreage under crops on June 1, 1927, was 3,694,285. The following are figures of acreage under crops and numbers of live-stock in the Free State in 1926–27:—

	1926.	1927.
<i>Crops</i>		
Wheat	29,386	34,446
Oats	647,407	644,610
Barley	141,009	120,796
Rye	6,645	6,055
Flax	6,802	5,998
Potatoes	374,771	364,639
Turnips	104,600	183,213
Mangolds	80,839	79,804
Sugar-beet	9,483	17,698
Cabbage	34,428	30,871
Hay	2,287,849	2,183,086
<i>Live-stock</i>		
Cattle	3,947,249	4,048,430
Sheep	3,003,080	3,120,637
Pigs	884,216	1,177,037
Goats	189,439	185,810
Horses	424,304	428,614
Asses	199,172	196,925
Poultry	21,366,801	21,575,798

There are 442,606 agricultural holdings, of which 86,033 are less than one acre, 223,991 above one and not exceeding 30ac., 130,807 above 30 and not exceeding 500ac. and 1,775 above 500 acres. Official figures show that the percentage of land ploughed varies inversely with the size of the holding; that for equal areas of crops and pastures, the number of live-stock (especially milch cows, pigs and poultry, and excepting sheep) rapidly increases as the size of the holding diminishes; and that the larger the per-

centage of land tilled, the larger the number of animals supported.

The cultivation of cereal crops plays a comparatively unimportant part in the agricultural economy of the Free State, and the bulk of the attention of the farmer is devoted to the raising of stock. As between the production of beef and of dairy produce, conditions vary in different parts of the country. In certain areas dairy breeds, in others beef breeds, are predominant. The type of cultivation favoured by the soil, climate and prevailing holding is extensive. The percentage of the total area ploughed is 12.7% as compared with 56.7 in Denmark, and the net value of agricultural exports per 1,000ac. is £11,227 as compared with £4,939 in Denmark.

In accordance with detailed recommendations made by the commission which reported in 1924, an act was passed (No. 35 of 1924) providing for the testing, grading and packing of exported eggs, for the prohibition of the export of dirty or bad eggs, and for the registration of all premises where grading, packing or preserving is carried on. Another act (No. 58 of 1924) made elaborate provision for the regulation of the butter trade. Butter can now be exported only by registered creameries, factories or exporters, and must be packed and marked in a specified manner. The most minute regulation of creameries and factories is insisted on, and provision is made for the establishment at a later date of a national mark or brand for creamery butter. A federation of co-operative creameries has been established with the aim of introducing a system of "orderly marketing" of butter, and the majority of the privately owned creameries have been purchased by the State and transferred to co-operative societies. The dairy industry has thus been rationalized. The licensing of bulls was made compulsory by another statute (No. 3 of 1925). This measure, together with the Government's scheme for providing premium bulls and boars and for subsidizing the purchase of pedigree rams, has resulted in levelling up the standard of the live-stock in the country.

The Government has set up an agricultural credit corporation designed to provide long-term loans for farmers and to co-ordinate the activities of the local co-operative credit societies. Other measures taken to develop agriculture are the increase of the grant in aid of agricultural rates, the provision of higher agricultural education in the National University and the undertaking of extensive arterial drainage.

Land Purchase.—The total amount of the purchase money for which advances have been made under the Land Purchase Acts of 1870-1909 in respect of lands in the Free State is £99,800,000, the total area comprised in the sales being 11,290,000 acres. The land commission also advanced £3,796,000, to rural district councils for the erection of labourers' cottages under the Labourers' Acts.

The Land Act of 1923 aimed at attaining the dual object of completing land purchase and relieving congestion. This act provided for the creation of land bonds, bearing interest at the rate of 4½%, in which all payments to landlords and encumbrancers were to be made. These bonds were later guaranteed, as to principal and interest, by the British Government. Advances made to purchasers were to be repaid by an annuity at the rate of 4½% of the amount advanced, and the price to be paid was roughly equal to about 15 years' purchase of the value of the holding, of which the Government contributed 10% in relief of the tenant. Very wide powers were given to the land commission to acquire untenanted land for the creation of holdings in relief of congestion, and to consolidate and exchange holdings with the same object.

The area of untenanted land already acquired by the land commission and the late congested districts board and utilized for the relief of congestion amounts to 860,000 acres. Advances were authorized to be made to tenants of uneconomic holdings, tenants exchanging their holdings, persons who had been evicted and labourers who had lost their employment through the progress of land purchase. The money required by the land commission for making roads, fences, drains, etc., and for the erection of buildings on newly created holdings is provided out of public funds, and so much as the land commission decides can be repaid by the

purchasers is made repayable by them along with their purchase annuities. All arrears of rent due before the first gale day of 1920 were remitted; but rent due after that date (subject to 25% reduction) was made recoverable.

It is estimated that advances amounting to £30,000,000 will be required to complete land purchase under the 1923 Act. As regards tenanted land, holdings situated on 6,000 estates have to be dealt with, while as regards untenanted land, the land commission has inspected or is making enquiries in respect of 1,000,000 ac., with a view to their acquisition for the purpose of distribution; and of this area the land commission has acquired or entered into agreements for the acquisition of over 250,000 acres. Of the untenanted land acquired 130,000ac. have been already divided among allottees.

Fisheries.—The work formerly done by the department of agriculture and the congested districts board in connection with fisheries and with rural industries has now been transferred to a separate ministry, whose policy is to develop the deep-sea fisheries and to organize the home demand for fish, which is at present very small. The Government is helping the fisheries by making loans for boats and gear, erecting and maintaining curing stations, and subsidizing fishery schools. A brand for mackerel has been instituted. One urgent requirement is being delayed for financial reasons, namely, a second patrol boat to keep the coast free from the numerous foreign trespassers who at present infest it. In 1927 the land commission was transferred to the ministry of fisheries.

INDUSTRY AND TRADE

Manufactures.—Ireland was, even before partition, an overwhelmingly agricultural country, but the predominance of agriculture became greater than ever after the exclusion of the six counties. The agricultural commission reckoned that three-quarters of the real wealth produced in the Free State is farm produce. Too great dependence upon any one industry is always undesirable, and the Government has taken steps to redress the unequal balance between the agricultural and manufacturing industries.

The treaty left the Free State at liberty to frame its tariff policy as it chose. There was a widespread popular belief that Irish industry could best be revived by the adoption of a high protective tariff, and the Government appointed a small committee of economists to enquire into the probable effects of protective duties. The report of this committee was strongly free trade in tone. It pointed out the numerous factors, besides external competition, that operated to retard the growth of industry in Ireland. The necessity for a dominantly agricultural country of the lowest possible prices of raw material and consumable commodities was pointed out. Nevertheless the Government proceeded to institute a number of experiments in protection.

On the setting up of the customs barrier in April 1923 the manufacture of tobacco automatically secured protection. The Finance Act of 1924 imposed a duty of 3½d. per lb. on sugar confectionery, of 6d. per lb. on cocoa preparations, of 10% *ad valorem* on candles, 15% *ad valorem* on boots and shoes, 33½% on glass bottles (not white glass) and 10% *ad valorem* on soap. The McKenna duties were altered so as to provide encouragement for the building of commercial motor bodies, and the imperial preference on manufactured tobacco was abolished. The Finance Act of 1925 went a good deal farther in the same direction, but the minister for finance declared that the new duties were purely experimental in nature. This act imposed a duty of 15% *ad valorem* on clothing, wearing apparel, blankets and blanketing, and 33½% on bedsteads and wooden furniture; the duty on bottles was extended, and an additional duty of 10% was put on toilet soaps. In 1926 a duty of 2s. 6d. per cwt. was imposed on imported oatmeal, and in 1927 duties of 33½% on rosary beads and of 3d. per lb. on margarine. All applications for protection are now heard by a tariff commission composed of three civil servants representing respectively the ministries of finance, agriculture and industry and commerce. This commission has rejected the application for a duty on imported flour.

At the same time some important revenue duties were abolished or reduced. It would appear, however, from the cost of living index numbers that the result of the new tariff (in conjunction with other causes, such as a bad system of retail distribution) has been to prevent the cost of living in the Free State from being reduced at the same rate as in Great Britain. This is shown by the following table:—

Cost of Living Index Numbers
(Basis: July 1914 = 100)

Year.	Free State.				Great Britain and Northern Ireland.			
	Jan.	April.	July.	Oct.	Jan.	April.	July.	Oct.
1922	..	191	185	189	192	182	184	178
1923	190	181	180	186	178	174	169	175
1924	188	178	183	193	177	173	170	176
1925	195	188	188	188	180	175	173	176
1926	188	180	182	189	175	168	170	174
1927	182	171	171	175	175	165	166	167

In addition to giving the protective assistance outlined above, the Government has endeavoured to encourage industry by means of subsidies, the development of cheap sources of power, and the provision of credit facilities. The growth of sugar-beet and the manufacture of beet-sugar were encouraged by the grant of a subsidy payable for ten years to persons manufacturing in the Free State sugar from home-grown sugar-beet. A large Belgian-Czechoslovakian group, encouraged by the subsidy, opened a sugar-beet factory in Carlow. The result of the first year's working was successful beyond all expectations.

An important attempt is also being made to provide the Irish manufacturer with cheap power. The Government sought the advice of Messrs. Siemens-Schuckert, who drew up a scheme for utilizing the great water power of the Shannon. Another method by which the Government attempted to encourage industry was by helping enterprises to obtain capital on easy terms under the Trade Loans Guarantee Act (No. 41 of 1924). The maximum amount that might be advanced under Government guarantee under the act was fixed at £750,000. The minister was further authorized to grant or to guarantee loans proposed to be raised by any public authority or any association of producers or consumers "calculated to promote a reduction in the retail prices in Saorstát Éireann of essential commodities." The maximum grant under this action was limited to £50,000, and the maximum grant and guarantee together to £250,000. By an amending act (No. 19 of 1925) the period in which this assistance might be rendered was extended; and the Finance Act of 1925 provided for the advance of £300,000 to the National Land Bank for the purpose of trade loan guarantees.

An Industrial Trust Company designed to provide long-term credits for manufacturers has been established, part of the capital being subscribed by the State.

Banking.—All the banks having their head offices in the Free State have numerous branches in Northern Ireland, and two of the Belfast banks have numerous southern branches. Shortly after the treaty, the Belfast bank, which is affiliated with the Midland bank, sold its branches situated in the Free State to the Royal Bank of Ireland. More recently the Bank of Ireland absorbed the National Land Bank. The Government's banking business is transacted by the Bank of Ireland. The deposits of the six Free State banks amounted in 1927 to £127,798,000 as against £133,035,000 in 1926, and the amount of the Dublin clearings in 1927 was £253,817,000, an increase of £3,798,000 on 1926. The Currency Act (No. 32 of 1927), which was based on the recommendations of the banking commission, provides for the establishment of a separate currency to be managed by a currency commission independent of Government control. The legal tender note will be backed pound for pound by gold, British notes or British Government securities, and will be convertible into sterling on demand. There will also be a bank-note issue limited in amount to £6,000,000 which will not be legal tender. The Free State currency will thus be "anchored to sterling." The first national loan, both as regards principal and interest, is repay-

able in sterling, as are also the bonds created under the Land Purchase Act.

Trade.—The following are the imports and exports of the Irish Free State, the figures indicating hundreds of thousand £'s.—

Year.	1924.	1925.	1926.	1927.
Imports	68,890	62,950	61,386	60,826
Exports	51,535	44,382	41,956	44,852
Balance	17,355	18,568	19,330	15,974

The invisible items are approximately estimated as follows: exports, including dividends on foreign investments, remittances from the United States, British war pensions, etc., £17,000,000; imports, including land purchase annuities payable to the British Government, pensions to ex-police and civil servants resident abroad, etc., £8,000,000.

Communications.—In 1914 there were in Ireland 28 railway companies operating 3,454 miles of line. The Irish railways were placed under the control of the British Government in 1917 and were released in Aug. 1921, a few months before the treaty. During the control period, the net receipts for 1913 were guaranteed, and on the cessation of control the Government paid the railways £3,000,000 in full settlement of all claims. Meanwhile, wages had been raised by about 200%, while freight and passenger rates had been raised only by 120% and 100% respectively. The resulting difficulties led to the Railways Act of 1924, modelled on the British Act of 1921, for amalgamating all the lines situated wholly in the Free State. On Jan. 1, 1925, came into being the new Great Southern railway, comprising all the companies in the Free State, but excluding the Great Northern railway (Ireland), which is partially situated in Northern Ireland. The traffic receipts of the Great Southern railway in 1927 were £4,247,244, an increase of £61,210 on 1926.

The conditions which prevail in the Free State render the competition of the road vehicle very formidable; the average journey is short, and many places in the country are several miles from a railway station. The number of motor vehicles licensed in 1926 was 44,962 and in 1927, 45,774.

TAXATION AND FINANCE

In the following table can be found the revenue and expenditure of the Irish Free State for each year from 1922 to 1928:—

Year.	Receipts.	Expenditure.
	£000s.	£000s.
1922-23	27,863	29,595
1923-24	31,414	38,687
1924-25	26,948	27,937
1925-26	25,439	26,693
1926-27	25,060	27,392
1927-28	29,123	29,080

The deficits shown in the above table were mainly accounted for by the extraordinary non-recurrent expenditure arising out of the military expenses and compensation incurred in respect of the civil war of 1922-23. In addition a large amount of expenditure of a capital nature on the Shannon scheme and other productive projects has been met out of current expenditure.

Public Debt.—In Nov. 1923 the Irish Free State floated its first loan. The nominal amount raised by this loan was £10,000,000. The interest offered was 5% and the issue prices 95, the flat yield being thus about 5½%. The loan is redeemable at par between 1935 and 1945. The loan was a great success, being oversubscribed in the Free State; no part of it was underwritten or taken by the banks. Provision was shortly afterwards made for the satisfaction of persons who had contributed to the official Sinn Féin loans floated during the Anglo-Irish fighting. Irish subscribers were to receive savings certificates, and subscribers elsewhere were to have their holdings redeemed. In 1927 the second national loan was floated. The amount raised was £7,089,175 (nominal), the price of issue 97 and the rate of interest 5%. £3,082,250 of this issue was raised in the United States as a

dollar loan and holders of the Irish issue have the right to transfer into the American issue at a fixed rate of exchange. The price of the national loans in Feb. 1928 was 100 and of compensation stock 97½. The agreement made between the British and Free State Governments in Dec. 1925, provided that the outstanding liabilities of the Free State under the treaty in respect of the British National Debt should be settled by an annual payment of £250,000 for a period of 60 years. A further and final agreement made in March 1926 provided for the liquidation of all outstanding liabilities between the two Governments. The public debt amounts to about £20,000,000.

Taxation.—The system of taxation in operation at the time of the treaty was taken over, and, owing to the difficult financial situation created by the civil war, no reductions were attempted for a couple of years. In the years 1923–24 and 1924–25 the income tax was maintained at the rate of 5s., and the corporation profits tax was retained. In both these respects the Free State taxes were higher than the British. The budget of 1924 reduced the super tax on very high incomes, and reduced the tea duty from 8d. to 5d. per pound. In 1925 the income tax was reduced to the British rate of 4s., and the exemption limit to corporation profits tax was raised. The duty on sugar was considerably reduced and imperial preference in that commodity discontinued, and the duties on tea, coffee, cocoa and chicory were abolished. In 1927 the income tax was reduced to 3s. The relief which the taxpayer might have derived from these concessions was to some extent counterbalanced by the burden of the new protective duties.

In addition to the sums raised by national taxes, the following sums were raised by local taxation: year ending March 1922, £6,762,672; March 1923, £4,153,060; March 1924, £5,327,341; March 1925, £5,310,550; March 1926, £5,296,977. The total (national and local) taxation amounts (1928) to about £10 per head of the population.

DEFENCE

Historical.—Immediately after the ratification of the Anglo-Irish Treaty in January 1922, British troops began to withdraw from Free State territory, and soon afterwards the Irish regiments included in that territory, with a magnificent fighting record, were withdrawn from the British Army. In the terms of the treaty it was agreed that responsibility for defence by sea both of Great Britain and of Ireland should be undertaken by Imperial forces, and that the Irish defence forces should not exceed, in their military establishments, the proportion to the British army which the population of Ireland bears to the population of Great Britain. The question of Irish participation in coastal defence was postponed for five years. The civil war which followed the withdrawal of British troops and the mutiny of March 1924 brought about some changes in the administration of the Free State army, of which full details are given below.

Recruitment and Service.—Recruitment is based upon voluntary enlistment, from the age of 18 onwards, for periods up to

12 years' service, of which periods of 1 month up to 3 years in the infantry, and up to 5 years in other arms, are spent with the colours. The Minister of Defence has the power to vary the terms of service; and re-engagements up to 21 years, with the right to discharge on three months' notice, are permitted. All soldiers, on completion of their term of service with the colours, if shorter than the term for which they originally enlisted, are transferred to the reserve. Reservists can be called up for training for 30 days in any one year. They can be called up for permanent service in the event of imminent national danger, but not for more than 12 months over the unexpired portion of their time in the reserve. Until the expiry of 5 years after the establishment of the Military College, the following will be eligible for appointment to commissions in the Irish Free State army. (a) Citizens of the Irish Free State, (b) officers and men serving in the army, (c) such other persons as the minister may approve. After the 5 years, preference in appointment to commissions will as far as possible be given to Military College graduates. £5,000 was allowed in the Budget for 1927–28 for military training of officers abroad.

Strength, Organization and Higher Command.—The Budget effectives in 1927–28 numbered 12,753, including 833 officers up to the rank of Lieutenant General. The organization is in 27 battalions of infantry, grouped in 9 brigade areas; 4 armoured car companies; two battalions of artillery; various engineer units (5 companies, one of them a training company, and a depot); army medical services; military police (5 companies and 4 detention barracks); a signal corps of 5 companies; and army transport companies.

The ministry of defence is charged with administration, discipline and control of the military defence forces. Under the minister, there is a council of defence presided over by himself as "commander-in-chief." There are three military members, the Chief of Staff, Adjutant General and Quartermaster General and a civil member, member of *Dail Eireann*, as finance member and parliamentary secretary to the minister. Under the ministry of defence, the Irish Free State is divided into four military districts, each forming a separate command. These are No. 1, Western Command; No. 2, Southern Command; No. 3, Eastern Command; No. 4, Curragh Training Camp.

Each military district contains a certain number of brigade areas, of which at present (1928) there are nine, each with its own headquarters. The Curragh training camp contains schools of instruction for officers and for non-commissioned officers, and a reception and training depot.

Besides the afore-mentioned Irish Military College, and schools of instruction at the Curragh, there is an army school of music. There are special training companies at the Curragh for engineers, medical services, signals and army transport.

Excepting in certain coast defences still occupied, in accordance with the terms of the treaty with Great Britain, by small garrisons of British troops, there are no modern permanent fortifications in the Irish Free State.

The *Garda Siochana*, or unarmed Civic Guard was in 1925 amalgamated with the Dublin Metropolitan Police. The combined force so formed has a maximum establishment strength of 6,454, including 192 officers.

The Army Air Corps includes a headquarters and one squadron. See also *League of Nations Armaments Year-book* (Geneva, 1928). (G. G. A.)

IRISH LITERATURE. The English occupation of Ireland raised its first literary monument in the *Kildare Poems* of the early 14th century whose interest is now mainly philological. Up to the middle years of the 16th century the use of English was limited to a few towns and to the confines of the Pale. It was not until the close of the next century that the conflicting policies of the two countries produced a special colonial spirit, whose spokesman was Molyneux, and a literature of corresponding character, Irish to the English, English to the Irish. This Janus-faced attitude of Anglo-Irish literature lasted almost into our own period, injuring its artistic integrity by its partisan spirit. In the 17th century the author of the *Hiber-*

niad proudly counts Swift, Denham, Parnell, Farquhar, Steele, Southerne, Roscommon, Boyle, Ussher and Berkeley amongst the Irish authors of his day. Only of the two greatest of these, Swift and Berkeley, may it be fairly said that their life in Ireland left a deep impress on their work. Ireland taught Swift his fierce hatred of injustice and that deep compassion for material suffering which Lecky observes. The same spectacle of Irish conditions added to Goldsmith's incomparable charm a sense of social values which lifts him above the urbane and artificial poets, and it gave to Burke the passion for justice which glows in his political philosophy. A strong Irish accent marked the thought as it marked the speech of both men. These men were born into the violent contrasts of the Irish 18th century where the most artificial inequalities of status and political control maintained a brilliant and corrupt society in the capital, firing the eloquence of Grattan and Curran and pointing Sheridan's wit.

Thomas Moore.—Into this strife, too, was born Thomas Moore (1779-1852) whose *Irish Melodies* had in their day a European vogue and were acclaimed by the greatest of his contemporaries. His practice of writing to music necessarily betrayed him into a diffuse and cloying sweetness, and writing before the Wordsworthian reaction his language and imagery are often out-moded. But he remains a master of swift, light and musical verse as well as of witty political satire. His control of varied metres restored to the English lyric the freedom of 17th century verse. In this he was an innovator as well as in his introduction of certain Irish modes to English metre. With him for the first time there entered into Anglo-Irish poetry some faint breath of the Gaelic spirit which is the vital force of its later development. The cadences and imagery of Gaelic poetry give whatever is of value to the folk-verse of Callanan (1795-1829) and Walsh (1805-50), and the scholarly George Darley (1795-1846) dipped his pen in the same glittering honeydew. Its influence is supreme in the visionary James Clarence Mangan (1805-49), whose genius let and hampered, as has been said, by inborn physical and spiritual sensitiveness, reached in his best work the highest lyrical levels. Lionel Johnson, a kindred soul, ranks Mangan's "Dark Rosaleen" with the great lyrics of the world where the chivalry of a nation's faith is struck of a sudden into the immortality of music. His "Nameless One" has the troubled and vehement sincerity of Villon and Byron. At this time O'Curry, O'Donovan and Petric were laying the foundations of Gaelic scholarship but with slight influence. Mangan excepted, upon the poets of their day.

The writers of *The Nation* newspaper, Duffy, D'Arcy McGee and the rest who followed the fruitful plough-share of Thomas Davis (1814-45) were pre-occupied with the Repeal and '48 movements and the work of politics. Literature was to them a tool and not an end in itself. Similarly, the new scholarship touched but did not greatly affect the impersonal and meditative Aubrey de Vere (1814-1902). Denis Florence McCarthy, the translator of Calderon, or John Auster the translator of Faust. But as the fruits of their studies ripened, Sir Samuel Ferguson (1810-86) found Irish themes to fit "the epic largeness of his conception" and he revealed to the younger poets the harvest about their feet.

Gaelic Influence.—The modern school traces its ancestry back in this way through Ferguson and Mangan to the Gaelic poets. The way to their ancient founts was pointed by the scholars already mentioned and by their successors, Whitley Stokes, Standish Hayes O'Grady, Kuno Meyer, Dr. Sigerson, Dr. Douglas Hyde and the editors of the Gaelic poets of the 17th and 18th centuries. Particular importance attaches to the publication of Hyde's *Love Songs of Connacht* and his edition of Raftery which notably influenced the new school in the direction of folk-simplicity, and to the works of Standish O'Grady, second of that name, who influenced it in the contrary direction by the glamour with which he invested the older heroic literature. The emergence of this group about 1900 was the literary evidence of a resurgent national spirit as race-conscious in literature as the Gaelic League in education, or Sinn Féin in politics. It had its origin in this race-consciousness stimulated by the study of the

old heroic literature and of the folk poetry which still existed in Irish. It might have been a phenomenon of merely political or antiquarian interest if its chiefs were not primarily artists.

W. B. Yeats worked to a standard of well-nigh perfect artistry and the writings of George Russell (A.E.) were deepened and generalized with a profound consciousness of the divine origin and destiny of man. Yeats's interest in magic and A. E.'s pantheism remove their work still further from the kingdoms of this world. Yeats has always been a highly self-conscious artist. His early work broods in sorrowful ecstasy over visionary beauty; his later work is more austere in form, deliberately fashioned into abstract simplicity, very personal and often petulant. About these two writers and the Abbey theatre, the Gaelic League and Sinn Féin, were grouped in diverse relations the poets, novelists and dramatists of the so-called Irish literary revival. Ethna Carbery impersonated its spring-tide, Alice Milligan its clean-cut masculine purpose; there were nature poets like Katharine Tynan and Francis Ledwidge; poets of the people like Padraic Colum. Joseph Campbell, Moira O'Neill; town poets like Seumas O'Sullivan who introduced a new and mordant note into his fastidious art; the newcomers, Austin Clarke, whose imagination is fitly exercised in epic subjects, F. R. Higgins, who seeks to develop the subtle Gaelic mode in clarity, and Oliver Gogarty, a writer of witty and lapidary verse. Reaction from cloudy abstraction and a transition to prose marked the passing of youth and the coming of age of the movement. The appearance of James Stephens may be taken as the turning point, who passes indifferently from verse to prose, from slum idylls to the riotous invention of the *Crock of Gold* and *The Demigods*, and exhibits at each turn the same leaping fancy and the same wise and witty humanity.

Fiction.—The politics which became prose literature under Swift's pen remained literature in the hands of Wolfe Tone (*Autobiography*), Mitchel (*Jail Journal*) and Padraic Pearse, but the novel had a later start. Maria Edgeworth (1767-1849), the earliest of Anglo-Irish novelists, still remains a central figure amongst them. Equalling any of her successors in the vivacity of her dialogue and in the fidelity of her character studies she brought to bear on Irish life a criticism more serious and candid than any of the group after her. Samuel Lover (1797-1868) redeems with a touch of poetry his inclination to buffoonery. Charles Lever (1806-72) excels in the rollicking novel of adventure. He rarely touches serious issues but fills his pages with the "half-sirs" and "squireens" who swarmed in Ireland up to the date of the Incumbered Estates Act. He fashioned out of this class a pseudo-national figure of the hard-drinking, devil-may-care Irishman, and succeeded in impressing it on his foreign readers as the national type. The once popular Lady Morgan enjoyed a social and political vogue, and the singular figure of Maturin, whose influence Balzac admitted, will always hold the attention of literary historians. Of more importance is the group which includes the Banim brothers (John, 1798-1842; Michael, 1796-1824), and the charming idyllist of peasant life, Charles Kickham (1826-82). With their knowledge of the people, but not without a sentimental and idealizing tendency, they penetrated the surface upon which Lever's school was content to play. With better models and technical equipment this period might have produced an Irish Turgeniev. Between the frivolous and the idealists stands the considerable figure of Carleton (1794-1869), a twisted genius of unusual intensity, the opposite of Maria Edgeworth in all points, his blind power, grotesque humours and native, uncertain art contrasting with the security of her judgment and technique. Emily Lawless and Jane Barlow continue the study of the Irish peasant with the seriousness of their age, and contemporary with them the two writers who, under the names of Somerville and Ross, reproduce the laughing surface of Irish life in the true rhythm of Anglo-Irish speech—all three with a poet's sensitiveness to the changing beauty of the Irish landscape. The modern novelists, George Moore at their head, range themselves less consciously along the lines drawn by the religious and agrarian struggle of the 19th century. They are more pre-occupied with their art than with politics. The realism of the early Moore and of *The Real Charlotte* fortifies but does not displace the creative imagination of

which James Stephens is the exemplar. Daniel Corkery's short stories and his single novel, *The Threshold of Quiet*, are studies of intense though quiet reality with which may be mentioned Colum's *Castle Conquer*. The premature death of Seumas O'Kelly was a great loss to Irish literature. His *Weaver's Grave* is the best modern Irish short story. Post-war conditions explain the brutal and immature talent of O'Flaherty whose short stories deserve recognition. There remains the unique personality of James Joyce, who passes the bounds of Anglo-Irish, if not indeed of English, literature.

The Literary Theatre.—The history of the Irish theatre begins in the mid-17th century and the stage was firmly established in the 18th when Garrick and Mrs. Siddons were welcomed in the rivalry of genius with the native Spranger Barry and Peg Woffington. Congreve was contemporary in Dublin with Farquhar who made his first appearance as an actor in the famous Crow street theatre, and on them followed Goldsmith and Sheridan—the twin glories of the 18th century stage. Macklin, O'Keeffe, Gerald Griffin and Dion Boucicault carry on the succession into the 19th century when the supremacy of Dublin, and Ireland, in this field is resumed first with the brilliant and unhappy Oscar Wilde and in our day with Bernard Shaw and the Abbey dramatists. The movement which resulted in the foundation in 1904 of the Abbey theatre began in the meeting of the writers Russell and Yeats with the actors W. G. and Frank Fay. It was a fortunate junction of poets with actors who sought in simplicity for truth. The first plays were heroic and poetical. With the accession of Synge (1871–1909) the movement received its most powerful impulse. He founded no school; his tragic imagination was not hereditary and his gift of richly imaged speech could not safely be imitated. Lady Gregory contributed comic verse, inexhaustible invention and an instinct for cumulatively absurd dramatic situation. These, with Padraic Colum, were the foundation dramatists. Colum, with his social sense and grave beauty of speech, was the first begetter of the peasant drama; his best play *Thomas Muskerry* was produced in the year of Synge's death and it is to his idiom rather than to Synge's that later dramatists returned. The new writers include T. C. Murray, Lennox Robinson, St. John Ervine and Lord Dunsany. Murray uniformly shows a strong sense of dramatic situation, the technique of an accomplished artist and a faculty for significant and beautiful speech. Lennox Robinson is master of easy, graceful dramatic conversation while the highly personal talent of Lord Dunsany exhibits itself in unusual invention and verbal felicities. Sean O'Casey's first play was staged in 1923. His advent is significant of the vitality of the movement and its change. The heroic play in verse or prose has given place to the drama of realism, and the townsman is challenging the peasant's monopoly of the stage. O'Casey has a consummate power of creating and energizing character, a speech that holds rich local savour without losing its natural rhythm, pity and humour that transcend the squalor of the slums. In these gifts and in his passion for truth, the fruit of enthusiasm and disillusion, lies his promise. (C. P. Cu.)

Gaelic

In the absence of a native coinage it is extremely difficult to say when the use of letters was introduced into Ireland. It is probable that the Latin alphabet first came in with Christianity. With the exception of the one bilingual Ogam inscription as yet discovered in Ireland (that at Killeen Cormac) all the inscriptions in Roman letters are certainly later than 500. With regard to the Ogam inscriptions we cannot make any confident assertions. Owing to the lack of criteria for dating certain Irish sound-changes accurately it is impossible to assign chronological limits for the earlier stones, which cannot be later than the 5th century, but there is nothing to show whether they are Christian or not. The Ogam system is certainly based on the Latin and not the Greek alphabet, and was probably invented by some person from the south of Ireland who received his knowledge of the Roman letters from traders from the mouth of the Loire.

Early Irish Mss.—The great bulk of Irish literature is contained in mss. belonging to the Middle Irish period (1100–1550),

but it will be convenient for us to deal first with those documents which are termed Old Irish. Most of the Old Irish documents have been printed by Stokes and Strachan in the *Thesaurus Palaeohibernicus*, and where no reference is given the reader is referred to that monumental work. The extraordinary outburst of intellectual activity in Ireland from the 6th to the 9th centuries and the compositions of Irishmen in the Latin language, belong to the history of mediaeval European literature and fall outside the scope of this article. For the *Confessions of St. Patrick* and his "Letter to the Subjects of Coroticus" see PATRICK. The only Irish document ascribed to the saint is the strange so-called "Hymn," the *fáeth fiada*, more properly *fóid fiada*, "the cry of the deer." This hymn, which contains a number of strange grammatical forms, is undoubtedly referred to in the Book of Armagh, and may very well go back to the 5th century. The date of the Irish hymns in the *Liber Hymnorum* ranges, according to Stokes and Strachan, from the 7th to the 11th centuries. Ultán's hymn on St. Brigit beginning "*Brigit bé bithmaith*," which is by far the most artistic of the collection, was perhaps composed in the 7th century. Definite metrical laws had evidently been elaborated when this poem was written. The beat is iambic, but the natural accent of the words is rigidly observed. The long line consists of two units of five syllables each. The rhymes are dissyllabic and perfect. Alliteration is always observed in the latter half of each line and assonances are found knitting up the half-lines. The well-known hymn on St. Patrick traditionally ascribed to Fiacc, bishop of Sletty, and the piece beginning *Sén Dé*, traditionally ascribed to Colmán, are assigned on linguistic grounds to the beginning of the 9th century. The Patrician documents by Muirchu Maccu Machthéni, who professed to write at the command of Bishop Aed of Sletty (d. 698), and by Tirechán, who is said to have received his information from Bishop Ultán (d. 656), are contained in the Book of Armagh, a ms. compiled by Ferdomnach in 807.

The earliest pieces of connected prose in Irish are three:—(1) the Cambray Homily, contained in an 8th-century codex at Cambray: the language dates from the second half of the 7th or the beginning of the 8th century; (2) the additions to the notes of Tirechán on the life of St. Patrick in the Book of Armagh; these seem to go back to the early 8th century; (3) the tract on the Mass in the Stowe Missal, which is in all probability nearly as old as the Cambray Homily. Of especial interest are the spells and poems found in the Stowe Missal and two Continental mss. A St. Gall codex has preserved four Irish incantations of the 8th and 9th centuries. The 9th-century codex preserved at the monastery of St. Paul in Carinthia contains several interesting short poems in Irish.

For our knowledge of the older language, however, we have to rely mainly on the numerous glosses scattered about in a large number of mss., which it is impossible to enumerate here. It will be sufficient to mention the three most important codices containing Old Irish glosses. These are as follows:—(1) The Codex Paulinus at Würzburg. The date of this highly important ms. is much disputed; part of the Irish glosses seem to date from about 700, whilst the rest may be placed a little before 800. (2) The Codex Ambrosianus, formerly at Bobbio, now at Milan; these glosses were copied in the first half of the 9th century. (3) Glosses on Priscian contained in four mss. The other chief texts or authors provided with Irish glosses are Augustine, Bede, the Canons, the Computus, Eutychius, Juvenius, Philargyrius, Prudentius and Servius. The Milan and the St. Gall codices just mentioned both contain several short poems in Irish.

Two ponderous religious poems have now to be noticed. To Oengus the Culdee is attributed the lengthy *Féilire* or Calendar of Church Festivals, consisting of 365 quatrains in *rinnard* metre, one for each day in the year. The language of this dry compilation, which is heavily glossed and annotated, points to 800 as the date of composition, and Oengus, who is stated to have lived about that time, may well have been the author.

It may perhaps be as well to enumerate here the later Irish martyrologies. (1) The *Martyrology of Tallaght*, founded on an 8th-century calendar, but containing additions down to 900 (ed.

D. H. Kelly, 1857). (2) The metrical *Martyrology of O'Gorman*, c. 1166-74, edited by Stokes for the Bradshaw Society (1895). (3) The *Martyrology of Donegal*, an important compilation in prose made by Michael O'Clery in 1630, edited by J. H. Todd (1864). A composition which is wrongly assigned to Oengus the Culdee is the *Saltair na Rann* or Psalter in Quatrains, published without a translation by Stokes (1883). The work proper consists of 150 poems, but 12 poems have been added, and in all it contains 2,098 quatrains. This psalter received additions as late as 998. We should perhaps also mention here the famous *Amra* or Eulogy of St. Columba, commonly attributed to Dallán Forgaill, a contemporary of the saint, but Stokes takes the view that it was written in the 9th century, and is intentionally obscure.

During the 9th and 10th centuries Ireland was harassed by the Vikings, and a host of scholars seem to have fled to the Continent, carrying with them their precious books, many of which are preserved in Italy, Switzerland, Germany and elsewhere. Hence very few early Irish mss. are preserved in Ireland itself. When the fury of the storm was past, Irish scholars showed increased interest in the old literary documents, and copied all that they could lay hands on into miscellaneous codices. The earliest of these collections, such as the *Cin of Druim Snechta*, the *Yellow Book of Slane*, the *Book of Dubdaleithe*, the *Psalter of Cashel*, exist no longer, though their names have come down and certain of them were known in the 17th century. However, copies of a goodly portion of the contents of these old books are preserved to us in one form or another, but mainly in a series of huge miscellaneous codices ranging in date from the 12th to the 16th century. The oldest is *Lebor na h-uidre*, which we shall abbreviate as LU., preserved in the Royal Irish Academy and published in facsimile (1870) by the Academy, which is also publishing the entire text of this codex in Roman letters marking the different handwritings. This ms. was compiled in part in the monastery of Clonmacnoise by Moelmuire Mac-Celechair, who was slain in 1106. LU. is almost entirely devoted to romance, the stories which it contains belonging mainly to the Ulster cycle. The next ms. in point of age is the Book of Leinster (abbreviated LL.) now in Trinity college, Dublin, which was transcribed by Finn, son of Gorman, bishop of Kildare (d. 1160), and also contains a large number of romances in addition to other important matter bearing more particularly on the affairs of Leinster. The Yellow Book of Lecan (YBL.), also in Trinity college, Dublin, was written at different times by the MacFibis family, and it also contains a vast amount of romance. The most extensive collection of all is the Book of Ballymote (BB.), now belonging to the Royal Irish Academy, which was compiled about the beginning of the 15th century by various scribes. In 1522 it was purchased by the O'Donnells for 140 milch cows. The contents of the *Leabhar Breac* (LB.), or Speckled Book, now in the Royal Irish Academy, are chiefly ecclesiastical and religious. All these five codices have been published in facsimile by the Royal Irish Academy with a description of their contents. Two important Mid. Ir. mss. in the Bodleian (Rawlinson B 512 and Laud 610) are also published in facsimile by Henry Frowde.

Other mss. which require special mention are (1) The Great Book of Lecan, compiled in the year 1417 by Gilla Isa Mór MacFibis, in the Royal Irish Academy, for whose chequered history see the Marquis MacSweeney's article R.I.A. (1928). (2) The Book of Lismore, the property of the duke of Devonshire at Lismore castle, whose contents are described in the introduction to Stokes's *Lives of Saints from the Book of Lismore* (1890). (3) The Book of Fermoy in the Royal Irish Academy. The contents are described in the introduction to O'Beirne Crowe's edition of the *Táin Bó Fraich* (1870). (4) The Book of Hy Maine now in the Royal Irish Academy. The scribe who wrote it died in 1372. O'Curry, O'Longan and O'Beirne Crowe drew up a ms. catalogue of the Irish mss. in the Royal Irish Academy, completed by Purton in over 30 ms. volumes. The Academy has since published in 1927-28 three fasciculi of a new catalogue by O'Rahilly, Miss Mulchrone and Miss Byrne. O'Donovan performed the same service for the Trinity college, Dublin, collection.

A briefer account of the Irish mss. in TCD. will be found in Abbott's and Gwynn's Catalogue of the mss. in that library. O'Curry also drew up a list of the Irish mss. in the British Museum, and S. H. O'Grady printed part i. of a descriptive catalogue of this collection (1901). Robin Flower completed this catalogue in 1926. The mss. in the Franciscan monastery in Dublin are described by J. T. Gilbert in the *Fourth Report of the Royal Commission on Historical MSS.* W. F. Skene catalogued the collection of mss. in the Advocates' Library, Edinburgh, a printed catalogue of which has been issued by D. Mackinnon (1909; see also *Trans. Gaelic Soc. of Inverness*, xvi. 285-309).

O'Curry states that if the five oldest vellum mss. were printed the result would be 9,400 quarto pages. Other mss. ranging in date from 1300 to 1600 would fill 9,000 pages of the same size. D'Arbois de Jubainville, published in 1883 a tentative catalogue of Irish epic literature. He mentions 953 Irish mss. containing epic matter preserved in Irish and English libraries. To these have to be added another 56 in Continental libraries.

The language in which the huge miscellaneous codices enumerated above are written is called by the general name of Middle Irish, which is a very wide term. Irish scribes often copied their original somewhat mechanically, without being tempted to change the language to that of their own time. Thus in many parts of LU. we find a thin Middle Irish veneer on what is largely Old Irish of the 8th or 9th century, and it may even happen that a 14th or 15th century ms. such as YBL. contains much older forms than a corresponding passage in LL.

The "Fili."—It remains for us to say a few words about the *fili*, the professional literary man in Ireland. The *fili* (from the stem *vel-*, "to see," Welsh, Breton, *gwelet*, "to see") appears to have been originally a diviner and magician, and corresponds to the *vates*, *oiváreis*, of the ancient Gauls mentioned by classical writers. Part of the tremendous influence exercised by the *fili* was due to the belief in his powers of satire. The *fili* were held in such esteem that the annalists give the obituaries of the head-ollams as if they were so many princes. With the introduction of Christianity they seem to have gradually superseded the druid. We are here only concerned with the *fili* in his capacity of story-teller and poet. (1) The highest degree of *fili* is the *ollam* (ollave), who knows 350 stories; (2) the *ánruth*, 175 stories; (3) the *clíi*, 80 stories; (4) the *cana*, 60 stories; (5) the *doss*, 50 stories; (6) the *macfuirmid*, 40 stories; (7) the *fochlocon*, 30 stories; (8) the *drisac*, 20 stories; (9) the *taman*, 10 stories; (10) the *oblaire*, 7 stories. In LL. we are told that the stories (*scél*) are divided into primary and secondary, and that the latter are only obligatory on the first four of the grades enumerated. The higher grades were allowed a number of attendants, whom the kings had to support along with the poet himself. The 6th century monarch, Aed MacAinmirech, weary of the pretensions of the poets, attempted to banish them, which led to the famous assembly of Druim Ceta, where Columba intervened and reduced their number.

We have already stated that the stories which formed the stock-in-trade of the poets were divided into primary and secondary stories. Of the latter there were 100, but little is known of them. The oldest catalogue (contained in LL.) gives the titles of 187 of the primary tales arranged under the following heads—destructions, cow-spoils, courtships, battles, caves, navigations, violent deaths, expeditions, elopements and conflagrations; together with the following, which also reckon as prime-stories—irruptions, visions, loves, hostings and migrations. Of these stories 68 have been preserved in a more or less complete form. The tales enumerated in these catalogues in their substance doubtless go back to the 8th or even to the 7th century. It ought to be observed that the church never showed itself hostile to the *fili*, as it did to the druids. Dubthach, chief *fili* of Ireland in the time of St. Patrick, is represented as the saint's constant companion.

Like the official *fili*, the bards, an inferior class of poets, were divided into grades. There were both patrician and plebeian bards, each subdivided into eight degrees, having their own peculiar metres. In course of time the office of *fili* became extinct,

owing to a variety of causes, and from the 13th to the 16th century we find the hitherto despised family bard stepping into the place of the most influential literary man in Ireland. His importance was fully realized by the English Government, which did its best to suppress the order.

Mediaeval Romances.—The mediaeval romances form by far the most attractive part of Irish literature. Two main groups of stories have to be distinguished. The one is the Ulster cycle, with Conchobar and Cúchulinn as central figures. The other is the Southern or Leinster-Munster cycle, revolving round Finn and Ossian.

The Ulster cycle may be regarded as Ireland's most important contribution to the world's literature. The chief and at the same time the lengthiest romance in which the heroes of this group figure is the great epic, the *Táin Bó Cúalnge* or the Cattle-raid of Cooley (Co. Louth). Here we find ourselves in a world of barbaric splendour, and we are constantly reminded of the *Iliad*, though the Irish epic from a purely literary point of view cannot bear comparison with the work of Homer. The main actors in the drama are Conchobar, king of Ulster, the great warrior Cúchulinn (*q.v.*), Ailill and Medb, king and queen of Connaught, and Fergus, Conchobar's predecessor as king of Ulster, now in exile in Connaught. These persons may or may not have actually lived, but the Irish annalists and synchronists agree in placing them about the beginning of the Christian era. And there cannot be any doubt as to the antiquity of the state of civilization disclosed in this great saga. It has been repeatedly pointed out that the Irish heroes are equipped and conduct themselves in the same manner as the Gauls described by the Greek traveller Posidonius, and Prof. W. Ridgeway has shown that several articles of dress and armour correspond exactly to the La Tène types of the Continent. To mention a few primitive traits among many—the Irish champions of the *Táin* still fight in chariots, war-dogs are employed, whilst the heads of the slain are carried off in triumph and slung round the necks of the horses. It may also be mentioned that Emain Macha, Conchobar's residence, is reported by the annalists to have been destroyed in A.D. 323, and that portions of Meath, which is stated to have been made into a separate province in the 2nd century A.D., are in the *Táin* regarded as forming part of Ulster. Noteworthy is the exalted position occupied by the druid in the Ulster sagas, showing how little the romances were influenced by Christianity. No Roman soldier ever set foot in Ireland, and this early epic literature is of supreme value as a monument of primitive Celtic civilization. The YBL version of this epic preserves a number of forms as old as the O.Ir. glosses (*i.e.*, 8th century or earlier), and a curious story contained in LL. seems to point to the fact that the *Táin* was first committed to writing in the 7th century.

At this point it will be well to say a few words about the form of the *Táin*. The old Irish epic is invariably in prose with poems of varying length interspersed. The narrative and descriptive portions are in prose and are frequently followed by a brief epitome in verse. Dialogues, eulogies and laments also appear in metrical form. The oldest poems, termed rhetoric, which are best represented in LU., seem to be declamatory passages in rhythmical prose, not unlike the poetical passages in the Old Testament, and the original *Táin* may have consisted of such rhetorics bound together with short connecting pieces of prose. At a later date poems were inserted in the metres of the *filid*. The genesis of the *Táin* may thus be briefly summarized as follows. The story was first committed to writing in the 7th or 8th century, after which it was worked up by the *filid*. Extended versions existing in the 10th or 11th century form the basis of the copies we now possess.

Though the sagas of the Ulster cycle are eminently Irish and pagan in character and origin, it cannot be denied that traces of foreign influence are to be observed. A number of Latin and Norse loan-words occur in them, and there can be little doubt that the monkish scribes consciously thrust the supernatural element into the background.

From what we have already said it will be plain that the Irish epic is in a fluid state. The *Táin* is of interest in the history of literature as representing the preliminary stage through which

the great verse epics of other nations have had to pass, but its value as a work of art is limited by its form. As already stated, the atmosphere is frankly pagan and barbaric, with none of that courtly element which we find in the Arthurian epics. The two features which strike one most forcibly in the mediaeval Irish romances are dramatic force and humour. The unexpected and weird is always happening, the effect of which is considerably heightened by the grim nature of the actors. In particular the dialogues are remarkably brilliant and clever, and it is a matter for surprise that this gifted race never developed a drama of its own. This is doubtless partly due to the political conditions of the island. And, moreover, we are constantly struck by the lack of sustained effort which prevented the *filid* from producing great epics in verse. Dramatic material is abundantly present in the old epics, but it has never been utilized. Perhaps the most serious defect of most Irish literary products is the lack of any sense of proportion, which naturally goes hand in hand with the love of the grotesque.

The Ulster Cycle.—The *Táin Bó Cúalnge* formed a kind of nucleus round which a number of other tales clustered. A number of these are called *remscéla* or introductory stories to the *Táin*. Such are the "Revealing of the Táin," the "Debility of the Ultonians," "The Cattle-Driving of Regamon, Dartaid and Flidais," *Táin bó Regamna*, "The Cattle-Driving of Fraech," "The Dispute of the Swine-herds," telling the previous history of the Bulls, "The Capture of the Fairy Mound," "The Dream of Oengus," the "Adventures of Nera," the "Wooing of Ferb." Other stories form a kind of continuation of the *Táin*. Such are the "Battle of Rosnaree," the "Great Rout of the Plain of Murthemne" and "Cúchulinn's Death." We are also told of the vengeance taken on the slayers by Connall Cernach. Other stories deal with the "Conception of Conchobar," the "Conception of Cúchulinn," "The Glories of Conchobar's Reign," with an account of how he acquired the Throne from Fergus, "The Wooing of Emer and the Hero's Education in Scotland under Scathach," "The Siege of Howth," "Bricriu's Feast and the Exile of the Sons of Doel Dermait," "The Battle of the Boyne" (*Eriu*, vol. ii.), "The Deaths of Ailill, Medb and Connall Cernach," "Destruction of Bruden Dá Choca," "The Tragical Death of Conlaech at the hands of Cúchulinn his father," "The Deaths of Goll and Garbh," "The Sickbed of Cúchulinn," "The Intoxication of the Ultonians," "The Death of Conchobar," "The Phantom Chariot of Cúchulinn," in which the hero is brought up from the grave.

Four other stories in connection with the Ulster cycle remain to be mentioned. The first is *Scél mucci Maic Dathó* ("The Story of MacDathó's Pig"). In this savage but picturesque Irish story we find the Ulstermen vaunting their achievements against the Connaughtmen. Nowhere, perhaps, is the dramatic element better brought out. Apart from the *Táin* the greatest and at the same time the longest saga in which Cúchulinn figures is *Fled Bricrend* (Bricriu's Feast). Bricriu is the mischief-maker among the Ulstermen, and he in turn incites the three chief heroes, Cúchulinn, Connall Cernach and Loigaire Buadach, to claim the champion's portion in a feast which he prepared. In order to decide the dispute, visits are paid to Medb at Rath Cruachan and to Curói in Kerry, and the story ends with the "beheading incident," which occurs in the romance of "Sir Gawayne and the Green Knight."

But the story of the Ulster cycle which is better known than any other, is the story of the "Tragical Death of the Sons of Usnech, or the Life and Death of Deirdre," one of the "Three Sorrows of Story-telling." This is almost the only tale of the group which has survived in the minds of the common people down to the present day. It is foretold of Deirdre, a girl-child of great beauty, that she will be the cause of great misfortunes, but Conchobar, having lost his wife, determines to have her brought up in solitude and marry her himself. The oldest version of the story is found in LL., and the characters are as rugged and unsophisticated as those of the *Táin*. But in the later versions the savage features are toned down.

Few of the old romances deal directly with what we may call Irish mythology. The "Battle of Moytura" tells of the tre-

mendous struggle between the Tuatha Dé Danann and their enemies, the Fomorians. Connected with the events of this saga is the story of the "Tragic Deaths of the Sons of Tuirenn," which, though mentioned in Cormac's glossary, is not found in any ms. older than the 18th century. This is the second of the "Three Sorrows of Story-Telling." An old story dealing with Tuatha Dé Danann personages, but having a certain bearing on the Cúchulinn cycle, is the "Courtship of Etáin," who, though of supernatural (*sid*) birth, is wedded to a mortal king. Her former husband wins back Etáin from her mortal husband in a game of chess and carries her off to his fairy mound. For sake of completeness we may add the titles of two other well-known stories here. The one is the "Story of Baile the Sweet-Spoken." The other is the "Fate of the Children of Lir," the third of the "Three Sorrows of Story-telling," which is only known in a modern dress.

A large number of sagas, which claim to be founded on historical events, present a great similarity to the tales of the Ulster cycle. The "Destruction of Dind-Rig and Exile of Labraid Loingsach" relates how the kingdom of Leinster was snatched by one brother from another in the 6th century B.C. The story, of the visit of the pigmies to the court of Fergus MacLeite, king of Ulster in the 2nd century B.C., contained in a 15th-century ms., is commonly stated to have given Swift the idea of his *Gulliver's Travels to Lilliput*. *Cáithréim Chonghail Claringnigh*, which only occurs in a modernized 17th-century version, deals with a revolution in the province of Ulster, supposed to have taken place before the Christian era. The most important Old Irish saga after the *Táin* is beyond doubt the *Destruction of Dá Derga's Hostel*, contained in LU. It deals with events in the reign of the High-King Conaire Mór, who is said by the annalists to have been slain in 43 B.C. after a reign of 70 years.

We can do no more than enumerate the titles of other historical tales: The "Destruction of the Hostel of MacDareo," describing the insurrection of the Aithech-Tuatha (1st century A.D.), "The Expulsion of the Déisi" and the "Battle of Mag Lemna" (2nd century A.D.), "Battle of Mag Mucrimé" (A.D. 195 or A.D. 218), "Siege of Drom Damgaire" (3rd century), "Adventures of the Sons of Eochaid Muigmedóin, father of Niall Nóigiallach" (4th century), "Death of Crimthann" (reigned 366-378), "Death of Dathi" (d. 428), "Death of Murchertach, son of Erc," and "Death of Diarmait, son of Cerball" (6th century) "Wooing of Becfol, who became the wife of Diarmait, son of Aed Slane" (reigned 657-664), "Battle of Mag Rath" (637), "Battle of Carn Conaill" (c. 648), "Death of Maelfothartaig MacRomain" (7th century), who was a kind of Irish Hippolytus, "Battle of Allen" (722).

The visits of mortals to the Irish Elysium form the subject of three romances, and the whole question has been exhaustively dealt with by Kuno Meyer and Alfred Nutt in the *Voyage of Bran* (1895-97). Conla Caem, son of Conn Cétchathach, was one day seated by his father on the hill of Usnech, when he saw a lady in strange attire approaching invisible to all but himself. She describes herself as coming from the "land of the living," a place of eternal delight, and invites the prince to return with her. This is the *Imram* or Adventure of Conla Caem, the oldest text of which is found in LU. A similar story is entitled *Imram Brain maic Febail*, contained in YBL. and Rawlinson B 512 (the end also occurs in LU.). A later story preserved in BB., YBL. and the Book of Fermoy, tells of the visit of Cormac, grandson of Conn Cétchathach, to Tír Tairngiri. The romances we have just mentioned are almost entirely pagan in character, but a kindred class of story shows us how the old ideas were transformed under the influence of Christianity. A typical instance is *Imram curaig Maelduin*, contained in YBL. and in part in LU. *Imram ua Corra* (Book of Fermoy) and *Imram Suedgusa ocus Mac Riagla* (YBL.) resemble this, but in these cases, the voyage is undertaken as an expiation for crime. In the 11th century an unknown monkish writer compiled the *Navigatio S. Brendani*, drawing the material for his episodes from *Imram curaig Maelduin*.

Fenian or Ossianic Cycle.—Unfortunately the origin of the

stories and poems connected with Finn and his warriors is obscure, and scholars are by no means agreed over the question (see FINN MAC CUMHAIL). In the earlier, the Ultonian, cycle the figures and the age in which they live are sharply drawn, and we can have no hesitation in assuming that the *Táin* represents in the main the state of Ireland at the beginning of the Christian era. Finn and his companions are more nebulous personages, and, although it is difficult to discover the actual starting-point of the legend, yet from the 12th century onwards we are able to trace the development of the saga with some degree of certainty. Of the 134 pages contained in LU. only half-a-dozen deal with Finn as against 58 with Cúchulinn. Again in Urard MacCoisi's list of tales, which seems to go back to the 10th century, only two appear to deal with subjects taken from the Ossianic cycle. The vehicle of the older epic is prose, but this later cycle is clothed in ballad form. Of these ballads about a dozen, apart from poems in the *Dindsenchus* are preserved in LU., LL. and YBL., and none of these poems is probably much older than the 11th century. At the same time we do find a few prose tales, e.g., "*Fotha catha Cnucha*" in LU., describing the death of Cumall, Finn's father, and in LL. and Rawlinson B 502, part of which Zimmer assigns to the 7th century, we have the first story in which Finn actually occurs. But it is remarkable that in no case do tales belonging to the Finn cycle contain any of the old "rhetorics" which occur in the oldest of the Ulster romances. By the 12th century the stories of the Fiann and their destruction at the battle of Gabra must have been fully developed, and from this time onward they appear gradually to have supplanted the Cúchulinn cycle in popular favour.

We have already stated that the form assumed by the stories connected with Finn in the earliest mss. is that of the ballad, and this continued down to the 18th century. But here again the Irish poets showed themselves incapable of rising from the ballad to the true epic in verse. The oldest composition of any length which deals with the Ossianic legends is the *Acallam na Senórach* or Colloquy of the Old Men, which is mainly preserved in three 15th-century mss., the Book of Lismore, Laud 610 and Rawlinson 487. In this text we have the framework common to so much of the later Ossianic literature. Ossian and Cálte are represented as surviving the battle of Gabra and as living on until the time of Patrick. The inflated style to which the Irishman is so prone is seen at its worst in the 16th century *Battle of Ventry*, and we are treated to a nauseous heaping up of epithet upon epithet, e.g., we sometimes find as many as 27 adjectives accompanying a substantive running in alliterating sets of three.

Of greater literary interest are the later ballads connected with Finn and Ossian. Nutt has pointed out that there is a striking difference in spirit between the *Acallam na Senórach* and the 15th-16th century poems. In the latter Ossian is represented as a "pagan, defiant and reckless, full of contempt and scorn for the howling clerics and their churlish low-bred deity," whilst Patrick is a sour and stupid fanatic, harping with wearisome monotony on the damnation of Finn and all his comrades. The earliest collection of these later Ossianic poems is that made in Scotland by James Macgregor, dean of Lismore, early in the 16th century. Two other published collections are the first half of *Duanaire Finn* and the *Transactions of the Ossianic Society* (1854-61). We further possess a number of prose romances, which in their present form date from the 16th to the 18th century; e.g., *The Pursuit of Diarmaid and Gráinne*, *Finn and Gráinne*, *Death of Finn*, *The Clown in the Drab Coat*, *Pursuit of the Gilla Decair*, *The Enchanted Fort of the Quicken-tree*, *The Enchanted Cave of Ceis Corann*, *The Feast in the House of Conan*.

At the present moment it is impossible to give a complete survey of the other branches of mediaeval Irish literature. The attention of scholars has been largely devoted to the publication of the sagas to the neglect of other portions of the wide field. An excellent survey of the subject is given by K. Meyer, *Die Kultur der Gegenwart*, i. xi. 1, pp. 78-95 (Berlin-Leipzig, 1909).

As early as the Old Irish period nameless Irish poets were singing the praises of nature in a strain which sounds to our ears peculiarly modern, but it is, generally speaking, quite an accident

if any of the delightful little lyrics entered in the margins or on blank spaces in the mss. have remained. There are exquisite nature poems ascribed to Finn, which have been collected into a pamphlet with English renderings by Kuno Meyer (under the title of "Four Old Irish Songs of Summer and Winter," 1903), and he has edited a native poem referred to the 10th century in the form of a colloquy between Guaire of Aidne and his brother Marban. Another text full of passionate emotion and tender regret ascribed to the 9th century tells of the parting of a young poet and poetess, who after plighting their troth are separated for ever (*Liadain and Curithir*, ed. with trans. by K. Meyer, 1902). In the *Old Woman of Beare* (publ. K. Meyer, in *Otia Merseiana*) an old courtesan laments her departed youth, comparing her life to the ebbing of the tide (10th century).

Professional Literature.—We must now step aside from pure literature and turn our attention to the various productions of the professional learned classes of Ireland during the middle ages. The range of subjects coming under this heading is a very wide one, comprising history, genealogies, hagiology, topography, grammar, lexicography and metre, law and medicine. Irish tradition preserves the names of a number of antiquarian poets of pre-historic or early mediaeval times, such as Amergin, one of the Milesian band of invaders; Moran Roigne, Adna and his successor Ferceirtne, Torna (c. 400), Dallán Forgaill, Senchán Torpéist, and Cennfaelad (d. 678), but the poems attributed to these writers are of much later date. To Maelmura (d. 887) is attributed a poem on the Milesian migrations. Flanagan, son of Cellach, wrote a long composition on the deaths of the kings of Ireland, and Flann MacLonáin (d. 918), called by the Four Masters the Virgil of Ireland, wrote poems, of which about 1,000 lines survive. Cormacan, son of Maelbridge (d. 946), composed a vigorous poem on the circuit of Ireland. A poet whose poems are most valuable from an antiquarian point of view is Cinaed Ua h-Artacáin (d. 975). Contemporary with him is Eochaid O'Flainn (d. c. 1003). A little later comes MacLiach (d. 1016), who celebrated in verse the glories of the reign of Brian Boroime. Contemporary with MacLiach is Urard MacCoisi (d. 1023). To Cúán ua Lothcháin (d. 1024), chief poet in the reign of Mael-sheachlainn II., are ascribed poems on the antiquities of Tara. A writer who enjoyed a tremendous reputation in mediaeval Ireland was Flann Mainstrech (d. 1056), who in spite of his being a layman was head of the monastery school at Monasterboice. Flann's successor, Gilla Coemgin (d. 1072), gives us a chronological poem dealing with the annals of the world down to A.D. 1014. He also is the author of the Irish version of Nennius which contains substantial additions dealing with early Ireland. Minor writers of the same nature, some of whose works have come down to us, are Colmán O'Sesnáin (d. 1050), Néide ua Maelchonaire (d. 1136), Gilla na noem ua Duinn (d. 1160), Gilla Modua O'Casidy (1143). In the 13th century these historical poems become very rare. In the next century we again find antiquarian poets of whom the best-known is John O'Dugan (d. 1372), whose work was completed by his younger contemporary Gilla na naem O'Huidhrin. From the beginning of the 13th century the official poets began to give way to the hereditary bards and families of scribes. Among the chief bardic families we may mention the O'Dalys, the MacWards, the O'Higinns, the MacBrody's and the MacDaires, and in Scotland the MacVarrichs descendants of O'Daly (c. 1214-40). Gilla Brigde MacConmidhe was a contemporary of the last-mentioned bard. Donnchad Mór O'Dálaig is said to be the greatest religious poet that Ireland has produced. Angus O'Daly, who lived in the second half of the 16th century, was believed to have been employed by the English to satirize the chief Gaelic families in Ireland. Two members of the O'Higinn family deserve mention, Tadg mór O'Higinn (d. 1315) and Tadg Óg O'Higinn (d. 1448). A *duanaire* was inserted into YBL, which contains a large number of poems by him.

Closely connected with the compositions of the official poets are the works of native topography. The *Dindsenchus* is a compilation of etymologies of place names. But its chief value consists in the amount of legendary matter it contains, adduced in support of the etymologies given. A kindred compilation is the

Cóir Anmann (Fitness of Names), which does for personal names what the *Dindsenchus* does for geographical names.

History.—No people on the face of the globe have ever been more keenly interested in the past of their native country than the Irish. We may now describe briefly the historical works in prose which have come down to us. They may be divided into two classes, (1) works containing a connected narrative, (2) annals. Closely allied to these are the sagas dealing with the high-kings. The earliest of these histories is the wars of the Gael and Gall (*Cogad Gaedel re Gallaib*), which gives an account of the Viking invasions of Ireland, the career of Brian Boroime and the overthrow of the Norsemen at the battle of Clontarf, obviously written by an eye-witness of the battle, or from materials supplied by a person actually present. *Cathreim Cellacháin Caisil* treats of the conflicts between the Vikings and the Irish, and the *Leabhar Oiris* gives an account of Irish history from 979 to 1027. Another ancient work also partly preserved in LL. is the Book of Invasions (*Leabhar Gabhála*). This deals with the five pre-historic invasions of Ireland (see IRELAND: *Early History*) and the legendary history of the Milesians. Part 1 of O'Clery's recension was edited by Macalister and MacNeill (Dublin, n.d.). The *Boroma* or History of the Leinster Tribute contained in LL. belongs rather to romance. Another history is the *Triumphs of Turlough O'Brian*, written about the year 1459 by John MacCraith, a Munster historian. This inflated composition is an important source of information on Munster history from the landing of the Normans to the middle of the 14th century. A life of Hugh Roe O'Donnell, by Lughaidh O'Clery, and also a contemporary history of the *Flight of the Earls*, by Tadhg O'Cianan, have been published. See also *Leabhar chlainne Suábhne* (Walsh, 1920) and *mcGuádir Fhearmanach* (Dinneen, 1917). But the most celebrated Irish historian is certainly Geoffrey Keating (c. 1570-1646), who is at the same time the greatest master of Irish prose. He travelled up and down Ireland examining all the ancient records, and compiled a history of Ireland down to the Norman Conquest. Its value for the scholar lies in the fact that the author had access to many important sources of information now lost, and has preserved accounts of events independent of and differing from those contained in the Four Masters. In addition to the history and a number of poems, Keating is also the author of two theological works in Irish which are models of Irish prose.

From the writers of historical narrative we turn to the annalists, the most important sources of information with regard to Irish history. We may here mention the *Synchronisms* of Flann Mainstrech. Apart from this work the earliest collection of annals which has come down to us is the compilation by Tigernach O'Braein (d. 1088), abbot of Clonmacnoise. Tigernach, whose work is partly in Latin, partly in Irish, states that all Irish history previous to 305 B.C. is uncertain. The *Annals of Innisfallen* were perhaps compiled about 1215. The invaluable *Annals of Ulster* were compiled on Belle Isle on Upper Lough Erne by Cathal Maguire (d. 1498), and afterwards continued by two different writers down to 1604. The *Annals of Loch Cé* (near Boyle in Roscommon) were copied in 1588 and deal with Irish events from 1014 to 1636. The *Annals of Connaught* run from 1224 to 1562. The *Chronicon Scotorum* deals with Irish affairs down to 1135. The *Annals of Boyle* extend down to 1253. The *Annals of Clonmacnoise*, which come down to 1408, only exist in an English translation made by Connell MacGeoghegan in 1627. The most important of all these collections is the *Annals of the Four Masters* (so christened by Colgan), compiled in the Franciscan monastery of Donegal by Michael, Conary and Cucogry O'Clery and Ferfesa O'Mulconry. Michael O'Clery (1575-1643), the greatest of the four, was a lay brother in the order of St. Francis, and devoted his whole life to the history of Ireland. He collected all the historical mss. he could find, and was encouraged in his undertaking by Fergal O'Gara, prince of Coolavin, who paid all expenses. The great work, which was begun in 1632 and finished in 1636, comes down to 1616. Nearly all the materials from which O'Clery drew his statements are now lost. Very important, are the lists of genealogies which occupy a great deal of

space in the older mss. But by far the most important collection of all is that made by the last great shanachie Duaid MacFirbis, compiled between 1650 and 1666 in the college of St. Nicholas at Galway.

Religious Literature.—When we turn from secular to religious themes we find that Ireland is also possessed of a very extensive Christian literature, which is extremely valuable for the comparative study of mediaeval literature. One of the most important documents is the Tripartite Life of St. Patrick. The *Leabhar Breac* contains a quantity of religious tracts, most of which have been published. R. Atkinson issued a number of them under the title of *Passions and Homilies from Leabhar Breac* (1887). They do not however deal with the lives of any Irish saints. Stokes has published nine lives of Irish saints from the Book of Lismore. These lives also occur in the *Leabhar Breac*. Other lives of saints have been published by O'Grady in *Silva Gadelica*. Plummer published 17 lives in Irish and a volume of Latin lives. The longest life of St. Columba was compiled in 1536 at the command and with the help of Manus O'Donnell (O. Kelleher and Schöpperle, Chicago, 1918).

But the most interesting Irish religious text is the *Vision of Adamnan* (preserved in LU.), which Stokes assigns to the 11th century. The soul of Adamnan is represented as leaving his body for a space to visit heaven and hell under the conduct of an angel. The whole treatment of the theme challenges comparison with Dante's great poem, but the Irish composition contains many ideas peculiar to the land of its origin. Later specimens of this kind of literature tend to develop into grotesque buffoonery. We may mention the *Vision of Fursae*, the *Vision of Tundale* (Tnugdál), published by V. Friedel and K. Meyer (Paris, 1907), Laisrén's *Vision of Hell* and the *Vision of Merlino*. Kuno Meyer edited a tract on the Psalter in his *Hibernica Minora* from a 15th century Oxford ms., but he holds that the text goes back to 750. For the religious literature in general the reader may refer to O'Curry, *Lectures on the MS. Materials of Ancient Irish History* (pp. 339-434), and G. Dottin, "Notes bibliographiques sur l'ancienne littérature chrétienne de l'Irlande," in *Revue d'histoire et littérature religieuses*, v. 162-167. See also *Revue celtique*, xi. 391-404; *ib.* xv. 79-91.

An extraordinary production is *Aisling Meic Conglinne*, the Vision of Mac Conglinne, found in LB. and ascribed to the 12th century (ed. K. Meyer, 1892). The composition seems to be intended as a satire on the monks, and in particular as a travesty of mediaeval hagiology. Another famous satire, entitled "The Proceedings of the Great Bardic Institution," holds up the professional bards and their extortionate methods to ridicule (see *Transactions of the Ossianic Society*, vol. v.).

Collections of pithy sayings in the form of proverbs and maxims must have been made at a very early period. Not the least remarkable are the so-called Triads, 9th century (publ. K. Meyer, 1906), which illustrate every statement with three examples. There are also two documents attributed to 1st-century personages, "The Testament of Morann MacMóin to his son Feradach," which is quoted as early as the 8th century, and "The Instructions of Cúchulinn to his foster-son Lugaid." K. Meyer has published *Tecosca Cormaic* or the Precepts of Cormac MacAirt to his son Cairpre (1909), and R. M. Smith the *Senbriathra Zithaic* (1928).

Classical Stories.—With that enthusiasm for the classics which is characteristic of the Irish, it is not strange that we should find mediaeval versions of some of the better-known authors of antiquity. It is interesting to note that only those works are translated that could be utilized by the professional story-teller. So much so, that in the 10th century catalogue of sagas enumerated by Urdar MacCoisi we find mention of *Togail Troi* and *Scéla Alexandair maic Pilip*. An Irish abstract of the *Odyssey*, following an unknown source, and part of the story of Theseus have been published by K. Meyer. *Imthechta Aeniusa*, taken from the *Aeneid*, is contained in BB. and published by Calder (1903). A number of mss. contain the *Cath Catharda*, a version of books vi. and vii. (?) of Lucan's *Pharsalia*, which has been published by W. Stokes. There is further at least one ms. containing a version of Statius's *Thebaid* and of Heliodorus's *Aethi-*

opica. Somewhat later we have Irish versions, amongst others of the *Gesta Romanorum*, the *Historia Brittonum*, the Wars of Charlemagne (Hyde, 1917), the History of the Lombards, Sir John Maundeville's Travels (trans. by Fingin O'Mahony in 1475), the Book of Ser Marco Polo (abridged). Guy Earl of Warwick, Bevis of Southampton, the Quest of the Holy Grail, Octavian, the chronicle of Turpin, Balaam and Josaphat, and the story of Fierabras. For translation literature see M. Nettelau, *Revue celtique*, x. pp. 184, 460-461.

By the beginning of the Middle Irish period a good part of the cumbrous Old Irish verb-system had become obsolete, and texts which were at all faithfully copied had to be plentifully supplied with glosses. But even before this Cormac mac Cuillennáin, the bishop-king of Cashel (d. 903), had compiled a glossary of archaic words containing much invaluable information. Later collections of archaic words are O'Mulconry's Glossary (13th century), the Lecan Glossary (15th century), which draws principally from the glosses in the *Liber Hymnorum*, O'Davoren's Glossary (16th century), drawn principally from the Brehon Laws, a 16th century list of Latin and Irish names of plants employed in medicine, and O'Clery's Glossary (published at Louvain, 1643). BB. contains a curious tract on Ogamic writing. An Irish treatise on grammar, called *Uraicept na n-éces*, the Poet's Primer, traditionally ascribed to Cenníaelad and others, is contained in BB. and YBL. (Calder, 1917). The St. Gall glosses on Priscian contain Irish terms for all the nomenclature of the Latin grammarians, and show how extensive was the use made of Irish even in this department of learning.

Thurneysen has edited from BB., Laud 610 and TCD. ms. three treatises on metric which give an account of the countless metres practised by the *filid*. We have seen that there is some reason for believing that the primitive form of Irish verse was a kind of rhythmical alliterative prose as contained in the oldest versions of the sagas. The *filid* early became acquainted with the metres of the Latin church hymns, whence rhyme was introduced into Ireland. (This is the view of Thurneysen and Windisch. Others like Zeuss have maintained that rhyme was an invention of the Irish.) In any case the *filid* evolved an intricate system of rhymes for which it is difficult to find a parallel. The result of the complicated technique evolved in Ireland was an inclination to sacrifice sense to musical harmony. See K. Meyer, *A Primer of Irish Metrics* (1909).

Law and Medicine.—We can conclude this survey of mediaeval Irish literature by mentioning briefly two departments of learning to which much attention was paid in Ireland. These are law and medicine. The so-called Brehon Laws (*q.v.*) are represented as having been codified and committed to writing in the time of St. Patrick. The Brehon Laws were no doubt originally transmitted from teacher to pupil in the form of verse, and traces of this are to be found in the texts which have been preserved. But the Laws as we have them do not go back to the 5th century. Kuno Meyer has pointed out that in the commentary to one text, *Crith Gablach*, there are linguistic forms which must go back to the 8th century, and Arbois de Jubainville, who apart from Sir Henry Maine is the only scholar who has dealt with the subject, has attempted to prove from internal evidence that part of the oldest tract, the one on *Athgabáil* or Seizure, cannot, in its present form, be later than the close of the 6th century. Kuno Meyer has published the *Cáin Adamnáin* or Adamnan's Law from an Oxford ms. Adamnan succeeded in getting a law passed which forbade women to go into battle. An interesting text in prose and verse called *Leabhar na gCeart* or Book of Rights was edited with an English translation by O'Donovan (1847).

The medical profession in Ireland was hereditary in a number of families, such as the O'Lees (from Irish *liaig*, "a leech"), the O'Hickeys (Irish *icide*, "the healer"), the O'Shiels, the O'Casidys, and many others. These families each had their own special leech-books, some of which are still preserved. The medical literature which has come down to us is contained in mss. ranging from the 13th to the 18th centuries. The Irish mss. are translations from the Latin with the invariable commentary, and they further contain additions derived from experience. YBL. contains

four of these tracts, and amongst others we may mention the Book of the O'Hickeys, a translation of the *Lilium Medicinæ* of Bernard Gordon (written 1303), the Book of the O'Lees (written in 1443), the Book of the O'Shiels, transcribed in 1657, and the Book of MacAnlega, transcribed in 1512. Of these texts two have been published from mss. in Edinburgh and one from a ms. in R.I.A. Some few mss. deal with the subject of astronomy, one of which was published by Miss Power (1916).

LATER IRISH LITERATURE

With the steady advance of English culture on the heels of the English power after 1600 it was only natural that the school of bardic poets should decline. Amongst the prominent poets of this later period may be mentioned Tadhg Dall O'Higinn (d. shortly before 1617), published by Miss Knott (1922 and 1926), and Eochaidh O'Hussey, who between them have left behind nearly 7,000 lines in the classical metres, Bonaventura O'Hussey and Ferfesa O'Cainti. The intricate classical measures gradually broke down. Dr. Douglas Hyde gives it as his opinion that the exceedingly numerous metres known in Middle Irish had become restricted to a couple of dozen, and these nearly all heptasyllabic. However, during the 17th century we find a new school arising with new principles and new methods. These consisted in (1) the adoption of vowel rhyme in place of consonantal rhyme, (2) the adoption of a certain number of accents in each line in place of a certain number of syllables. (For English imitations see Hyde, *A Literary History of Ireland*, pp. 548 ff.)

The consequences of the changed political conditions were of the greatest importance. The bards, having lost their patrons in the general upheaval, threw behind them the old classical metres and turned to the general public. It is only during the last 25 years that the works of any of the poets of the 17th and 18th centuries have been published. Pierce Ferriter was the last chieftain who held out against Cromwell's army, and he was hanged in 1653. His poems have been edited by P. S. Dinneen (1903). The bard of the Williamite wars was David O'Bruadar (d. 1697-98), published by MacErlean (3 vols., 1910-17). From this period date three powerful satires on the state of affairs in Munster, and in particular on the Cromwellian settlers. Their titles are the Parliament of Clan Thomas, the Adventures of Clan Thomas, and the Adventures of Tadhg Dubh (by Egan O'Rahilly). A description of the parliament of Clan Thomas is given by Stern in the *Zeitschr. f. celt. Phil.* v. pp. 541 ff.

A little later we come across a band of Jacobite poets, whose pet theme was the *Aisling* or Vision, and we find several noteworthy war-songs. We can do no more than mention the names of John O'Neaghtan (d. c. 1720; edition of his poems by A. O'Farrelly, 1908), Egan O'Rahilly, who flourished between 1700 and 1726 (published by Irish Texts Society), Tadhg O'Naghten, Hugh MacCurtin, author of a grammar and part editor of O'Begley's *Dictionary*, John Clárach MacDonnell (1691-1754), John O'Tuomy (d. 1775), Andrew Magrath, Tadhg Gaolach O'Sullivan (d. c. 1795), author of a well-known and often published volume of religious poems, and Owen Roe O'Sullivan (d. 1784), the cleverest of the Jacobite poets (his verses and *bons mots* are still well known in Munster). These poets hailed mostly from the south, and it is chiefly the works of the Munster poets that have been preserved. Ulster and Connaught also produced a number of writers. The best known are Seumas Mac Cuarta (O'Muireadhaigh, Dundalk, 1925), Art MacCooey (O'Muirgheasa, Dundalk, 1913) and the Connaught poet Raftery (1784-1835), whose compositions have been rescued by Hyde (*Abhráin an Reachtúire*, 1903). Torlough O'Carolan (1670-1738), "the last of the bards," was really a musician. Having become blind he was educated as a harper and won great fame. Michael Comyn (b. c. 1688) is well known as the author of a version based upon older matter of "Ossian in the Land of Youth." This appears to be the only bit of deliberate creation in the later Ossianic literature. Brian Mac-Giolla Meidhre or Merriman (d. 1808) is the author of perhaps the cleverest sustained poem in the Irish language. His work, which is entitled the *Midnight Court*, was written in 1781 and contains about 1,000 lines with four rhymes in each line. Donough

MacConmara (Macnamara) (d. c. 1814) is best known as the author of a famous lyric "The Fair Hills of Holy Ireland," but he also wrote a mock epic describing his voyage to America and how the ship was chased by a French cruiser.

The translation of the New Testament made by William O'Donnell and published in 1603 was first undertaken in the reign of Queen Elizabeth, who sent over to Dublin the first fount of Irish type. It is perhaps of interest to note that the earliest specimen of printing in Irish is a poem on Doomsday (1571).

The scholars of the various Irish colleges on the Continent were particularly active in the production of books of devotion, many of them translated from Latin. We can mention only a few of the more important. *Sgathán an chrábhaidh* (*The Mirror of the Pious*), published in 1626 by Florence Conry; *Sgathán sacramente na h-Aithrighe* (*Mirror of the Sacrament of Penance*), by Hugh MacCathmhaoil, published at Louvain, 1618; *The Book of Christian Doctrine*, by Theobald Stapleton (Brussels, 1639); *Párrthas an Auma, or The Paradise of the Soul*, by Anthony Gernon (Louvain, 1645); a book on *Miracles*, by Richard MacGilla Cody (1667); *Lochrán na gcreidmheach, or Lucerna Fidelium*, by Francis O'Mulloy (Louvain, 1676); O'Donlevy's *Catechism* (Paris, 1742). O'Gallagher, bishop of Raphoe, published a collection of sermons which went through 20 editions and are still known at the present day. It is only within recent years that attention has been paid to the collection of folk-songs and tales in Irish. The first collection of the sort was Hyde's *Leabhar Sgeulúigheacta* (1889). We may mention among others Patrick O'Leary's *Sgeulúidheacht Chuige Mumhan* (1895); Hyde's *Beside the Fire* (1890) and *An Sgeulúidhe Gaedhealach*, 35 tales in Irish and French, reprinted from the *Annales de Bretagne* (1901); Daniel O'Fogharta's *Siamsa an Gheimhridh* (1892); J. Lloyd's *Sgéalaíde Oirghiall* (1905), his *Measgán Múscrae*, his *Cruach Conaill* and *Tonn Tóime*, Michael Timony's *Sgealta Gearra* (1906), and Larminie's *West Irish Folk-Tales* (1893). The most important collections of folk-songs are *Love-Songs of Connaught* (1893) and *Religious Songs of Connaught* (2 vols., 1906), both published by Hyde. An extensive collection of proverbs is the one entitled *Seanfhocla Uladh* by Henry Morris (1907). See also a large collection by O. Sióchfradha (1927), Hydes' *An Scath-run*, O'Rahilly's *Miscellany of Irish Proverbs* (1922) and O'Donoghue's *Munster Proverbs* (1902). It should be mentioned that the Saor-Stát is encouraging and paying for new contributions to Irish literature. About a score of books, chiefly stories and novels have been published in 1927 and 1928. Plays are being produced in Irish.

BIBLIOGRAPHY.—In the absence of a comprehensive history, the best manual is Eleanor Hull, *Text Book of Irish Literature* (2 parts, 1904-08; vol. 2 contains a bibliographical appendix). D. Hyde's larger *History of Irish Literature* (1899) is valuable for the more modern period. A full bibliography of all published material is contained in G. Dottin's article "La littérature gaélique de l'Irlande" (*Revue de synthèse historique*, vol. iii., p. 1 ff.). Dottin's article has been translated into English and supplemented by Joseph Dunn under the title of *The Gaelic Literature of Ireland* (Washington, 1906, privately printed). The following are important works:—W. Stokes and J. Strachan, *Thesaurus Palaeohibernicus* (2 vols., 1901-03); J. H. Bernard and R. Atkinson, *Liber Hymnorum* (1895); E. O'Curry, *Lectures on the ms. Materials of Ancient Irish History* (1873) and *Lectures on the Manners and Customs of the Ancient Irish* (3 vols., 1873); P. W. Joyce, *A Social History of Ancient Ireland* (2 vols., 1903); E. O'Reilly, *Irish Writers* (1820); S. H. O'Grady, *Catalogue of Irish mss. in the British Museum* (1901; Robin Flower completed this catalogue in 1926); H. d'Arbois de Jubainville, *Introduction à l'étude de la littérature celtique* (1883), *Essai d'un catalogue de la littérature épique de l'Irlande* (1883), *L'Épopée celtique en Irlande* (1892), *La Civilisation des Celtes et celle de l'épopée homérique* (1899); E. Windisch, *Táin Bó Cúalnge*, ed. with an introd. and German trans. (Leipzig, 1905); L. Winifred Faraday, *The Cattle-Raid of Cúalnge* (1904); the Irish text according to LU. and YBL. has been published as a supplement to *Eriu*; Eleanor Hull, *The Cuchulinn-saga* (1899); W. Ridgeway, "The Date of the First Shaping of the Cuchulinn Cycle," *Proceedings of the British Academy*, vol. ii. (1907); A. Nutt, *Cuchulinn, the Irish Achilles* (1899); H. Zimmer, "Keltische Beiträge" in *Zeitschrift f. deutsches Altertum*, vols. 32, 33 and 35, and "Über den compilerischen Charakter der irischen Sagentexte im sogenannten Lebor na hUidre," Kuhn's *Zeitschr.* xxviii. pp. 417-689. We cannot here enumerate the numerous heroic texts which have been edited. For texts published before 1883 see d'Arbois's

Catalogue, and the same writer gives a complete list in *Revue Celtique*, vol. xxiv, pp. 237 ff. The series of *Irish Texts*, vols. i–iv. (Leipzig, 1880–1901), by E. Windisch (vols. ii–iv. in conjunction with W. Stokes), contains a number of important texts. The Irish Texts Society has published 24 volumes of texts with translations. Others, more particularly these belonging to the Ossianic cycle, are to be found in S. H. O'Grady's *Silva Gadelica* (2 vols., 1902). See also R. Thurneysen, *Sagen aus dem alten Irland* (1901); P. W. Joyce, *Old Celtic Romances* (1901).

For the Ossianic cycle see H. Zimmer, "Keltische Beiträge III." in vol. 35 of the *Zeitschr. f. deutsches Altertum*, also *Göttinger Gelehrte Anzeigen*, 1887, pp. 153–199; A. Nutt, *Ossian and the Ossianic Literature* (1899); L. C. Stern, "Die ossianischen Heldenlieder," in *Zeitschr. f. vergleichende Literaturgeschichte* for 1895, trans. by J. L. Robertson in *Transactions of the Inverness Gaelic Society*, vol. xxii.; J. MacNeill, *Duanairé Finn* (1908); *Book of the Dean of Lismore*, ed. by T. MacLauchlan (1862), and in vol. i. of A. Cameron's *Reliquiae Celticae* (1892); *Transactions of the Ossianic Society* (6 vols., 1854–61); Miss Brooke, *Reliques of Ancient Irish Poetry* (1786).

Keating's *History* was translated by John O'Mahony (1866). The first part was edited with Eng. trans. by W. Halliday (1811) and the whole work in 3 vols. for the Irish Texts Society by D. Comyn and P. Dinneen (1901–08). For the work of the older bards see O'Rahilly's *Dánta gradha* (Dublin 1916 and Cork 1926) and his *Measgra Dánta* (1927); Father McKenna's *Dán Dé* (Dublin, n.d.); Bergin's contributions to *Studies*; McKenna's *Poems of Aongus O'Dálaigh*. Editions of the poems of Ferriter, Geoffrey O'Donoghue, O'Rahilly, John O'Tuomy, Andrew Magrath, John Claragh MacDonnell, Tadhg Gaolach and Owen Roe O'Sullivan by Dinneen, Gaelic League, Dublin, and Irish Texts Society, London, 1900–03; Loyd's *Duanairé na Midhe* (Dublin, 1914); O. Muirghéasa's *Cead de Cheoltaibh Vladh* (Dublin, 1915), etc. (E. C. Q.; D. Hy.)

IRISH MOSS or **CARRAGEEN** (Irish *carraigeen*, "moss of the rock"), a seaweed (*Chondrus crispus*) which grows abundantly along the rocky parts of the Atlantic coast of Europe and North America. In its fresh condition the plant is soft and cartilaginous, varying in colour from a greenish-yellow to a dark purple or purplish-brown; but when washed and sun-dried for preservation it has a yellowish translucent horn-like aspect and consistency. The principal constituent of Irish moss is a mucilaginous body, of which it contains about 55%; and with that it has nearly 10% of nitrogenous material and about 15% of mineral matter rich in iodine and sulphur. When softened in water it has a sea-like odour, and from the abundance of its mucilage it will form a jelly on boiling with from 20 to 30 times its weight of water. The jelly thus formed of Irish moss is used as food. It may also be used as a thickener in calico-printing and for fining beer.

IRKUTSK, a town in the Siberian Area of the R.S.F.S.R. in lat. 52° 36' N., long. 104° 10' E., altitude 1,490 ft. It is situated on the right bank of the Angara river, a tributary of the Yenisei river, 45 m. below its outflow from Lake Baikal; its suburb Glazkovskoe lies on the left bank, and a pontoon bridge spans the river, which is 630 yd. wide. The railway and station are on the left bank. The Irkut river, from which the town of Irkutsk takes its name, enters the Angara river on its left bank, but is not navigable and the small Ushakovka river flows through the town and enters the Angara on the right bank. The town grew out of the winter quarters established by Ivan Pokhabov in 1652 for the collection of the fur tax from the Buriats. Its advantageous position for trade with China, the Amur region, the Lena goldfields and the fur regions of Siberia have made it an important city; its population in 1926 was 98,979. A post road runs north to the Lena and Yakutsk and south-east to Listvenichnoe on Lake Baikal, and other roads link it with the east. The Angara is navigable for steamers to Lake Baikal, though the current is against them. The river is frozen from January to April. The average January temperature is –5.4° F, July 65.1° F; the average rainfall per annum is 14.5 in. The town is well built with wide streets and has a drainage system and an electric power station. In 1879 fire destroyed many of the public buildings, including the library and museum of the Russian Geographical Society which has here the headquarters of its Siberian section, with valuable books, maps and exhibits. The town has long been a cultural centre for the district. It contains schools, a training college for teachers and a recently established Workers' Scientific Institute. St. Innocent's monastery, five miles outside the town influenced much of Eastern Siberia. Its industries include brewing, timber-

milling, flour-milling, leather works, the making of fur and sheep-skin coats and various small articles especially for the posting routes. It was a storm centre from 1918 to 1921 and much damage was then done to the town and railway. The State gold treasure, which had been removed from Leningrad under the charge of employees of the tsarist régime, was handed over by them to the Bolsheviks in Irkutsk in 1920; and here Admiral Kolchak was executed in the same year. The town was in tsarist times the centre of the Irkutsk government, an area occupying 287,061 sq.m., but is now only the centre of one of the twenty counties of the Siberian Area (*q.v.*).

IRMIN or **IRMINUS**, in Teutonic mythology, a deified eponymic hero of the Herminones. The chief seat of his worship was Irminsal, or Ermensul, in Westphalia. Wooden pillars raised to his honour were regarded as sacred by the Saxons.

IRNERIUS, Italian jurist, sometimes referred to as "lucerna iuris." He taught the "free arts" at Bologna, his native city, during the earlier decades of the 12th century. Of his personal history little is known, except that he died, perhaps during the reign of the emperor Lothair II., but certainly before 1140. He was the first of the Glossators (*see* GLOSS), and according to ancient opinion (which, however, has been much controverted) was the author of the epitome of the *Novellae* of Justinian, called the *Authentica*, arranged according to the titles of the *Code*. (*See* ROMAN LAW.)

IRON, a metallic chemical element. Although iron (symbol Fe, atomic number 26, atomic weight 55.84, isotopes 56 and 54) occurs only sparingly in the free state, the abundance of ores from which it may be readily obtained led to its application in the arts at a very remote period. It is generally agreed, however, that the iron age, the period of civilization during which this metal played an all-important part, succeeded the ages of copper and bronze, notwithstanding the fact that the extraction of these metals required greater metallurgical skill. The Assyrians and Egyptians made considerable use of the metal; and in Gen. iv. 22 mention is made of Tubal-cain as the instructor of workers in iron and copper. The earlier sources of the ores appear to have been in India; but it was also obtained by the Greeks from the south coast of the Black sea, and by the Romans from Spain and Elba.

The chief occurrences of metallic iron are as minute spiculae disseminated through basaltic rocks, as at Giant's Causeway and in the Auvergne, and, more particularly, in meteorites (*q.v.*). In combination it occurs, usually in small quantity, in most natural waters, in plants and as a necessary constituent of blood. The economic sources are treated under IRON AND STEEL below; in the same place will be found accounts of the manufacture, properties and uses of the metal, the present article being confined to its chemistry. The principal iron ores are the oxides and carbonates, and these readily yield the metal by smelting with carbon. The metal so obtained invariably contains a certain amount of carbon, free or combined, and the proportion and condition regulate the properties of the metal, giving origin to the three important varieties: cast iron, steel, wrought iron. The perfectly pure metal may be prepared by heating the oxide or oxalate in a current of hydrogen: when obtained at a low temperature it is a black powder which oxidizes in air with incandescence; *i.e.*, it is "pyrophoric." It may be obtained electrolytically from solutions of ferrous salts.

Properties.—Iron has a silvery lustre and takes a high polish. Its specific gravity is 7.84; and the average specific heat over the range 15°–100° C is 0.10983; this value increases with temperature to 850°, and then begins to diminish. It is the most tenacious of all the ductile metals at ordinary temperatures with the exception of cobalt and nickel; it becomes brittle, however, at the temperature of liquid air. It softens at a red heat, and may be readily welded at a white heat; above this point it becomes brittle. Pure iron melts at c. 1525° C and may be distilled in the electric furnace. It is attracted by a magnet and may be magnetized, but the magnetization is quickly lost. The variation of physical properties which attends iron on heating has led to the view that the metal exists in allotropic forms. This has been proved

recently by X-ray analysis. (See IRON AND STEEL.)

When pure iron is cooled from its melting point, its temperature falls evenly to 1400° and then remains almost stationary for a time; the cooling again becomes regular when 890° is reached, where a similar lag occurs or even a rise of temperature (which may be so pronounced as to cause a flow or recalescence); with still further cooling, yet a third lag is found at 760°. Similar irregularities occur at nearly the same (but slightly higher) temperatures when iron is slowly heated. Moreover, at these temperatures other physical properties of the metal (such as the coefficient of expansion, electrical resistance, and especially the characteristic magnetic property) undergo sudden changes, which lead to the assumption that there are four allotropic modifications of iron with transition points thus:

The crystal structure of α , β and δ is the same, viz., body-centred cubic (see CRYSTALLOGRAPHY), but that of γ -iron is a face-centre cube, and this difference is held by some metallurgists to show that β -iron is not a distinct modification, but only a solid solution of α and γ -iron.

It should be pointed out that "pure" iron is almost a curiosity, for the metal, as commonly used, nearly always contains a certain small proportion of carbon which much modifies its properties.

Iron is very reactive chemically. Exposed to atmospheric influences it is more or less rapidly corroded, giving the familiar rust (*q.v.*). For the production of rust, the presence of water and oxygen does not seem to be sufficient, and an "impurity" seems to be essential; this is provided usually in the iron itself or by the presence of carbon dioxide. The decomposition of steam by passing it through a red-hot gun-barrel, resulting in the liberation of hydrogen and the production of magnetic iron oxide, Fe_3O_4 , is a familiar laboratory method for preparing hydrogen (*q.v.*). When strongly heated, iron inflames in oxygen and in sulphur vapour; it also combines directly with the halogens. It dissolves in most dilute acids with liberation of hydrogen, the reaction between sulphuric acid and iron-turnings being used for the commercial manufacture of this gas. It dissolves in dilute cold nitric acid with the formation of ferrous and ammonium nitrates, no gases being liberated; when heated, or with stronger acid, ferric nitrate is formed with evolution of nitrogen oxides.

After having been immersed in strong nitric acid, iron neither dissolves in acids nor precipitates metals from solutions. This "passivity" may be brought about by immersion in other solutions, especially by those containing such oxidizing anions as NO_3^- , ClO_3^- , less strongly by the anions SO_4^{2-} , CN^- , CNS^- , $\text{C}_2\text{H}_3\text{O}_2^-$, OH^- , while Cl^- , Br^- practically inhibit passivity; H^+ is the only cation which has any effect, and this tends to exclude passivity. It is also occasioned by anodic polarization of iron in sulphuric acid. Several hypotheses have been promoted to explain this behaviour, and, although the question is not definitely settled, the more probable view is that it is caused by the formation of a film of an oxide (see U. R. Evans, *Journ. Chem. Soc.*, 1927, p. 1020). Other metals also exhibit the phenomenon of passivity under similar conditions.

COMPOUNDS OF IRON

Oxides and Hydroxides.—Iron forms three oxides: ferrous oxide, FeO ; ferric oxide, Fe_2O_3 ; and ferrous-ferric oxide, Fe_3O_4 . The first two give rise to well-defined series of salts, the ferrous salts, wherein the metal is bivalent, and the ferric salts wherein the metal is trivalent; the former readily pass into the latter on oxidation, and the latter into the former on reduction.

Ferrous oxide is obtained as a black pyrophoric powder when ferric oxide is reduced in hydrogen at 300°. Sabatier and Senderens obtained it by acting with nitrous oxide on metallic iron at 200°, and Tissandier by heating the metal to 900° in carbon dioxide; Donau, on the other hand, obtained a magnetic and crystalline ferrous-ferric oxide at 1200°. It may also be prepared as a black velvety powder which readily takes up oxygen from the air by adding ferrous oxalate to boiling caustic potash. Ferrous hydrate, $\text{Fe}(\text{OH})_2$, when prepared from a pure ferrous salt and caustic soda or potash free from air, is a white powder which

may be preserved in an atmosphere of hydrogen. Usually, however, it forms a greenish mass, owing to partial oxidation. It oxidizes on exposure with considerable evolution of heat; it rapidly absorbs carbon dioxide, and readily dissolves in acids to form ferrous salts, which are usually white when anhydrous, but greenish when hydrated.

Ferric oxide or iron sesquioxide, Fe_2O_3 , constitutes the valuable ores red haematite and specular iron; the minerals brown haematite or limonite, and göthite and also iron rust are hydrated forms. It is obtained as a steel-grey crystalline powder by igniting any ferric salt containing a volatile acid or by passing ferric chloride vapour over heated lime. When finely ground it forms a brownish red powder which dissolves slowly in acids, the most effective solvent being a boiling mixture of eight parts of sulphuric acid and three of water. Ferric oxide is employed as a pigment, as jeweller's rouge and for polishing metals. Several ill-defined hydrates are known, corresponding to various minerals in composition, and "colloidal" solutions have also been prepared. (See COLLOIDS.) Thomas Graham obtained a soluble hydrate by dissolving the freshly prepared hydrate in ferric chloride and dialysing the solution, the soluble hydrate being left in the dialyser. All the chlorine, however, does not appear to be removed by this process, the residue having the composition $8\text{Fe}(\text{OH})_3 \cdot \text{FeCl}_3$; but it may be by electrolysis in a porous cell. On standing, the solution usually gelatinizes, a process accelerated by the addition of an electrolyte. It is employed in medicine under the name *Liquor ferri dialysati*, or "dialysed iron."

Red ferric hydroxide dissolves in acids to form a well-defined series of salts, the ferric salts, also obtained by oxidizing ferrous salts; they are usually colourless when anhydrous, but yellow or brown when hydrated. It has also feebly acidic properties, forming *ferrites* with strong bases.

Magnetite, Fe_3O_4 , is regarded as ferrous ferrite, $\text{FeO} \cdot \text{Fe}_2\text{O}_3$. Most "mill scale," i.e., the oxidized surface formed on red hot iron and steel, is Fe_3O_4 . This important ore of iron is most celebrated for its magnetic properties, but the mineral is not always magnetic, although invariably attracted by a magnet. It may be obtained artificially by passing steam over red-hot iron. It dissolves in acids to form a mixture of a ferrous and ferric salt, and if an alkali is added to the solution a black precipitate is obtained which dries to a dark brown mass of the composition $\text{Fe}(\text{OH})_2 \cdot \text{Fe}_2\text{O}_3$; this substance is attracted by a magnet, and thus may be separated from the admixed ferric oxide. Calcium, magnesium and zinc ferrites, $\text{RO} \cdot \text{Fe}_2\text{O}_3$ ($\text{R} = \text{Ca}, \text{Mg}, \text{Zn}$), are obtained by intensely heating mixtures of the oxides; magnesium ferrite occurs in nature as the mineral magnoferrite, and zinc ferrite as franklinite, both forming black octahedra.

Ferric Acid, H_2FeO_4 .—By fusing iron with saltpetre and extracting the melt with water, or by adding a solution of ferric nitrate in nitric acid to strong potash, an amethyst or purple-red solution is obtained which contains potassium ferrate. The same solution results when chlorine is passed into strong potash solution containing ferric hydrate in suspension. Haber and Pick prepared potassium ferrate by electrolysis concentrated potash solution at 70 degrees Centigrade, between two cast iron electrodes, the current being reversed every few minutes. When concentrated, the solution is nearly black, and on heating it yields a yellow solution of potassium ferrite, oxygen being evolved. Barium ferrate, $\text{BaFeO}_4 \cdot \text{H}_2\text{O}$, obtained as a dark red powder by adding barium chloride to a solution of potassium ferrate, is fairly stable. It dissolves in acetic acid to form a red solution, is not decomposed by cold sulphuric acid, but with hydrochloric or nitric acid it yields barium and ferric salts, with evolution of chlorine or oxygen.

Halogen Compounds.—Ferrous fluoride, FeF_2 , is obtained as colourless prisms (with $8\text{H}_2\text{O}$) by dissolving iron in hydrofluoric acid, or as anhydrous colourless rhombic prisms by heating iron or ferric chloride in dry hydrofluoric acid gas. Ferric fluoride, FeF_3 , is obtained as colourless crystals (with $4\frac{1}{2}\text{H}_2\text{O}$) by evaporating a solution of the hydroxide in hydrofluoric acid. When heated in air it yields ferric oxide. Ferrous chloride, FeCl_2 , is obtained as shining scales by passing hydrochloric acid gas over red-hot iron, or by reducing ferric chloride in a current of hy-

drogen. It is very deliquescent, and freely dissolves in water and alcohol. Heated in air it yields a mixture of ferric oxide and chloride, and in steam magnetic oxide, hydrochloric acid, and hydrogen. It absorbs ammonia gas, forming the compound $\text{FeCl}_2 \cdot 6\text{NH}_3$, which on heating loses ammonia, and, finally, yields ammonium chloride, nitrogen and iron nitride. It fuses at a red-heat, and volatilizes at a yellow-heat; its vapour density at $1300^\circ\text{--}1400^\circ$ corresponds to the formula FeCl_2 . By evaporating in vacuo the solution obtained by dissolving iron in hydrochloric acid, there result bluish monoclinic crystals of $\text{FeCl}_2 \cdot 4\text{H}_2\text{O}$, which deliquesce, turn greenish on exposure to air, and effloresce in a desiccator. By adding ammonium chloride to the solution, evaporating in vacuo and then volatilizing the ammonium chloride, anhydrous ferrous chloride is obtained. The solution, in common with those of most ferrous salts, absorbs nitric oxide with the formation of a brownish solution.

Ferric chloride, FeCl_3 , may be obtained anhydrous by the action of dry chlorine on the metal at a moderate red-heat, or by passing hydrochloric acid gas over heated ferric oxide. It forms iron-black plates or tablets which appear red by transmitted and a metallic green by reflected light. It is very deliquescent, and readily dissolves in water, forming a brown or yellow solution, from which several hydrates may be separated. The solution is best prepared by dissolving the hydroxide in hydrochloric acid and removing the excess of acid by evaporation, or by passing chlorine into the solution obtained by dissolving the metal in hydrochloric acid and removing the excess of chlorine by a current of carbon dioxide. It also dissolves in alcohol and ether; boiling-point determinations of the molecular weight in these solutions point to the formula FeCl_3 . Vapour density determinations at 448° indicate a partial dissociation of the double molecule Fe_2Cl_6 ; on stronger heating it splits into ferrous chloride and chlorine. It forms red crystalline double salts with the chlorides of the metals of the alkalis and of the magnesium group. An aqueous solution of ferric chloride is used in pharmacy under the name *Liquor ferri perchloridi*.

Ferrous bromide, FeBr_2 , is obtained as yellowish crystals by the union of bromine and iron at a dull red-heat, or as bluish-green rhombic tables of the composition $\text{FeBr}_2 \cdot 6\text{H}_2\text{O}$ by crystallizing a solution of iron in hydrobromic acid. Ferric bromide, FeBr_3 , is obtained as dark red crystals by heating iron in an excess of bromine vapour. It closely resembles the chloride in being deliquescent, dissolving ferric hydrate and in yielding basic salts. Ferrous iodide, FeI_2 , is obtained as a grey crystalline mass by the direct union of its components. Ferric iodide does not appear to exist.

Sulphur Compounds.—Ferrous sulphide, FeS , results from the direct union of its elements, best by stirring molten sulphur with a white-hot iron rod, when the sulphide drops to the bottom of the crucible. It then forms a yellowish crystalline mass, which readily dissolves in acids with the liberation of sulphuretted hydrogen. Heated in air it at first partially oxidizes to ferrous sulphate, and at higher temperatures it yields sulphur dioxide and ferric oxide. It is unaltered by ignition in hydrogen. A black amorphous form results when ferrous salts are precipitated by ammonium sulphide.

Ferric-sulphide, Fe_2S_3 , is obtained by gently heating a mixture of its constituent elements, or by the action of sulphuretted hydrogen on ferric oxide at temperatures below 100° . It is also prepared by precipitating a ferric salt with ammonium sulphide; unless the alkali be in excess a mixture of ferrous sulphide and sulphur is obtained. Magnetic pyrites or pyrrhotite has a composition varying between $5\text{FeS} \cdot \text{Fe}_2\text{S}_3$ and $6\text{FeS} \cdot \text{Fe}_2\text{S}_3$. It has a somewhat brassy colour, and occurs massive or as hexagonal plates; it is attracted by a magnet and is sometimes itself magnetic. The mineral is abundant in Canada, where the presence of about 5% of nickel makes it a valuable ore of this metal. Iron disulphide, FeS_2 , constitutes the minerals pyrite, which is important as a source of sulphuric acid, and marcasite (q.v.); copper pyrites is $(\text{Cu}, \text{Fe})\text{S}_2$. Pyrite may be prepared artificially by gently heating ferrous sulphide with sulphur, or as brassy octahedra and cubes by slowly heating an intimate mixture of ferric

oxide, sulphur and sal-ammoniac. It is insoluble in dilute acids, but dissolves in nitric acid with separation of sulphur.

Ferrous sulphate, green vitriol or copperas, $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$, was known to, and used by, the alchemists; it is mentioned in the writings of Agricola, and its preparation from iron and sulphuric acid occurs in the *Tractatus chymico-philosophicus* ascribed to Basil Valentine. It occurs in nature as the mineral melanterite, either crystalline or fibrous, but usually massive; it appears to have been formed by the oxidation of pyrite or marcasite. It is manufactured by piling pyrites in heaps and exposing to atmospheric oxidation, the ferrous sulphate thus formed being dissolved in water, and the solution run into tanks, where any sulphuric acid which may be formed is decomposed by adding scrap iron. By evaporation the green vitriol is obtained as large crystals. Ferrous sulphate forms large green crystals belonging to the monoclinic system; rhombic crystals, isomorphous with zinc sulphate, are obtained by inoculating a solution with a crystal of zinc sulphate, and triclinic crystals of the formula $\text{FeSO}_4 \cdot 5\text{H}_2\text{O}$ by inoculating with copper sulphate. By evaporating a solution containing free sulphuric acid in a vacuum, the hepta-hydrated salt first separates, then the penta-, and then a tetra-hydrate, $\text{FeSO}_4 \cdot 4\text{H}_2\text{O}$, isomorphous with manganese sulphate. By gently heating in a vacuum to 140° , the hepta-hydrate loses 6 molecules of water, and yields a white powder, which on heating in the absence of air gives the anhydrous salt. The monohydrate also results as a white precipitate when concentrated sulphuric acid is added to a saturated solution of ferrous sulphate. Alcohol also throws down the salt from aqueous solution, the composition of the precipitate varying with the amount of salt and precipitant employed. The solution absorbs nitric oxide to form a dark brown solution, which loses the gas on heating or by placing in a vacuum. Ferrous sulphate forms double salts with the alkaline sulphates. The most important is ferrous ammonium sulphate, $\text{FeSO}_4 \cdot (\text{NH}_4)_2\text{SO}_4 \cdot 6\text{H}_2\text{O}$, obtained by dissolving equivalent amounts of the two salts in water and crystallizing. It is very stable and is much used in volumetric analysis. It is often called Mohr's salt.

Ferric sulphate, $\text{Fe}_2(\text{SO}_4)_3$, is obtained by adding nitric acid to a hot solution of ferrous sulphate containing sulphuric acid, colourless crystals being deposited on evaporating the solution. The anhydrous salt is obtained by heating these, or by adding strong sulphuric acid to a solution. It is sparingly soluble in water, and on heating it yields ferric oxide and sulphur dioxide. Many basic ferric sulphates are known, some of which occur as minerals. The iron alums are obtained by crystallizing solutions of equivalent quantities of ferric and an alkaline sulphate. Ferric potassium sulphate, common iron alum, $\text{K}_2\text{SO}_4 \cdot \text{Fe}_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$, forms bright violet octahedra.

Nitrides, Nitrates, etc.—Several nitrides are known. Guntz obtained ferrous nitride, Fe_3N_2 , and ferric nitride Fe_2N , as black powders by heating lithium nitride with ferrous potassium chloride and ferric potassium chloride respectively. Fowler obtained a nitride Fe_2N by acting upon anhydrous ferrous chloride or bromide, finely divided reduced iron, or iron amalgam with ammonia at 420° ; and also, in a compact form, by the action of ammonia on red-hot iron wire. It oxidizes on heating in air, and ignites in chlorine; on solution in mineral acids it yields ferrous and ammonium salts, hydrogen being liberated. A nitride appears to be formed when nitrogen is passed over heated iron, since the metal is rendered brittle. Ferrous nitrate, $\text{Fe}(\text{NO}_2)_2 \cdot 6\text{H}_2\text{O}$, is a very unstable salt, and is obtained by mixing solutions of ferrous sulphate and barium nitrate, filtering and crystallizing in a vacuum over sulphuric acid. Ferric nitrate, $\text{Fe}(\text{NO}_2)_3$, is obtained by dissolving iron in nitric acid (the cold dilute acid leads to the formation of ferrous and ammonium nitrates) and crystallizing, when cubes of $\text{Fe}(\text{NO}_2)_3 \cdot 6\text{H}_2\text{O}$ or monoclinic crystals of $\text{Fe}(\text{NO}_2)_3 \cdot 9\text{H}_2\text{O}$ are obtained. It is used as a mordant.

Ferrous solutions absorb nitric oxide, forming dark green to black solutions. The coloration is due to the production of unstable compounds of the ferrous salt and nitric oxide, probably of the type $2\text{FeSO}_4 \cdot \text{NO}$; the reaction, however, is reversible, the composition varying with temperature, concentration and nature of the salt. The reaction is utilized in the "brown ring" test for

nitrides. Reddish brown amorphous powders of the formulae $2\text{FeCl}_2\cdot\text{NO}$ and $4\text{FeCl}_2\cdot\text{NO}$ are obtained by passing the gas over anhydrous ferric chloride. By passing the gas into an ethereal solution of the salt, nitrosyl chloride is produced, and on evaporating over sulphuric acid, black needles of $\text{FeCl}_2\cdot\text{NO}\cdot 2\text{H}_2\text{O}$ are obtained, which at 60° form the yellow $\text{FeCl}_2\cdot\text{NO}$. Complicated compounds discovered by Roussin (*Ann. Chim. Phys.*, 1858, 52, p. 285) are obtained by the interaction of ferrous sulphate and alkaline nitrates and sulphides. Two classes may be distinguished:—(1) the ferrodinitroso salts; e.g., $\text{K}[\text{Fe}(\text{NO})_2\text{S}]$, potassium ferrodinitrososulphide, and (2) the ferroheptanitroso salts; e.g., $\text{K}[\text{Fe}_7(\text{NO})_7\text{S}_2]$, potassium ferroheptanitrososulphide. These salts yield the corresponding acids with sulphuric acid. For further information the above paper by Roussin, and also one by Pavel (*Ber.*, 1882, 15, p. 2600), should be consulted.

Phosphides, Phosphates.—H. Le Chatelier and S. Wologdine obtained Fe_3P , Fe_2P , FeP , Fe_2P_3 , but failed to prepare five other phosphides previously described. Fe_3P occurs as crystals in the product of fusing iron with phosphorus; it dissolves in strong hydrochloric acid. Fe_2P forms crystalline needles insoluble in acids except aqua regia; it is obtained by fusing copper phosphide with iron. FeP is obtained by passing phosphorus vapour over Fe_2P at a red-heat. Fe_2P_3 is prepared by the action of phosphorus iodide vapour on reduced iron. Ferrous phosphate occurs in nature as the mineral vivianite $\text{Fe}_3(\text{PO}_4)_2\cdot 8\text{H}_2\text{O}$. It may be obtained artificially as a white precipitate, which rapidly turns blue or green on exposure, by mixing solutions of ferrous sulphate and sodium phosphate. It is employed in medicine. Normal ferric phosphate, $\text{FePO}_4\cdot 2\text{H}_2\text{O}$, occurs as the mineral strengite, and is obtained as a yellowish-white precipitate by mixing solutions of ferric chloride and sodium phosphate. It is insoluble in dilute acetic acid, but dissolves in mineral acids. The acid salts $\text{Fe}(\text{H}_2\text{PO}_4)_3$ and $2\text{FeH}_2(\text{PO}_4)_2\cdot 5\text{H}_2\text{O}$ have been described. Basic salts have been prepared, and several occur in the mineral kingdom; dufrenite is $\text{Fe}_2(\text{OH})_2\text{PO}_4$.

Arsenides, Arsenites, etc.—Several iron arsenides occur as minerals; mispickel or arsenical pyrites, Fe_2AsS_2 , is an important commercial source of arsenic. A basic ferric arsenite, $4\text{Fe}_2\text{O}_3\cdot\text{As}_2\text{O}_3\cdot 5\text{H}_2\text{O}$, is obtained as a flocculent brown precipitate by adding an arsenite to ferric acetate, or by shaking freshly prepared ferric hydrate with a solution of arsenious oxide. The last reaction is the basis of the application of ferric hydrate as an antidote in arsenical poisoning. Normal ferric arsenate, $\text{FeAsO}_4\cdot 2\text{H}_2\text{O}$, constitutes the mineral scorodite. On the constitution of pharmacosiderite and acid arsenates, see N. H. Hartshorne, *Journ. Chem. Soc.*, 1927, p. 1759.

Carbides, Carbonates.—The carbide of iron Fe_3C plays an important part in determining the properties of the different modifications of the commercial metal, which are discussed under IRON AND STEEL.

Ferrous carbonate, FeCO_3 , or spathic iron ore, may be obtained as microscopic rhombohedra by adding sodium bicarbonate to ferrous sulphate and heating to 150° for 36 hours. Ferrous sulphate and sodium carbonate in the cold give a flocculent precipitate, at first white but rapidly turning green owing to oxidation. A soluble carbonate and a ferric salt give a precipitate which loses carbon dioxide on drying. Of great interest are the carbonyl compounds. Ferropentacarbonyl, $\text{Fe}(\text{CO})_5$, obtained by L. Mond, Quincke and Langer, by treating iron from ferrous oxalate with carbon monoxide, and heating at 150° , is a pale yellow liquid which freezes at about -20° , and boils at 102.5° . Air and moisture decompose it. The halogens give ferrous and ferric halides and carbon monoxide; hydrochloric and hydrobromic acids have no action, but hydriodic decomposes it. On exposure to sunlight, either alone or dissolved in ether or ligroin, it gives lustrous orange plates of diferrononacarbonyl, $\text{Fe}_2(\text{CO})_9$. If this substance be heated in ethereal solution to 50° , it deposits lustrous dark green tablets of ferrotetracarbonyl, $\text{Fe}(\text{CO})_4$, very stable at ordinary temperatures, but decomposing at 140° – 150° into iron and carbon monoxide. For the cyanides see PRUSSIC ACID.

Ferrous salts give a greenish precipitate with an alkali, whilst ferric give a characteristic red one. Ferrous salts also give a

bluish white precipitate with ferrocyanide, which on exposure turns to a dark blue; ferric salts are characterized by the intense blood-red coloration with a thiocyanate. Iron is estimated either by reduction to the ferrous condition and titration by potassium permanganate or dichromate, or by titration in the ferric condition by means of titanous chloride. (See also CHEMISTRY: Analytical.)

A. Werner prepared salts of ferrous tri-dipyridyl, $[\text{Fe}(\text{C}_{10}\text{H}_8\text{N}_2)_3]\text{X}_3$, which were resolved into dextro- and laevo-rotatory forms (see STEREOCHEMISTRY), and W. Thomas similarly resolved potassium ferrioxalate, $\text{K}_3[\text{Fe}(\text{C}_2\text{O}_4)_3]$.

MEDICAL USES

All the official salts and preparations of iron are made directly or indirectly from the metal. The pharmacopoeial forms of iron are as follow:—

Ferri sulphas exsiccatus, which has two subpreparations: (a) *Pilula ferri*, "Blaud's pill," (b) *Pilula aloes et ferri*.

Ferri phosphas, a slate-blue powder of ferrous and ferric phosphates with some oxide. Its preparations are: (a) *Syrupus ferri phosphatis*; (b) *Syrupus ferri phosphatis cum quina et strychnina*, "Easton's syrup," in which each fluid drachm. represents 1 gr. of ferrous phosphate, $\frac{1}{2}$ gr. of quinine sulphate, and $\frac{1}{8}$ gr. of strychnine.

Syrupus ferri iodidi, (strength 5-gr. of ferrous iodide in one fl.dr.).

Liquor ferri perchloridi fortis, strong solution of ferric chloride (strength, 22.5% of iron); its preparations only are prescribed, viz.: *Liquor ferri perchloridi* and *Tinctura ferri perchloridi*.

The scale preparations of iron, so called because they are dried to form scales, are three in number, the base of all being ferric hydrate:

(a) *Ferrum tartaratum*, dark red scales, soluble in water.

(b) *Ferri et quinae citratis*, greenish yellow scales soluble in water.

(c) *Ferri et ammonii citratis*, red scales soluble in water, from which is prepared *Vinum ferri citratis* (ferri et ammonii citratis 1 gr., orange wine 1 fl.dr.).

Substances containing tannic or gallic acid turn black when compounded with a ferric salt, so it cannot be used in combination with vegetable astringents except with the infusion of quassia or calumba. Iron may, however, be prescribed in combination with digitalis by the addition of dilute phosphoric acid. Alkalis and their carbonates, lime water, carbonate of calcium, magnesia and its carbonate give green precipitates with ferrous and brown with ferric salts.

There are numerous organic preparations of iron. Ferratin is a reddish brown substance which claims to be identical with the iron substance found in pig's liver. Carniferrin is a tasteless powder containing iron in combination with the phosphocarnic acid of muscle preparations, and contains 35% of iron. Ferratogen is prepared from ferric nuclein. Triferrin is a paranucleinate of iron, and contains 22% of iron and $2\frac{1}{2}\%$ of organically combined phosphorus, prepared from the casein of cow's milk. Haemoglobin is extracted from the blood of an ox and may be administered in bolus form. Dieterich's solution of peptonated iron contains about 2 gr. of iron per oz. Vachetta used the albuminate of iron with striking success in grave cases of anaemia. Succinate of iron has been prepared by Hausmann. Haematogen, introduced by Hommel, claims to contain the albuminous constituents of the blood serum and all the blood salts as well as pure haemoglobin. Sicco, the name given to dry haematogen, is a tasteless powder. Haemalbumen, introduced by Dahmen, is soluble in warm water.

Therapeutics.—Iron is a food and a medicine. Externally its salts are not absorbed by the unbroken skin, but when applied to the broken skin, sores, ulcers and mucous surfaces, the ferric salts are powerful astringents, because they coagulate the albuminous fluids in the tissues themselves. The salts of iron quickly cause coagulation of the blood, and the clot plugs the bleeding vessels. They thus act locally as haemostatics.

Internally, a large proportion of ordinary diet contains iron.

When given medicinally preparations of iron have an astringent taste, and the teeth and tongue are blackened owing to the formation of sulphide of iron. It is therefore advisable to take liquid iron preparations through a glass tube or a quill.

In the stomach all salts of iron are converted into ferric chloride. If given in excess, or if the hydrochloric acid in the gastric juice be deficient, iron acts directly as an astringent upon the mucous membrane of the stomach wall. Acid preparations are more likely to do this, and the acid set free after the formation of the chloride may act as an irritant. Iron, therefore, must not be given to subjects in whom the gastric functions are disturbed, and it should always be given after meals. Preparations which are not acid, or are only slightly acid, such as reduced iron, dialysed iron, the carbonate and scale preparations, do not disturb the digestion. In the intestine the ferric chloride becomes changed into an oxide of iron; the sub-chloride is converted into a ferrous carbonate, which is soluble. Lower in the bowel these are converted into ferrous sulphide and tannate, and are eliminated with the faeces, turning them black. Iron in the intestine is astringent or constipating and is therefore useful occasionally to check diarrhoea and dysentery. Salts of iron being constipating, they are best used in combination with a purgative. The pill of iron and aloes (B.P.) is designed for this purpose. Iron is certainly absorbed from the intestinal canal. As the iron in the food supplies all the iron in the body of a healthy person, there is no doubt that it is absorbed in the organic form. Whether inorganic salts are directly absorbed has been a matter of much discussion; it has, however, been directly proved by the experiments of Kunkel (*Archiv für die gesamte Physiologie des Menschen und der Tiere*, lxi.) and Gaule. The amount of iron in the human blood is only 38gr.; therefore, when an excess of iron is absorbed, part is excreted immediately by the bowel and kidneys, and part is stored in the liver and spleen.

Iron is prescribed when the amount of haemoglobin in the blood is lowered or the red corpuscles are diminished. In certain forms of anaemia its administration rapidly improves the blood in both respects, though the exact method in which it acts is a matter of dispute. In cases with toxæmia from absorption of intestinal products, not only laxatives in combination with iron but intestinal antiseptics are necessary. That form of neuralgia which is associated with anaemia usually yields to iron.

IRON AGE: see ARCHAEOLOGY.

IRON AND STEEL. Iron is the most useful metal of material civilization; it means plant, tools, machinery. It is principally used when alloyed with other elements, notably carbon; a moderate amount produces steel, an excess produces cast iron. Many special steels for particular uses have been devised in recent years; these steels contain a proportion of other metals, such as manganese or chromium (resulting in manganese steel, or chromium steel in these two cases, for instance). About 84 million gross tons of pig iron and 98 million gross tons of steel were made in 1927.

Outline of Manufacturing Process.—The source of commercial iron and steel is the oxide ores of iron, occurring in great abundance in all continents. This is charged into the top of a shaft-like blast furnace together with coke and some limestone. Hot air is blown into this furnace near the bottom, burning the coke and furnishing the gases and heat necessary to reduce the iron oxide to molten iron metal; trickling down over the white hot coke it absorbs an excess of carbon; drained from the bottom is the impure high-carbon alloy pig iron, which is merely remelted and cast into moulds to form the familiar iron castings of commerce. Limestone is charged into the furnace to convert earthy minerals mixed with the iron ore (gangue) and the coke ash into a fusible slag; this is also drained periodically from the furnace hearth. The blast furnace therefore operates continuously; solids are charged at the top, liquid iron and slag are drawn from the bottom.

To change pig iron into steel two methods are used extensively, the Bessemer converter and the Siemens-Martin open-hearth furnace. The converter is a brick-lined vessel, with perforations in the bottom through which air is blown. Into this vessel some molten pig iron is charged, and the air blowing through the metal

burns out the carbon and some of the other impurities; at these high temperatures there is a pronounced selective action so that relatively little of the iron is burned. Combustion of these impurities furnishes the necessary heat to maintain operations. At the end of the blow, a matter of ten to 15 min., the purified metal is dumped into a ladle, and an alloy of manganese and iron known as spiegel is added to degasify the melt, whereupon the finished steel is poured into ingot moulds. Refining pig iron in an open-hearth furnace is a much more deliberate process, requiring eight to ten hours. The furnace is a flat shallow basin with a low roof. At either end are ports through which gas and hot air enter; the flame sweeps through, out the ports at the other end, and thence into chambers filled with checker brick to absorb some of the waste heat. At intervals the flow of gases is reversed by suitable valves thus returning the recovered heat to the furnace hearth. Scrap and pig iron are placed in the furnace through side doors, and melted down. Iron ore and limestone are also added, and a series of chemical reactions take place between the iron oxide and the impurities in the metal; the latter either vanish as gases or accumulate in a scum of thin slag. When the reactions are complete the bath is tapped into a ladle from which the slag overflows, and the finished steel is then cast into ingots. Ingots are squat prisms of steel and are given marketable shape in the rolling mills. By successively passing between rolls with steadily diminishing apertures, bulky ingots are converted into long rods, bars, plates, rails or various structural shapes. Rather thicker bars are known as billets and are used in forge shops for hammering out more intricate pieces of non-uniform cross section. Specially shaped rolls and auxiliary machinery also convert bars into sheet-steel, plate into pipe, and rods into wire products.

EARLY HISTORY

Antiquity of Iron.—Few implements of iron or steel survive for many years before they rust away, consequently there is little direct evidence to prove the point; nevertheless the antiquity of iron smelting is great. It doubtless has been discovered and rediscovered many times; explorers reaching primitive peoples in many parts of the world find the native blacksmith using methods very similar to those known to other tribes at far distant times and places. An iron blade, probably 5,000 years old, has been found in one of the Egyptian pyramids. Even without this discovery one could plausibly maintain that the ancient Egyptians *must* have had skilled steel workers in order to have built the great pyramids and other monumental architecture, to say nothing of the statuary and hieroglyphics cut into the hardest rocks. Steel working and hardening, an advanced stage in the art which doubtless required centuries to reach, was common 3,000 years ago in Greece, and is mentioned in Homer. It is more probable that iron was first found in the ashes of a big fire built near some red paint-rock than that the first tools were made from meteorites. When paint-rock and fire came to be associated with iron as cause and effect, the next step was to produce it intentionally in fires built against a bank exposed to prevailing winds, or in pits or rude rock furnaces where the fires were fanned by bellows, one of the earliest mechanical devices.

These are the primitive methods which survive to-day in the Catalan forge (*q.v.*): a mixture of charcoal and iron ore, selected for its purity, is heated intensely for several hours, with fuel additions made from time to time, and a vigorous blast of air fanning the fire. The iron ore becomes an incandescent sponge of metal; the clay or other minerals mixed with the iron oxide together with the charcoal ash sinter into a slag, permeating the sponge and protecting the freshly reduced iron from further chemical action. After a given time, the furnace is broken into, the glowing ball of iron pulled out, and immediately, while still white hot, hammered vigorously to expel as much of the slag as possible, and to weld the hot particles of metal into a coherent mass.

Steel from Indirect Processes.—With various changes in the furnace details, and in methods of producing the air blast, these methods produced all the iron available from the beginning up to the 14th century. It was truly a *wrought* iron, the best product containing no more than 0.1% of total impurities alloyed with the

metal, but shot through with microscopic slag particles, aggregating 3% or more of the total weight. Steel was made sometimes as an accidental product in the old forges; by design the wrought iron bars would be packed with charcoal in clay boxes or jars, and heated for days, whereupon the iron absorbed enough carbon to become steel and thus acquired the superior hardness and strength necessary for keener tools.

As the demand for iron grew, the furnaces became bigger and a stronger blast of air was required to drive the products of combustion from the bottom up through the mixed charge. It resulted that the iron ore was reduced to spongy metal in the upper part of the furnace, and it then proceeded to absorb more carbon as the charge settled down, thereby converting itself to pig iron, a much more readily fusible alloy. The bigger, taller furnaces introduced in the early 14th century therefore produced liquid pig iron, a complex alloy of iron, carbon and other elements. Subsequent developments have been along three main lines; (a) increasing the size of the furnace and developing mechanical auxiliaries to produce pig iron more economically and in greater amounts, (b) invention of various processes for changing this impure pig iron into the more useful wrought iron, (c) production of steel either by way of wrought iron, or from pig iron direct. Sir Henry Bessemer's process, announced in 1856, for making steel from pig iron in a pneumatic converter, began the steel epoch. Cheap and ample supplies of steels in a wealth of sizes, shapes and surface finishes, grades of hardness, or types of alloy, are now available to meet the special demands of metal workers, machinery builders, or tool users.

Modern metallurgical developments have consequently been away from the simple and direct production of wrought iron to the complex indirect manufacture of steel. The change from the small, intermittent operations controlled by a highly skilled artisan to the large continuous furnaces, machine driven, has been associated with enormous expansion in total output and as great a saving in labour, and a notable conservation of raw materials.

Steel from Direct Processes.—Some metallurgists, however, believe that the excessively high temperatures attained in the modern blast furnace cause the pig iron to alloy with undesirable compounds, notably of nitrogen, which cannot be eliminated later, and which cause the present day metal to be markedly inferior to that produced by the old direct processes operating at a low temperature. Hence many methods of making iron and steel direct from the ore have been proposed since 1910, and extended experimentation on a semi-commercial scale has produced some marketable metal by these processes. Most of them rely upon the fact that iron ore is reduced by gas in the upper cooler part of the blast furnace. That is, the reaction

is substantially completed at 800° C, low red heat, too low to break up other minerals in the ore. Consequently hot iron ore is passed through a revolving kiln containing producer gas, and the iron sponge formed therein is either passed direct to an electric melting furnace, or quenched rapidly to prevent re-oxidation, separated from unreduced ore and gangue, and the metallic portion briquetted or melted. Whether these so-called direct steel-making processes are destined to supplant the present indirect system of smelting ore to an impure product, and refining the latter, cannot be predicted. In view of the great investment in the present plants for making steel which is reasonably satisfactory to the user, any innovation would have to show a considerable saving in costs, or have material collateral advantages, before it could be widely adopted. Such savings and advantages have not yet been demonstrated.

IRON ORE

Iron is smelted from several oxidized minerals occurring in abundance in the earth's crust. In order of commercial importance these minerals are hematite (Fe_2O_3), magnetite (Fe_3O_4), limonite (hydrated iron oxide) and the carbonate siderite (FeCO_3). Great deposits of these minerals in relatively pure state, close enough to the surface to be mined easily, occur in all regions. They are so common that an iron and steel industry will be devel-

oped whenever and wherever a population of machinery-using humanity accumulates. Iron deposits located in sparsely settled countries are potential ores of the future; for present uses an ore must be so situated and of such a nature that it can be mined, smelted by methods now known, and transported to market at a profit. Proximity to cheap fuel will enhance the value of ore—in Great Britain inland furnaces smelt local ores containing as low as 27% iron. The enormous ore deposits near Lake Superior in North America are a thousand miles from coking coal and an iron-consuming population, but intensive production and cheap water transport on the Great Lakes enables them to dominate the American market. On the other hand Brazil has huge untouched reserves of iron too far inland to export and with no home demand. The Continent depends upon the minette ores of Lorraine—ores which until the beginning of this century were valueless for steel making because no way was known to eliminate a high percentage of harmful phosphorus.

American Deposits.—The most productive iron ore region in the world is in very old (pre-Cambrian) strata surrounding Lake Superior, on the border between United States and Canada. Several long narrow areas called ranges contain the workable ores, which are hematites. Data on these ranges follow (production in long tons of 2,240 lb.):

"Old Ranges"					
Name	Location	Open- ed	Production in 1927	Total production including 1927	Greatest yearly production
				Million	
Marquette	Michigan	1854	4,171,000	160	5,396,000
Menominee	Michigan	1872	5,193,000	158	6,569,000
Gogebic	Michigan & Wisconsin	1884	6,390,000	167	8,763,000
Vermillion	Minnesota	1884	1,553,000	53	1,947,000
"New Ranges"					
Mesabi	Minnesota	1892	33,043,000	780	42,527,000
Cuyuna	Minnesota	1911	1,882,000	25	2,479,000

The deposits in the Mesabi range are flat, thick and close to the surface, and are therefore mined in open cuts by steam shovels. Underground mining is the rule in the others, the veins being fairly steep and worked to 3,000 ft. depth. The wealth of these ranges is such that ores of various analyses and textures are available. One-fourth the output is Bessemer ore, suitable for acid steel, containing on the average 55% iron and 0.04 phosphorus. The Cuyuna ore contains notable amounts of manganese. Basic or non-Bessemer ores from the ranges are higher in phosphorus and averaged 51.5% iron in 1926, with silica forming the principal impurity.

In view of the tremendous annual production of the Mesabi range, it may be questioned how long it will be before the region is worked out. The average iron content of all lake ores dropped from 55½% in 1902 to 51¼% in 1910, and has been maintained since then only by mining increasing amounts of high grade ore, and washing or screening one-third of the remainder. Minnesota, which is mining at the rate of about 40 million tons a year, is estimated by the State geologist to have demonstrated reserves of 1,250 million tons of recoverable ore. Unless these reserves are increased by new discoveries the Mesabi range will therefore be worked out by 1960. But any prediction about the age of a mining district must prophesy also the state of the future art of ore concentration—lean rock to-day may be workable ore to-morrow. In fact, this region contains an unlimited tonnage of magnetite-bearing strata just outside the classification of ore, as defined by conditions in 1927.

While seven-eighths of American ore comes from the Lake ranges, the balance of about eight million tons is taken from many ore occurrences in the Clinton formation in the Appalachian mountains, an uplift which parallels the Atlantic coast from north

to south. In the northern region the ores are predominantly magnetites; at the southern end in the State of Alabama, deposits of a low-grade red hematite with an easily fusible gangue are found near extensive coal measures. All these deposits are mined by underground methods; among them are mines which have produced continuously since the earliest iron smelting in America.

Lorraine Deposits.—Ore beds second in importance only to those in the Lake Superior region occur in strata of Mesozoic age near the Franco-German border, extending northward into Luxemburg and Belgium. They are of recent commercial development. While only 830,000 tons were produced in 1897, they are now the chief ores for the French, Belgian, German and Luxemburg blast furnaces which together in 1927 produced 36% of the world's pig iron. Mining is done in three principal basins, Longwy near the Belgian border, Briey, and Nancy at the south. Previous to the World War much of this area was German territory, and practically all of the rest was promptly overrun and occupied by the invading army. Possession of this all but essential region was thereafter one of the aims of the contending Powers. Great damage was done during the occupation and the retreat, and not until 1926 did the area approach the productivity of 1913. While the output of the region exclusive of Belgium and Luxemburg was about 40 million tons in 1913, equally divided between France and Germany, the French department of Meurthe-et-Moselle was able to hoist only 5 million tons in 1920. Recovery of the reunited provinces has been so rapid, however, that the output of ore reached 37 million tons in 1926. The ore beds occur in flat strata 60 to 120 ft. thick, from 300 to 750 ft. below the surface. The iron is contained in tiny nodules of hematite, cemented with a calcareous or a siliceous gangue. It is only necessary to combine these two to procure a self-fluxing, easy smelting mixture, very desirable commercially even though its iron content is quite low. Representative analyses, after driving off 8 to 12% moisture, are as follows:

	Siliceous ore	Calcareous ore
	%	%
Iron	35 to 37	38 to 42
Silica	12 to 18	4 to 8
Alumina	3 to 7	3 to 7
Lime	3 to 7	9 to 13

Phosphorus is strikingly uniform, being 1.7 to 1.9% of the iron contained, and the Lorraine pig iron must therefore be used in basic steel making.

Ores in Great Britain.—Since the rich blackband, clay iron stone and brown hematites of the Carboniferous strata have been almost exhausted, 80% of the iron ore mined in Great Britain is now taken from leaner strata, averaging only 27½%, which are a continuation of the Lorraine beds. Workable deposits extend in a broad strip from the coast of Yorkshire south-west to that of Dorset and are estimated to contain 3,400 million tons of workable ores. The beds are nearly horizontal, and consequently have broad outcrops in gently rolling ground, thus permitting them to be mined by quarrying operations. As a rule the individual deposits are small, and do not warrant the powerful excavating machinery installed in the great Mesabi pits. A maximum working face is 30 ft. Such "marlstones" (or simply "stone") contain the iron in tiny ooliths like the Lorraine ore, but near the surface the iron has been oxidized and hydrated to limonite, and at depth is a carbonate. Gangue materials are either calcareous or siliceous. These deposits have been longest mined at Cleveland, and here a limited area has produced 5½ million tons a year since 1875. All mining is underground in carbonate ores sometimes as deep as 600 ft.; 9 to 12 ft. beds are reckoned excellent. A governmental survey made in 1918 found only 200 million tons of recoverable ore here in reserve. An average analysis follows:

Oxide (FeO)	28%*
Silica (SiO ₂)	12%
Alumina (Al ₂ O ₃)	10%
*(24.6 to 33.3%)	

Lime (CaO)	5%
Sulphur	0.26%
Phosphorus	0.47%
Water	6.8%

Cleveland ores therefore are suitable for basic steel making, wrought iron manufacture or general iron foundry work. Except for the several post-war years of acute industrial depression, Great Britain's ore demands have been about stationary since the turn of the century. Each year Cleveland hoists 5½ million tons, other regions dig 9 million tons and 6 million tons are imported, principally low phosphorous ore from Spain and Sweden.

Future Stores of Iron.—Whether there is any likelihood of exhausting the available iron ore is a question which has occupied some minds. From the above remarks, it may appear that certain regions, such as the Mesabi range and the Cleveland beds, may be exhausted in the near future. However there is little to fear but that other deposits, only slightly less favoured, will supply the gap. Conservative estimates by economic geologists indicate that there are now about 30 billion tons of ore in reserve, which at the present annual consumption of 100 to 125 million tons, should last 200 years. Of this huge tonnage, two-thirds is located in the Western hemisphere; Brazil and United States possess most of this, but Newfoundland and Cuba both have notable deposits; France has half the balance, and the rest is scattered about in readily accessible locations. All such computations assume a certain state of metallurgical art in order to define ore. But metallurgical art is constantly advancing. Since so large a proportion of the earth is iron, it is safe to say that in the future, as in the past since before history began, the mind of man will always find means to win from mother earth this most useful metal, in supply ample for his current needs.

PREPARATION OF ORE FOR SMELTING

Transport.—In England and on the Continent much of the iron ore is smelted in furnaces erected nearby—even at the mine mouth. Freight is a minor matter. That which is transported from overseas is handled for the most part in ordinary cargo vessels. In America, however, the long haul down the Lakes from the ranges to the furnaces has caused the development of very specialized handling equipment. At the mines, hopper-bottom railroad cars of 50 to 60 tons capacity are loaded by steam shovels in the pit, or from storage bins at the mine, and hauled to the nearest port. Here long lines of ore bins are built out into the water; whole trainloads of ore are dumped in a few minutes by pneumatic devices. When these bins are full an ore boat docks alongside, opens her hatches, and a load of 10,000 tons of ore is spouted into her in less than a half hour. Ore boats that are used for service on the relatively calm Great Lakes are of special construction and are essentially long, self-propelling barges with a movable deck. Arrived at its destination, the hatches are again opened, and enormous grab-buckets reach through into the hold, scooping out the ore and dropping it inshore, either in railroad cars, or on a stock pile. If the furnace plant is inland, trainloads of ore are hauled to the site, and dumped in bins or placed in stock piles. Hopper-bottomed cars are used almost exclusively for this purpose, although for stockpiling it is generally found better to install a car-dumper, which turns the car upside down, and then to move the ore to the pile by a grab-bucket and overhead bridge. One cannot comprehend the magnitude and power of this unloading machinery, unless it has been seen in operation. Large stock piles, which are almost unknown elsewhere, are the general rule in America, where water transportation is entirely suspended by ice during the winter months. Limestone and coke are also stocked in sufficient quantity to provide against irregular deliveries from a distance.

Dressing.—Up to the beginning of the 20th century iron ore was seldom treated in any way prior to its utilization. High grade materials, however, are becoming increasingly scarce, and the future will see a rapid extension of ore dressing methods.

Screening is the simplest method. Some 17 million tons of Lake ore were improved by this method in 1927. In England as well the miner frequently digs marlstone without removing the

BY COURTESY OF THE WELLMAN-SEEVER-MORGAN COMPANY, CLEVELAND, OHIO

FIG. 1.—DIAGRAMMATIC ELEVATION OF BLAST FURNACE WITH AUXILIARIES AND STOCK PILES

loamy overburden; the quarried material is then crushed, and the fine particles screened out and discarded. In this way the average iron content of the ore is increased, and the suitability for smelting improved, for too many fines in the charge slow down blast furnace operations.

Washing is also common in America. This is an application of the water concentration methods so highly developed in ore dressing (*q.v.*) used at copper, lead and zinc mines. Some five million tons of Mesabi ore were treated in log washers in 1927. The washer is an inclined trough; from end to end is a stout shaft or log, with plow blades so set on its circumference that when the shaft revolves the plows clear the trough bottom and move any solid material gradually along. The fine screenings enter at one end, and travel against a copious current of water, which washes out the finer, clay bearing particles, lean in iron.

Calcining is common in England, particularly on the Cleveland carbonate ores. A Giers kiln is ordinarily used, a short cylindrical steel shell set vertically, and lined with fire brick. A mixture of ore, with about 5% slack coal, is charged through the top as the burned ore is withdrawn at the base. Such a kiln will drive moisture and carbon dioxide from about 1,000 tons of ore in a week; Cleveland ores lose 27 to 30% in weight, but the resulting ore has had its iron percentage increased thereby to about 31%; still a very lean ore, viewed by American standards. Lorraine ores contain much moisture, but cannot be calcined, because this preliminary heating causes them to fall to powder.

Sintering is a method of converting fine ores or flue dusts into a porous clinker which can easily be smelted. American and Swedish magnetite ores, low in grade, are frequently concentrated by fine grinding, and drawing the iron bearing minerals out of waste rock with strong magnets. This fine magnetite is then moistened and mixed with fine coal and a little flux or with blast furnace flue dust, and spread over a travelling grate, the coal ignited and burned in a strong down-draft. The resulting clinker smelts so much more easily than the dense magnetic ores that the latter, even of high grade, are frequently sintered at the American plants.

BLAST FURNACES

Having followed thus far the mining, transport and preparation of ore, attention should next be given to the process of smelting

it into metal. In the present state of the art, this is done in a blast furnace, and the metallic product is a high carbon alloy of iron called pig iron and containing more or less silicon and manganese. Since an article is devoted to the construction and operation of the blast furnace (*q.v.*) these matters will be summarized only briefly here; more attention however will be given to that entire assemblage of auxiliary equipment (*see fig. 1*) which together goes to form the blast furnace department of a modern steel making plant. A blast furnace is a structure often topping the general ground level by 100 ft. It is round in cross section, bound with steel plates, and lined with a thick wall of special fire brick. Piercing the very top of the shell are two side openings leading into brick lined pipes—downcomers—for venting the furnace gases. The top is closed by a double bell, which in effect is an air-lock for introducing charges of ore, coke and limestone, while permitting no gas to escape. Charging is continued at such a rate that the furnace shaft is always full. About 8 ft. above the furnace base is a series of 10 or 12 water-cooled nozzles called tuyères, equally spaced around the circumference, through which hot air is blown into the interior. The coke in the mixed charge burns in this air, producing a region of intense heat sufficient to melt the metallic iron descending to that level from above, and superheat it so much that when it trickles to the hearth it collects at the bottom of the shaft in a pool which remains molten for hours. Five or six times a day this iron is drawn off or cast by opening a tap-hole at the very bottom.

Reduction of Iron Ore.—Much study has been given to the chemical reactions which reduce the ore to iron. At the tuyères the heat is so intense that coke burns only to carbon monoxide, thus:

It is this gas which reduces the ore, and at a fairly low temperature, *i.e.*, near the top, by a series of reactions which may be simplified as

The secret of rapid furnace driving to produce big tonnages is to use such ore, or prepared sinter, that the gases may permeate it readily and completely. Pure iron is relatively infusible—melting point 1,530° C; when alloyed with 4.3% carbon its melting point

is about $1,150^{\circ}\text{C}$. The freshly reduced iron in the blast furnace picks up this necessary carbon to convert it into the more fusible pig iron, either by physical contact with the hot carbon, or by the gas reaction

a reaction which is the basis of the case-hardening phenomena. By no means all the CO is oxidized to CO_2 by the furnace reactions. A typical analysis of the gases from the furnace top is

Carbon monoxide (CO)	24.5%	by volume
Carbon dioxide (CO_2)	12.0	
Hydrogen (H_2)	1.25	from moisture in the air blast
Methane (CH_4)	0.25	
Nitrogen (N_2)	62.0	

rich enough in the combustible gases CO , H_2 and CH_4 to be valuable as a fuel. Leakage must be carefully avoided, for the monoxide content makes it highly lethal.

Slag Formation.—Impurities in the ore and the coke ash must also be disposed of. They consist of earthy substances like clay. If they contain a preponderance of a single oxide like silica (SiO_2) they cannot even be melted unless sufficient limestone is present to flux them—that is to say, convert them into an easily fusible glass or lava-like substance called slag (*q.v.*) or cinder. The formation temperature of slag depends upon the relative proportion of basic oxides (lime CaO , or magnesia MgO) and acid oxides (silica SiO_2 , or alumina Al_2O_3) which are present in the furnace charge. The operator therefore chooses his ores and fluxes with the aim of producing a slag which works well at some temperature, which he does not measure, but which he knows will produce the kind of pig iron which is demanded by his customers. Like the iron, slag melts in the hot region above the tuyères and trickles down, forming a pool floating on the iron. It is tapped or flushed through a cinder notch located between the tuyère line and the furnace bottom: usually just before the iron is tapped.

Ore Handling Equipment.—A furnace making 600 tons of pig iron a day will consume 1,160 tons of ore, 580 tons of coke, 290 tons of limestone, and 2,370 tons of air blast. It produces in addition to the iron, 330 tons of slag, 70 tons of dust and 3,400 tons of gas. It requires 17,000 tons of water to keep the furnace parts cool and to wash the dust from the gas. Therefore equipment must be provided to handle expeditiously no less than 26,000 tons of material each 24 hours. Such auxiliaries are so large and so numerous that the furnace itself is frequently inconspicuous, despite its huge bulk (fig. 1). In America, much space is ordinarily given to stock piles. Ore that comes from such storage, or direct from the mine, is dumped into bins alongside the furnace. Other compartments hold coke and flux. On a track underneath operates a scale car, which stops under appropriate gates and the attendant draws off a specified amount. When the proper quantities have been assembled, the car proceeds to the skip pit, and drops its load into a car which in turn is hoisted up the inclined bridge and dumped into a hopper at the very top of the furnace.

Furnaces a century ago were usually built on sloping ground, and the ore and charcoal wheeled off the hill top and dumped into the furnace. Later, when the value of the gases was discovered, a single bell was used to close the furnace top, and as the tonnage requirements increased, ore, coke and flux were shovelled from stock piles into carts, which were then pushed to the furnace, hoisted on platform elevators, and dumped by hand. Material handling by machinery is essential for furnaces making more than a hundred tons of iron a day.

Disposal of Iron and Slag.—In view of the congested surroundings, the pig iron and slag tapped from a big furnace are led by clay-lined troughs or runners to the edge of the foundation where they flow into ladle-cars standing below, and are hauled away while still liquid. If the furnace is serving a steel-making plant, the iron may be taken direct to a steel-making furnace. More usually it is poured into a mixer that is in effect a storage reservoir, sometimes of 1,500 tons' capacity. A mixer is usually shaped like a huge barrel, made of strong steel plate and lined with fire brick; it may be rolled on its foundation by suitable trunnions so the opening may at one time receive metal

from a ladle-car above, or later discharge it into another for transfer to the steel furnace. The bad effect on steel-making processes of sudden variations in composition of the pig iron, so-called off casts, is minimized by dilution in a pool of reserve metal. Furthermore, some of the harmful sulphur may be eliminated from high manganese pig iron in the mixer, if the temperature is properly controlled. Iron which cannot be converted promptly must be cast into pigs. Much of this work is done by machinery. A pig casting machine is an endless chain to which is attached a series of moulds. A ladle-car of iron pours slowly as this conveyor moves underneath. After the iron is chilled, the conveyor passes through a long water tank for more rapid cooling. When the chain moves over the tail pulley the moulds turn upside down and the now solid pig iron drops into a railroad car. Some furnaces specializing on foundry iron, and of rather limited tonnages, run their iron direct from the tap hole into pig moulds formed in the sandy floor of the furnace house (see *Pig Iron*). Slag may be hauled to a nearby bank, dumped and wasted. In some localities, the slag may be marketed for railway ballast, filling material, or concrete aggregate. It would then be run molten into a water sump, the stream being broken up by a strong jet of water. Granulated in this manner, it can be reclaimed by grab-bucket and crane and shipped. Since the slag is essentially a calcium aluminium silicate, large tonnages are utilized as raw material in the manufacture of Portland cement.

Utility of Blast Furnace Gas.—As noted above, gases from the furnace top are good fuels, but they bear too much dust to be used without cleaning. Even when burned under boilers it is found that dust will fuse to the water tubes, reducing the efficiency of heat transfer and increasing the cost of maintenance to a prohibitive figure. For use in internal combustion engines, the cleaning must be even more complete. Much of the coarser ore and coke particles swept out of the furnace with the gas remains in the dust catchers, one or two cylindrical tanks placed in series just alongside the furnace proper. Essentially they are enlargements of the downcomer pipes; the velocity of the gas and its carrying power are reduced in passing through them. A change in direction of travel also aids in catching solids, which as they accumulate are drawn off from the hopper-like bottom. Usually the reclaimed dust is mixed with fine ore, sintered, and resmelted. Formerly it was usual to send hot gas from the dust catchers direct to the stoves, but lately more and more furnace managers have been convinced that this rough gas contains entirely too much dust for this purpose, and the efficiency of the heat transfer suffers therefrom. Consequently further cleaning, either by scrubbing towers, by electrostatic precipitation, or by filtering through bags is now commonly undertaken. Electrostatic precipitation has the advantage that it handles gas without cooling it and may recover valuable amounts of potash for fertilizer. In this process the slightly humidified gas is passed through vertical pipes; in the centre of each is a wire charged at high voltage. In the electrical field so formed solid particles drift toward the grounded pipe walls, adhering there until dislodged by hammering.

Fig. 1 shows a scrubber, of which two would be required, each about 80 ft. high by 12 ft. diameter. By means of spray nozzles and screens the ascending gas is intimately mixed in these towers with fine particles of water. The dust content, which on entering is about 3.5 grains per cu. ft. is washed out except for about 0.2 grain. A powerful fan is necessary to draw the gas through the scrubber and to give it the necessary delivery pressure; water jets are introduced through the shell at several places so the fan acts as a further cleaner, delivering gas to stoves or boilers with about 0.05 grain of dust per cu. ft. Frequently all the gas is burned in this way, utilizing the steam so generated to drive blowing engines or electric generators. When it is desired to use the heat more efficiently, internal combustion prime movers may be installed (see *GAS ENGINES*) whereupon an even cleaner gas is required. Dust may be reduced to less than 0.01 grain per cu. ft. by a rotary washer, which is a combination turbo-blower and cleaner. The large amount of water used for these cleaning purposes may be again used after passing it through a cooling tower and settling basin.

BLAST FURNACE PLANT

Blowing Engines.—Fig. 1 indicates the essential steps whereby the energy contained in the furnace gases is utilized to generate hot blast and auxiliary power for pumping, hoisting and lighting. Cleaned gas is used to drive gas engines direct connected with compressor cylinders. Compressed air goes to the furnace by way of a stove, therein acquiring a temperature of some 550° C. and on through a brick lined hot blast main to a bustle pipe circling the furnace. From the bustle pipe gooseneck connections deliver blast to the furnace through the tuyère openings. The required amount of air is fixed by the size of the furnace and the pressure, which varies from 12 to 20 lb. per sq. in. with operating conditions, and must be delivered without fail. About 50,000 cu. ft. of air per min. is necessary for a furnace making 600 tons of pig iron per day (see BLOWING ENGINES).

Dry Blast.—One auxiliary (not shown in fig. 1) more commonly installed in Great Britain, although proposed by the American James Gayley, reduces the humidity of the blast. Gayley showed that water vapour entering the tuyères, amounting in summer to about 250 gals. per hour, is dissociated into its elements by the white hot coke, this action absorbing heat not usefully regained within the furnace. Variations in moisture content are especially undesirable, for these produce variations in the temperature at the focus, and consequently change the chemical composition of the pig iron. To produce a low and uniform humidity in the air blast, the compressors may suck air through an adequate refrigeration system. (See AIR CONDITIONING.) Silica gel has been proposed as a more proper medium to dry the air blast.

Stoves.—Four stoves are usually installed to heat the blast. These are steel cylinders up to 100 ft. high and 22 ft. diameter. Each has a vertical combustion chamber, either at side or centre; the burned gases then return to the bottom through a multitude of narrow flues made of fire brick (see COWPER STOVE). In the passage they give much of their heat to the brick work, and flow off through a chimney. In operation (fig. 1), stoves B, C, and D may at any hour be filled with burning gas, thus acquiring heat; the cold blast passes through one of them, stove A; when this one cools off, valves are changed in a certain order, to prevent accumulation of explosive gas-air mixtures; stove A will then be on gas, *i.e.*, heating; stove B will be on wind, *i.e.*, giving up its heat to the air passing through it enroute from engines to furnace. Usually valves are changed every hour. In a four-stove installation, therefore, each stove is heating for three hours, and cooling for one. Many designs have been proposed for the method of building the stove interior. A two-pass stove is simplest, and most favoured in America, where the trend is to use cleaner gas, injected with a regulated amount of air for combustion, through carefully designed burners. Cleaner gas permits much smaller chequer-work, higher heat capacity, longer life before the openings are plugged with fused dust, frequently enabling satisfactory furnace operation with only three stoves. A three-pass stove, where the gas is introduced at the bottom, goes up, down, up again and out a short stack built on top the stove, is favoured by some designers. (See HOT BLAST.)

Valves for handling these furnace gases are of special construction. On the cleaning system a water valve is favoured. As shown in the diagram of the blast furnace department, it is nothing much but a large pot with a diaphragm extending from top toward the bottom. To close this valve it is only necessary to fill the pot with water until the bottom of the diaphragm is submerged several inches; draining the pot opens the valve. Valves for handling hot blast are more difficult to construct and to maintain in good condition. Also, since the valve seat is exposed to the corrosive action of hot gases, it requires occasional replacement. This can be done by loosening all the turnbuckle clamps, wedging the flue sections apart, and sliding the old seat out sideways. The valve disc is also a hollow copper casting with spherical bottom; cooling water enters the hollow stem as shown. To open the valve it is only necessary to lift the disc up until it strikes the bricked dome. All blast furnace stoves have four valves. Two are shown on stove A (fig. 1); stove A is on wind, the chimney valve and the gas burner opening being closed. Stove B is on gas; the chimney valve

is open, the gas burner in place, and the valves into the cold and hot blast mains are closed.

Blast Furnace Operation.—From the foregoing description it may be surmised that the blast furnace superintendent's task is primarily to harmonize operations of various large mechanical elements. But the furnace itself is his greatest care, even though the principal reactions within it are in virtual equilibrium. Slight variations from normal are self-adjusting—that is to say, if for some reason a surplus of heat is generated, the action within the furnace changes in the direction which will absorb that extra quantity of heat. Nevertheless the skilled operator is quick to observe clues which indicate deviations from the normal, and he immediately makes such adjustments in the operating conditions as experience tells him will avoid any serious irregularity. A hundred years ago his problem was simpler. His furnace plant consisted only of stack and blower; his ore was pure and rich, carefully selected by hand; his fuel was charcoal, ideal in character; the driving rate was slow; under such circumstances his pig iron was relatively free from impurities. Even to-day some of this charcoal pig iron is made in small furnaces with either cold blast or hot blast, and is favoured by foundrymen for castings which require a dense, tough and strong body, or by manufacturers of high grade tool steels. Rich ores and forests were very soon exhausted, however, and the progress of metallurgy has been associated with the ability to recognize the specific effects of each disturbing element and to devise ways and means to utilize the impure ores and coke fuel remaining. For many of the minerals entering the furnace top with the iron ore are broken up and the elements therefrom alloy with the pig iron, often to its detriment.

Control of Sulphur.—Sulphur, largely from iron pyrite contained in coke ash, is the worst offender; if left in the iron causes it to be very tender at red heat (red short). High sulphur castings often crack in the moulds after cooling, and high sulphur steels may break when being worked in rolls or forging. Since no sulphur is removed in the converter or open-hearth steel making processes, it is essential that this undesirable element be eliminated from the blast furnace. This is done by charging enough limestone so the slag shall be distinctly basic, and thus have a higher solubility for sulphur compounds. Such a slag requires a hotter furnace for its operation and this surplus heat also helps drive the sulphur into the gas or slag. Once in the iron, its harmful effects may be mitigated in castings if two or three times as much manganese is present; an innocuous manganese sulphide results. In steel, zirconium has been found to have the same effect. Sulphur may be eliminated in electric furnace steel by refining at a high temperature under a slag very high in lime and containing some calcium carbide. Pig iron for grey iron castings must therefore have less than 0.10% sulphur; structural steel must contain less than 0.06%; many alloy steels are specified to contain less than 0.04% sulphur.

Effect of Silicon on Pig Iron.—A blast furnace working very hot tends to reduce silicon and manganese from any minerals containing them present in the charge. Manganese is now considered beneficial in all subsequent processes. But silicon must be sharply limited to pass some specifications. Silicon in pig iron causes much of the carbon present to separate and collect into tiny flakes of graphite, permeating the entire metallic structure; this graphite is responsible for the characteristic grey fracture of castings for machinery; its presence also makes for easy machineability. If not present, the carbon would exist in the alloy as a compound of iron, a carbide, Fe_3C , called cementite, and form a much harder, stronger alloy. Consequently in such things as car wheels or in white iron castings, which are later to be converted into malleable iron (*q.v.*) by annealing, the silicon must be strictly limited. Silicon in pig for Bessemer steel must also be under close control, as we shall presently see. Therefore for those irons where both sulphur and silicon are limited, the ore and fuel must be specially selected for a low content of sulphur.

Grey and White Iron.—Carbon is another element in pig iron which will vary somewhat. It may be from 3.0 to 4.25%, depending upon furnace conditions. Generally if either silicon or phosphorus runs unduly high, the carbon will be low. Manganiferous

BESSEMER CONVERTER IN FULL BLOW

The converter or furnace, into which molten pig-iron is poured, is lined with brick having perforations in the bottom; through these a powerful blast of air enters and passes through the molten metal, thereby oxidizing the impurities, which if liquid, go into the slag, or if gaseous, out of the mouth of the converter. After 10 or 15 minutes "blowing" the metal is poured into ingots. This quick and inexpensive method of manufacturing steel, invented by Henry Bessemer in 1856, has greatly influenced modern industry

PROCESSES IN THE MANUFACTURE OF STEEL PRODUCTS

1. General view of large steel plant in eastern Pennsylvania, showing open hearth and blast furnaces, and rolling and finishing mills
2. Pouring molten steel into electric furnace. Ladle travels on overhead crane from smelting furnace. This process prepares steels of special quality
3. Blooming mill with 54 in. rolls in structural steel mill. Roller tables (foreground) carry hot bloom between manipulators. Top roll (background) depressed after each rolling by power driven screw press
4. Skelp, or steel plate, being fed into furnace for manufacture of butt welded steel pipe. Furnace door, left; feeding table, centre
5. Pipe emerging from furnace after passing through the welding bell, which draws the hot plate into welded pipe
6. View of soaking pit department at steel plant, showing hot ingots being drawn from pit by overhead travelling cranes leading to rolling mills
7. Continuous merchant mill. Hot billets from furnace passing through first three roughing rolls (centre). Finishing train and runout tables (right) convey the rods or bars to saw and cooling beds in distance. Entire train of mills is driven by covered gearing (left) and main motors in glass enclosed room (top)

irons, on the other hand, are usually high in carbon. The colour of a freshly broken piece of pig iron is due to the way the carbon is held, rather than its total quantity; in white iron, nearly all the carbon is combined with iron in the carbide cementite; in grey iron, seven-eighths of it is in the form of graphite; intermediate proportions are called mottled irons.

Phosphoric Ores and Iron.—Phosphorus, until about the turn of the century, was the most undesirable element entering the blast furnace. Whereas much sulphur can be slagged off, between 90 and 100% of the phosphorus entering with the ore and the fuel ash comes out with the iron. Phosphorus makes both iron castings and steel brittle. For some types of thin castings requiring fluid iron e.g., stove plates, from about 1.0 to 1.5 % of phosphorus may be permitted, but in steel it is kept as low as sulphur, namely from 0.02 to 0.07%; the lower the analysis the better the steel. Consequently the phosphoric iron ores of Lorraine were of small value—in fact of no value for steel-making until the Thomas-Gilchrist basic process was suggested (1878). Subsequent developments have converted the phosphorus in the ore to a pronounced economic asset. In view of all these facts, the furnace operator selects and mixes the ores and fuels which are available to him, and then adjusts his flux and controls his hearth temperature, by varying the amount of coke charged and the temperature of the blast, so the desired kind of iron will issue from the tap hole (see CAST IRON). Further notes on the varieties required for the various conversion processes will be given later.

WROUGHT IRON

Wrought iron, as compared to the total tonnage of steel, is an unimportant commodity. It amounts to less than 3% of the total production of steel. But it is important for its unique combination of physical properties, enabling it to survive since the time 75 years ago when it was the principal metal of engineering construction.

Puddling Process.—If about 600 lb. of pig iron and considerable iron ore are placed on the hearth of a small reverberatory furnace and melted, various reactions occur between the iron oxide from the ore and the impurities in the droplets of pig iron. The first reactions to occur may be simplified as follows:

The iron thus reduced from the ore enters the pool of metal, and the silicon and manganese oxides join with the surplus ore to form a highly basic slag. This slag has the ability to absorb any phosphorus oxides which result from reactions between the phosphorus alloyed in the metal and the surplus iron oxide in the slag. The workmen stir the slag and iron together, an operation which is known as puddling; after the silicon and manganese have been substantially eliminated from the metal the carbon content begins to go down. The reaction may be written as follows:

Carbon monoxide gas bubbling upward causes the bath to boil. Removal of all these alloying elements leaves practically pure iron, of a much higher melting point. Toward the end of the process, therefore, the bath is converted into a metallic sponge of white hot, pasty iron, filled with liquid slag. This is cut into 200 lb. balls by the furnaceman, surplus slag squeezed from the dripping mass, and the resulting balls rolled into flat muck-bars. The metal is hot enough to weld together satisfactorily, and the process is accompanied by a great spray of slag sparks, squeezed out by the rolls. Muck-bars are cut to short lengths, arranged and wired together in piles, heated to a welding heat and re-rolled into marketable shapes.

Nature of Ferrite.—From a knowledge of the manufacturing process it may be understood that commercial wrought iron is essentially pure iron containing a greater or lesser number of slag particles.

The chemical changes which occur in the process of refining are thus indicated:

	Forge pig iron	Metallic portion of wrought iron
	%	%
Carbon	3.5 to 4.25	0.02
Manganese	0.25 to 1.0	0.005
Phosphorus	0.5 to 1.0	0.07
Sulphur	0.03 to 0.10	0.02
Silicon	1.0 to 2.0	0.03
Iron	95 to 92	99.855

About 3% of the wrought iron by weight is slag.

A view of a polished section through a microscope shows the structure of wrought iron (Plate III., fig. 9). The mirror-like metal appears white in the photograph; the stony lustre of the slag particles appears grey. The slag itself is not a simple glass, it is a high iron silicate containing more or less manganese and phosphorus and frequently develops well crystallized minerals. Slight etching of the polished surface under examination develops characteristic markings; the metallic portion seems to consist of a number of closely fitted or interlocking grains. If one of these grains were picked out, it would have an irregular surface; nevertheless it is undoubtedly true that its inner structure is that of a true crystal—that is to say, the ultimate atoms are arranged in regular rows and ranks, in geometric order. Such tiny crystals of substantially pure iron are called ferrite.

Properties of Wrought Iron.—Wrought iron has superior properties for forge welding, because at high heats the slag particles melt and spread into a film protecting the metal from atmospheric oxygen. The purity of the iron is responsible for great toughness, resistance to shock and bending. It also resists atmospheric and aqueous corrosion, either by virtue of purity of the metal or by virtue of the slag inclusions, or for some other reason. These special properties cause it to be in demand for pipe, chain cable, boiler stays, sheet iron and blacksmith's bar iron. For some of these purposes a variety known as charcoal iron (*q.v.*) is preferred. Wrought iron is moderately strong in tension, developing from 45,000 to 55,000 lb. per sq.in. ultimate strength. Furthermore it is a soft metal—Brinell hardness measuring 75 to 80. Likewise the production of big masses of it is tedious, and puddling requires a large amount of exhausting labour from skilled workmen. These facts all combined to hamper competition with the harder and stronger steel—the Bessemer's process showing how to make the latter in great quantity, rapidly and almost automatically. In 1883 70% of all the pig iron made in England was made into puddled bar; in 1897 only 5%.

Aston's Process.—Mechanical puddling furnaces have been proposed and used to some extent, but the manufacture of metal in small batches is not in keeping with modern mass production. A more promising development consists of the process established in 1927 in America through James Aston. Knowing the essential characteristics of the ferrite and slag constituting wrought iron, he produces pure iron in a Bessemer converter, following the regular steel-making practice, and pours this iron into a pool of synthetic slag, which has been melted in a large cupola. Strong evolution of gas in the metal causes it to granulate itself into very fine particles; the resulting spongy mass of iron and slag is withdrawn, squeezed and rolled in the conventional manner.

BESSEMER STEEL

Early Steel-making Processes.—Prior to 1870 the principal metallic materials of construction were cast iron and wrought iron. The former could be made quite hard, but then was brittle; the latter resisted shock excellently, but was comparatively soft. There was a great and growing demand for metal which was both strong, wear resisting and tough, but there was no method of producing cheaply enough to make, for example, railroad rails. Consequently, the discovery of the Bessemer process for making cheap steel was a godsend—an eager market was waiting; and in turn the satisfied market created other demands. Steel had been known for centuries. While accurate statistics are lacking one may reasonably guess that 250,000 tons a year of blister steel and crucible steel were being made in Europe in 1865. Blister steel

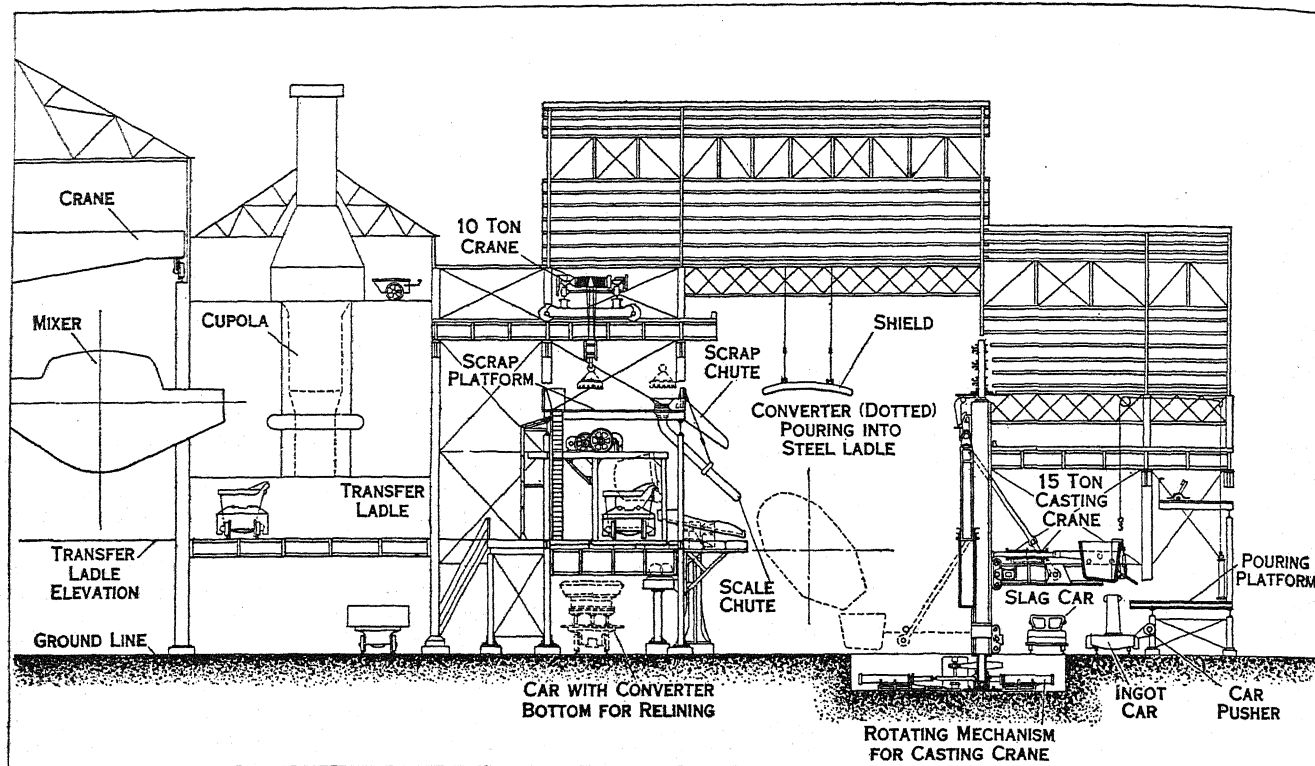

FIG. 2.—GENERAL CROSS SECTION OF CONVERTER HOUSE

was, and still is, made by packing wrought iron bars in a long stone box full of charcoal, and heating the container for several days at a full red (*see* BLISTER STEEL; CEMENTATION). Carbon gradually is absorbed by the iron under these conditions, and it becomes steel. In order to improve the quality by equalizing the carbon content in this steel, and also eliminating the slag contained in the original wrought iron, blister steel is cut in short lengths and melted in a clay crucible (*see* CRUCIBLE CAST STEEL). For the manufacture of fine tools and cutlery such processes survive even yet, principally in the Sheffield region where the industry thrived a half-century ago. But obviously this very indirect method of getting steel, bit by bit, was totally incapable of supplying the needs of the coming mechanical age.

Bessemer's Invention.—As has been pointed out the alloyed impurities in pig iron can be eliminated by oxidizing them. In all the old refining processes, iron oxide in the form of ore, mill scale, or iron silicate slag (basic cinder) is the means whereby the necessary oxygen is carried into the pig iron under purification. While experimenting on some methods for improving metal for cannon in 1856, it occurred to the English inventor Henry Bessemer that this oxygen for refining could be taken directly from the air if a blast were blown on or through the melted pig iron. On trial it not only purified the iron, but instead of blowing cold and freezing, the metal became hot enough to remain molten even when all the carbon was gone and hitherto infusible pure iron remained. The whole reaction required only a few minutes; at the end an ingot of mild steel could be cast, ready for the forge or rolling mill.

It took years of experimentation before the new process became a commercial success. The conservatism of engineers and constructors retarded the adoption of cheap steel and the useful mechanical auxiliaries, largely perfected by the American, Alexander L. Holley, which enables a modern plant with two converters to send forth a continuous procession of ingots, without halt, day and night (*see* BESSEMER, SIR HENRY; BESSEMER STEEL).

Converter House.—(*See* fig. 2.) Molten pig iron comes from the blast furnaces in ladle cars, and an overhead crane lifts the ladles and pours the contents into the mixer. By joining a reservoir of several hundred tons of metal wide variations in chemical

composition in a single cast are lost by dilution. A reservoir of uniform and promptly available raw material is thus established. Uniformity and continuity are foundations of rapid production of Bessemer steel; neither of these results when converting metal direct from the blast furnace or remelted pig iron from the cupola—although the latter sources may be used in emergency. At the proper time a ladle of iron, 10 to 25 tons depending upon the size of the converter, is poured from the mixer; it tilts by rolling on a circular track under positive control of a screw mechanism or hydraulic ram. A small locomotive pushes this full ladle car to the converter house, and by means of a launder the contents are run into the hot converter, with mouth tilted over to receive the charge. The blast is turned on, the converter tilted up to vertical position, and the blow is on (*see* Plate I).

Conversion Process.—The converter itself (*q.v.*) is a cylindrical steel pot perhaps 10 ft. diameter by 20 ft. high mounted on elevated trunnions and geared into a rack and pinion so it can be turned completely over. It is lined a foot thick with a refractory mixture. The bottom bricks are perforated by many small openings, tuyères, through which air is sprayed into the metal at high enough pressure to keep it from trickling down into the wind box attached to the bottom of the converter shell, yet not so high as to throw too many splashings out the open mouth. Oxygen in the air blast burns the pig iron it first strikes. This product of reaction may be represented by FeO , and it is swiftly distributed throughout the churning mass. At the temperature of operation silicon and manganese atoms have a greater affinity for oxygen than iron has, so these two reactions occur:

These oxides are insoluble in metal and accumulate into droplets of slag—a mixture of iron oxide, manganese oxide and silica. When the metals silicon, manganese and iron combine with oxygen, or burn, much heat is released—enough to heat the incoming air and escaping nitrogen, to provide for radiation losses, and to increase the temperature of the remaining metal and slag so it is always quite liquid. During this early stage of the blow the red hot nitrogen coming from the mouth glows faintly. Gradually the carbon begins to burn, thus:

A roaring boil then takes place in the vessel; the carbon monoxide burns in a big, yellow, luminous flame at the converter mouth, and countless flying sparks of metal and slag add to the spectacle.

In only a few minutes the carbon is gone; the flame flickers, and suddenly contracts. This is the signal for turning the vessel over on its side, and stopping the blast. Inside the hot converter is now a seething mass of fluid iron, practically free of silicon, manganese and carbon, covered with a thin layer of slag. The metal, however, contains much gas in solution and if cast immediately would solidify in a spongy mass. Consequently some cupola-melted spiegel—a pure pig iron containing 20% manganese—is run into the converter. A violent reaction ensues, wherein the steel is freed of oxygen by combination with the excess of manganese and carbon in the spiegel. The converter then tilts further over, discharging its contents into a waiting ladle. The blow has taken perhaps 12 min.; no greater time is necessary to add the spiegel, pour out the steel, turn the converter upside down to discharge any loose slag chunks, and back up to receive another ladle of liquid pig iron. A second converter alongside will be blowing while the first is dumping. In fact the whole equipment of the converter department is co-ordinated for a complete cycle every 12 to 15 min., and is built of the most rugged proportions, so delays from breakdowns will seldom occur.

Converter Lining.—The violent reactions at high temperatures cause considerable scour on the lining of the vessel; especially the tuyère brick at the bottom must be replaced after 20 to 25 blows. Holley is responsible for the plan of sectionalizing the converter shell; when a new bottom is required a car carrying a stout jack is placed under the upright converter, a series of bolts unloosed, and the jack lowered away, carrying with it the entire bottom part of the shell. This car is immediately replaced by another carrying a newly made bottom, already warm, ready for lifting and bolting into place. It is therefore unnecessary to leave a shell in the stand while it cools and the lining is repaired, dried and reheated—a matter of several days—but these sectional lining operations are done in a separate department and replacement of bottom or mouth portion requires less than 30 min. In American practice the lining material is a highly siliceous rock, ground with a little fire clay, moistened and tamped in place with pneumatic rammers. Such a lining is known as an acid lining, and steel made therein is called acid Bessemer steel.

Pig Iron Used.—Since the reactions described above leave untouched any sulphur or phosphorus, it is necessary that the pig iron entering the converter be quite low in these two elements. Furthermore silicon is limited by the rate of driving. It is the chief heat-producing element; if silicon in the pig is high the converter shell and its contents get superheated during continuous blowings and must be cooled either by dropping a quantity of cold scrap into the shell, by blowing steam in with the blast (which dissociates and absorbs heat), or by delays for radiation. On the other hand if the converter with a new bottom is a little cold, it is tilted partly over so some blast does not penetrate the iron, but burns the CO to CO₂ thus liberating more heat within the vessel. Maximum production may be had by blowing a pig iron with higher silicon and lower carbon; reducing the blowing time by charging mill scale or ore at the beginning of the blow; and charging scrap to absorb the excess heat generated. But in general the pig iron used for acid Bessemer practice, and the product therefrom will be about as follows:

	Carbon	Silicon	Sulphur	Phosphorus	Manganese
Pig iron	3½ to 4	1 to 1½	0.05	0.09	½ to 1½
Full blown	0.03	0.01	0.05	0.10	0.03
With spiegel . . .	0.40	0.10	0.06	0.10	0.90

Growth of Uses.—Obviously such material as represented by the last analysis is immeasurably superior to wrought iron for railroad rails. The carbon content is responsible for hardness, wear resistance and strength which wrought iron could never

acquire. Furthermore, the amount of carbon, and the corresponding degree of improvement in properties, is under control, for it is only necessary to place some charcoal in the steel ladle to make a higher carbon steel, or to use a spiegel or a ferro-manganese containing higher manganese and lower carbon when a milder or softer steel is desired. It is not surprising, then, that when the process was finally established on a producing basis in Bessemer's own plant in Sheffield, the product was rapidly absorbed for rails and tires. In 1863 there were 110,000 tons produced; in 1888 Bessemer steel reached its peak of production in Great Britain of 1,700,000 tons. Puddling had meanwhile declined; 70% of British pig iron went into wrought iron in 1883; only 5% in 1887. A similar story may be told of America. In 1867 460,000 tons of iron rails were made and sold for \$83 per ton; that same year 2,550 tons of Bessemer steel rails were produced and some purchasers paid \$170 a ton for them. By 1884, however, the last iron rails were made, steel had replaced them to an annual production of 1,500,000 tons a year, and the selling price was \$32 per ton.

THOMAS-GILCHRIST DISCOVERY

Control of Phosphorus.—This so-called acid process demands low-phosphorus ores and pig, and such material in Europe is relatively scarce and costly. Early efforts to remove phosphorus in the converter failed. Arguing from an analogy in the puddling furnace, where a slag rich in iron oxide will carry off phosphorus oxides, it was thought that if the converter blast was carried on after the carbon was gone, much iron oxide would go to the slag, and it would then be in a condition to absorb the phosphorus. When this was tried, however, the iron wasted away, ate into and ruined the lining, but unfortunately had no effect on the phosphorus. Not until 1876 did the Englishmen, Sidney G. Thomas and Percy G. Gilchrist discover that if the converter were lined with a basic material like burned limestone, dolomite or magnesite, and if burned lime were charged with the pig iron, then a basic slag would form and be maintained in such condition that it would absorb and hold phosphorus oxides produced during the blow. These are the essential features of the basic Bessemer process now so widely used on the Continent for the production of so-called Thomas steel.

Basic Bessemer Process.—A modern basic plant is arranged much like its counterpart using the acid process. Converter shells are lined with different materials. Dolomite is freshly calcined in a cupola, ground with hot dehydrated tar, and the sticky mass tamped between the shell and a centre form. The perforated bottoms are lined two ft. thick, but even so they must be replaced daily.

In its modern development a heat of Thomas steel is made thus: Into a 10-ton converter 1½ tons of freshly burned lime are charged and then 10 tons of pig iron. The blast is turned on, the converter tipped up, and the blow proceeds exactly like an acid heat already described, but it continues after the carbon flame drops. In this last stage of the blow the following reaction occurs:

and the phosphorus joins with excess lime in the slag to form a calcium phosphate. There is no flame to indicate occurrences in the converter during this period. The duration of the after blow is judged from a knowledge of the phosphorus contained in the original pig iron. When the process is thought to be complete, the converter is tipped to its side, the blast turned off, and a spoonful of metal cast into an iron mould. This test ingot is chilled, hammered into a bar, and nicked, bent and broken. If the metal is brittle and coarsely crystalline, the air blast is resumed for a few seconds, and another test taken, and repeated until the metal is tough and fine grained. This finishes the blow. Next the slag must be skimmed off as closely as possible, because phosphorus has a trick of returning to the metal on slight pretext; then the spiegel or other recarburizer and degasifier is added, and the steel poured into the ladle. About the only additional equipment in the converter house needed beyond that found in

an acid Bessemer plant is some handy means of caring for the large volume of slag produced. This slag, by the way, is ground and sold as fertilizer, it contains up to 20% of soluble phosphoric acid.

Thomas Steel.—In this Thomas-Gilchrist process, the pig iron must have relatively low silicon to limit the amount of slag formed. Phosphorus is the principal heat producing element, and it may be as high as 3%. It is doubly essential that a mixer be used to store pig iron, in order that phosphorus may never show wide fluctuations in analysis, heat to heat. Percentages in average analyses are as follows:

	Carbon	Silicon	Sulphur	Phosphorus	Manganese
Basic pig	3½ to 4	0.5 to 1	0.05	2 to 2½	1 to 1½
Thomas steel	0.10 to 0.60	0.20	0.05	0.03 to 0.10	0.30 to 0.50

The process was introduced in Germany in 1879, and at the present time is used to refine the bulk of the pig iron produced from the Lorraine deposits. Approximately 15,700,000 tons of Thomas steel were made in France, Germany, Luxemburg and Belgium in 1926. It provides satisfactory material for all classes of tonnage steels used on the Continent, such as bars, boiler plate, pipe, structural steel and rails. But despite the fact that the Thomas-Gilchrist process was proposed to solve the problem of high phosphorus British ores, Thomas steel is not popular among English engineers, and hardly any of it is now made in England. This is probably due to the fact that the home ores do not smelt into a low-silicon high-phosphorus pig iron necessary for the economical operation of a basic converter, and further that the basic open-hearth furnace has meanwhile been developed to refine such phosphoric pig irons as are made.

OPEN-HEARTH PROCESS

As soon as the Bessemer process attained a production stage it was found that the mild steels intermediate in carbon content, strength and ductility between carbon-free wrought iron on the one hand and high carbon crucible steel on the other, were most useful materials for machinery and engineering structures. These mild steels were really new materials, never before procurable in quantity, and inventors attempted to make them in ways which would not infringe the Bessemer patents. An insuperable difficulty was the inability of any furnace, even when burning high volatile coal under forced draft, to melt them. As in the puddling process, when the refining reached a certain stage, the metal became a pasty sponge. This obstacle was met by Sir William Siemens, who resurrected a forgotten proposal to regenerate some of the waste heat (see REGENERATIVE FURNACE). He passed the smoke through brick chequer-work; after the passages had thus been highly heated, air for combustion of the coal was drawn through the chamber. This pre-heated air had the effect of increasing the flame temperature materially. Using a furnace with such a device Emile and Pierre Martin made steel at Sireuil, France in 1864, by melting a good grade of pig iron, then adding some selected wrought iron scrap which alloyed with the pig iron, continuing these additions until the carbon content was reduced to the desired percentage mainly by dilution (the Martin pig and scrap process). William Siemens (*q.v.*) and his brother Friedrich found it necessary to erect an experimental furnace plant in Birmingham to develop the application of their ideas in the steel industry. By 1868 the principal features of the modern open-hearth process were there developed; namely, gaseous fuel, regenerative chequer-work for pre-heating both air and gas, a thin furnace roof of silica brick and the method of refining pig iron by ore or iron oxide (the Siemens pig and ore process). These entire furnaces, hearth, side-walls and roof were made of highly siliceous refractories; the only slags which would not corrode these contain an excess of silica—so-called acid slags. Not until Thomas had shown how to remove phosphorus by a basic, high lime, slag in the basic lined converter did it occur to anyone to make an open-hearth furnace

with hearth and side walls of sintered dolomite—lime and magnesia oxide—and to refine the steel under a high lime slag. J. H. Darby built the first of these basic open-hearth furnaces at Brymbo, Wales in 1884. The most available ores in both England and America smelt into pig iron well suited for such basic open-hearth refining; furthermore the product is distinctly superior in quality to Bessemer steel. Consequently at the present time the latter is used in America for the production of low-carbon steels like ordinary steel sheet, pipe, wire, bars and hoops. Basic open-hearth steel, however, makes boiler and ship plate, structural steel, rails and all the higher carbon machine steels, such as shafting and forging billets. Production by processes is shown in the following table—it will be observed that the basic open hearth is competing with the basic converter even on the Continent.

	United Kingdom 1925	United States 1926	France 1926	Germany 1926
Acid converter	447,200	6,934,568	60,699	..
Basic converter	28,300	..	5,812,264	5,452,223
Acid open hearth	1,968,600	1,038,664	..	116,126
Basic open hearth	4,744,000	39,653,315	2,458,296	6,484,467
Electric	64,100	651,723	83,554	..
Crucible and others	133,200	15,493	15,189	104,564

Furnace Auxiliaries.—The essential furnace is often dwarfed by the auxiliaries found necessary for rapid and economical production. (See fig. 3; also REGENERATIVE FURNACE.)

In the first place adequate fuel must be provided; consequently alongside is another building containing gas producers (*q.v.*) of the continuous type. A series of such producers in operation discharge gas into one main pipe from which it is drawn to the furnaces as needed. The producer house must have therefore adequate coal handling machinery; a plant with 10 60-ton furnaces would use 400 tons of coal a day, with means for hauling or sluicing the ashes away, and boilers for raising steam to blow into the producers. Gas producers are usually found as standby equipment, even where other fuels are used, such as blast furnace gas, by product coke oven gas, natural gas, tar, oil and powdered coal. Next a stock of adequate raw material is necessary. If open-hearth and blast furnaces are within the same fence, melted pig iron (hot metal) will be used. That requires a mixer for intermediate storage. Otherwise an ample stock of iron in pigs is required. Furthermore a big tonnage of steel scrap of various kinds is used—the proportions of pig iron and scrap charged into steel making furnaces now depends solely upon the relative availability and cost of these two materials. Scrap must be segregated as to nature and approximate analysis; big shears and drop balls (skull crackers) are necessary for cutting and breaking unwieldy pieces; travelling cranes and lifting magnets are installed for economical handling of this material. Bins and stockpiles must be provided for the various special metals used for alloying or degasifying the hot steel, for the limestone, fluorspar and other fluxes, for the silica, chrome, magnesite and other fire brick to repair the furnace, for the dolomite or silica rock used for making the bottoms. In basic open-hearth plants an auxiliary building is necessary for grinding, calcining and storing the dolomite continually needed for repairing the furnace bottom and side walls (banks). Spiegeleisen, if used for a de-oxidizer, must be melted in a cupola or electric furnace.

Means must be provided for introducing the fuel into the furnace, and reversing the flow of flame at frequent intervals. This requires proper valves in the flues, with an appropriate series of interlocking operating devices. Latter-day trends in furnace design call for much shorter and more direct flues than shown in the cross sectional view, and the use of water cooled gate valves offering no obstruction to gas flow when open. Waste heat boilers are also quite frequently placed between regenerators and chimney, together with fans to pull the hot gases through them. A most interesting device is installed to charge solid material through the doors into the furnace itself. By this means long delays between heats to refill the furnace are avoided, together

METALLOGRAPHY: ETCHING AND MICROSCOPIC EXAMINATION OF STEEL

1. Sorbite, showing structural fineness (50 diam.). Lightly etched
2. High carbon steel; carbon content 1.15% (500 diam.). Etched
3. Quenched high-speed steel; austenite, containing small grains of carbide which separates from the metal on cooling (500 diam.). Etched
4. High-speed steel, properly drawn at 600° C to give best cutting properties; martensite changing to troostite; white grains are excess carbide. (500 diam.)
5. Steel sheet with grains flattened by moderate cold rolling (500 diam.). Etched
6. Annealed medium hard steel containing 0.60% carbon (100 diam.). Etched
7. Sulphur print from section along centre of steel bar, showing high sulphur core. Sulphur in bar reacts with silver compound on acidulated paper
8. Cross section of deeply etched steel bars showing uniform structure in bar above, segregated centre in bar below
9. Wrought iron, section parallel to rolling direction (500 diam.). Etched
10. Banding or flow lines due to high phosphorus regions in base of shrapnel shell forging (1½ size). Etched with ammonium persulphate
11. Section of high carbon steel wire, cold drawn to limit (350 diam.). Etched
12. Structural steel containing 0.25% carbon, showing banding of constituents (75 diam.). Etched
13. Annealed pearlite containing 0.90% of carbon (250 diam.). Etched
14. Troostite (dark areas) in martensite (light crystals) (200 diam.). Etched
15. Nickel steel forging (3%) before heat treatment (7 diam.). Etched
16. Nickel steel ingot (3%) showing coarse grain structure as compared with fig. 15 (7 diam.). Etched
17. Ingot iron, lightly etched. Pure ferrite with small non-metallic inclusions (100 diam.)

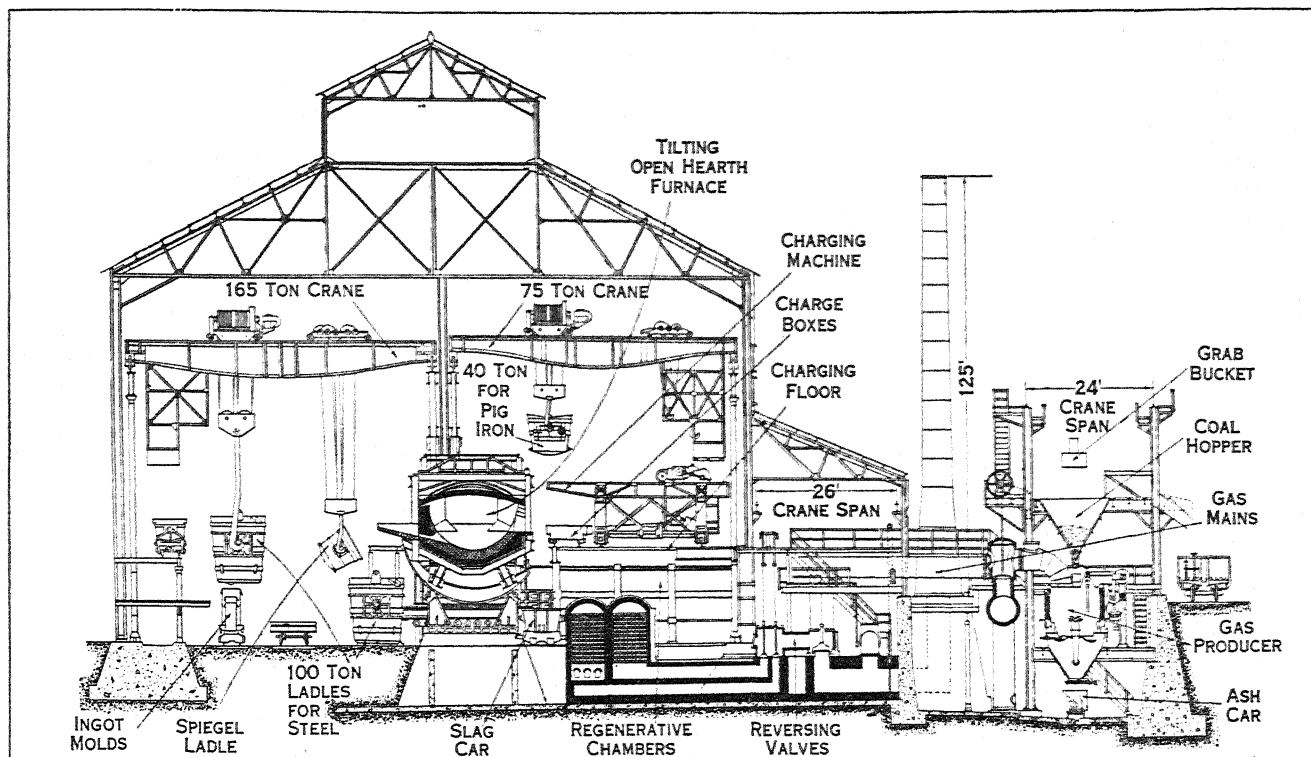

FIG. 3.—GENERAL DIAGRAM OF AN OPEN-HEARTH PLANT SHOWING GAS PRODUCERS AND CRANES FOR HANDLING METAL

with much exhausting labour. All solid materials are now loaded into charging boxes, cast steel trays about 24 in. wide and deep and about 4 ft. long, thus holding at least a ton of the bulkiest steel scrap. A complete charge for a furnace is assembled into 40 or 50 such boxes, placed on a train of small flat cars, and moved to a track running close to the furnace doors. On a wide gauge track alongside, the charging machine operates. Its ram engages an end socket on the box and is locked in. The ram then lifts the loaded box off the car, moves it forward through the open door into the furnace, slews it to either side and tips it upside down, discharging its contents in the correct place. These motions are then repeated in the reverse order. When the empty box is on the car, the charging machine moves sideways, taking with it the entire train of loaded cars until the next full box is spotted directly in front of the proper door. This is then picked up, thrust into the furnace, and dumped. In this manner a 60-ton furnace can be loaded in less than an hour. Equipment must also be installed to pour the finished steel into ingot moulds, but this is an operation which, both in the principles involved, and in practice, is similar to casting a Bessemer heat, and will be described later.

Open-hearth Steel from Cold Metal.—The basic open-hearth process (1928) makes by far the most steel. Many steel-making furnaces are distant from blast furnaces, so they operate entirely on cold stock, and as noted, any proportion of pig and scrap may be charged, as economics require. This process is commonly practiced in a 50-ton furnace and its elementary chemistry are here briefly explained. After a furnace has been tapped and the bottom and banks repaired charging is begun. Plate scrap, if available, is spread out to protect the bottom, followed by from $2\frac{1}{2}$ to 10 tons of limestone, depending upon the impurities to be removed from the pig and scrap. The furnace is then filled as full as possible, with scrap, pig iron and some iron ore; the doors are then closed, the flame given an excess of air and melting begins; as the mass melts and settles, the balance of the cold metal is added. Melting pig iron will trickle down over the white hot steel, still solid. Silicon and manganese in the pig iron droplets oxidize by the excess oxygen in the furnace atmosphere, and join with the iron oxide forming on the white hot steel and some of the lime on the bottom or furnace wall forming

a slag. In four to five hours the molten metal is virtually free from silicon, and much manganese has also gone into the slag. Vigorous stirring is necessary as chemical reactions only occur at the surfaces where metal and slag are in mutual contact. This is effected principally by gases rising from the limestone, and some two hours after the metal is fluid it continues to break up, thus

The gas coming to the surface in big bubbles causes a characteristic boil. The lime also floats up, joining the slag as a base, not only releasing some of the iron oxide contained therein for refining reactions, such as

but also maintaining the basic slag necessary to dissolve and hold this phosphorus oxide. When the lime is all up further boiling in the bath is due to the chemical reaction between iron oxide and carbon, which has been going on continually but its mechanical effect somewhat overshadowed by the lime boil

The iron oxide is dissolved by the metal from the slag. Bubbles of carbon monoxide gas evolved continue to keep the metal and slag in motion. The active refining reagent in the open-hearth furnace is the same as in the Bessemer and the earlier refining processes, namely iron oxide, but its origin is different. In the open-hearth process iron oxide is formed by oxidation of the steel during melting, picked up from the rusty scrap, and is added as desired to the slag in the form of ore. During the late refining period, the furnaceman frequently takes a spoonful of metal from the bath, pours test ingots and breaks them, judging from the fracture the content in phosphorus and carbon. It is necessary to regulate the proceedings so that phosphorus in the metal shall be down to the desired minimum some time before the carbon is down. This relative elimination can be controlled by adjusting the temperature, reversing the flow of gases more frequently increases the heat, changing the slag by adding either lime or ore, increasing its fluidity by adding fluorspar (CaF_2) or increasing the carbon by adding some low-phosphorus pig iron. In about three hours the carbon boil should subside, the bath should be low in phosphorus,

and the slag essentially a high lime silicate—to hold the phosphorus; the furnace is then driven hard to increase the metal's temperature sufficiently for casting. The slag and the metal have been slowly losing iron oxide and carbon respectively by mutual interaction, and the metal gives up considerable gas held in solution. When the word is given, the furnace crew thrusts a long heavy bar through an opening in the centre door, across the furnace into the bath; several battering-ram thrusts break through the plugged tap hole, and white-hot metal rushes down the spout into a ladle set beneath. This ladle is just large enough to hold the steel; slag which follows after overflows into a pit or slag ladle alongside.

As in the Bessemer process, it is necessary to add manganese to this metal in order that it may not evolve gas when solidifying and form a spongy ingot. This is done by placing some 80% manganese alloy into the ladle before tapping; any deficiency in carbon is made up by broken coke or charcoal. These are absorbed by the superheated steel coming from the furnace, and distribute themselves throughout the entire mass before the steel is cast. The pig iron used should be free from sand and low in silicon, in order to limit the total volume of slag; its phosphorus content is considerably lower than in the basic Bessemer, else some will remain after the carbon boil. Manganese of 1 to 2% helps burn out some sulphur during melting, and quiets the steel during the finishing stage.

VARIATIONS IN PROCESS

Use of Molten Pig.—Various methods have been proposed to speed these actions, which take in all about 12 hours. By ideas suggested to Ambrose Monell at Pittsburgh in 1900, 75% or more of melted pig iron is used and a heat completed in nine hours. The process is as follows:

Into a 50-ton furnace are charged 5 tons of limestone, twice as much iron oxide and 10 tons of scrap. After about two hours the ore is a pasty mass, a little of the lighter steel has melted, and forty tons of melted pig iron are rapidly poured into the furnace. Chemical reactions between iron oxide slag, silicon, manganese, phosphorus and carbon in the pig iron start immediately, and go forward simultaneously but at different rates. A slag containing silica and manganese oxide forms without delay; iron ore and calcined lime work up from the bottom and enter the slag. As more and more of the iron and lime comes up, the slag becomes more basic, *i.e.*, the proportion of CaO and FeO to SiO₂ increases, until it can absorb and hold the phosphoric oxide being formed by the familiar reaction with iron oxide. Slag also becomes more viscous with increasing lime; the carbon escaping in gas bubbles causes it to froth, swell to great bulk and overflow through an opening above and alongside the tap hole, thus carrying out of the furnace most of the phosphorus, manganese and iron ore. In about two hours the frothing dies down, because the carbon content has been reduced, both by continued oxidation and by dilution with the now melted scrap. The increased heat, however, causes the limestone still on the bottom to break up into CaO and CO₂, the gas bubbles cause a vigorous lime boil, the lime replaces iron oxide in the slag, allowing it to re-enter metal for the slower reduction of the residual carbon. Final adjustment of slag, temperature and composition during refining, finishing, and tapping stages is no different than when using cold pig.

Continuous Steel Making.—Benjamin Talbot first built furnaces for continuous production of steel at Pencoyd, Pa., in 1899. They are of large capacity—200 to 300 tons of metal—and are mounted like a mixer on trunnions; they can be tilted forward and slag skimmed or metal poured through a spout, normally far above the liquid bath. In operation, a full charge of metal is refined in the usual way, when ready to pour, the slag is drawn off first, and then about one-third of the steel is poured into waiting ladles. A new and highly active slag is then made up by charging limestone with an excess of iron oxide. When heated sufficiently, melted pig iron is poured in to refill the furnace. Refining is very rapid, and casts of completed steel can be made at 6- to 8-hour intervals. By virtue of the ability to remove slag easily when its utility has gone, a tilting furnace is very useful

for refining steels to various compositions, from a charge of molten pig iron without scrap.

Duplex Processes.—Other means of speeding the rather deliberate open-hearth reactions are used extensively, perhaps the most important being a combination of acid Bessemer and basic open hearth. This enables the steel-makers to start with a high sulphur ore, smelting it to a high silicon, low sulphur pig iron, blowing the silicon and carbon out in a converter, and transferring the molten steel to a large tilting furnace where the phosphorus, oxide and gases are eliminated. In American practice 250-ton tilting furnaces are used; 50 tons of molten steel are reserved in the hearth, a highly basic combination of ore and lime is charged, melted, and about 150 tons of blown metal poured in. When the temperature and slag are correctly adjusted, a ladle of basic pig iron from a mixer is charged. A strong carbon boil ensues immediately, and the slag foams up and overflows, carrying much of the phosphorus and some sulphur. When the first reaction quiets down, a second ladle of pig iron causes it to resume, and drives out the rest of the phosphorus. The slag is then skimmed off, enough pig iron is added to bring the carbon to the desired percentage, and the metal finished and superheated for pouring. From such a furnace, 200 tons of steel can be taken every 3 or 4 hours. Other variations in this practice have enabled the furnaceman to finish heats in even shorter time.

Duplex processes of the sort described but using two open-hearth furnaces originated in Germany and are used for irons somewhat too low in phosphorus for the basic converter. In the first furnace, run at a rather low temperature, the phosphorus and silicon are eliminated into a lime slag rich enough for use as a fertilizer. The furnace is tapped, the slag separated, and the metal introduced into another and hotter furnace, wherein awaits a proper slag for rapid carbon elimination. This is called the Bertrand-Thiel process; the Hoesch modification recharges the partly purified metal back into the furnace from which it has just been drained. Super-refining molten basic steel in an electric furnace is another variety of duplexing which has been practised in America; by eliminating sulphur and oxidizing particles, most excellent steel is made.

Acid Steel.—Furnaces made with siliceous bottoms and banks, the descendants of the original open-hearth furnaces, still exist in considerable number. They make steel under slags which are essentially mixtures of iron, manganese and silicon oxides, having well over 50% of the latter, and are so quite acid in nature. Such acid steel has an enviable reputation for quality, but since the furnace reactions remove neither sulphur nor phosphorus, the raw materials and fuel must be selected with much more care; low silicon and high manganese are also desirable.

Pig and scrap, as available, are charged cold into the furnace, which has a higher roof to withstand the higher refining temperature; during melting, nine-tenths of the manganese and silicon are oxidized, and join with the rust and burned iron to form a slag. Carbon is eliminated slowly by reaction with the iron oxide in the slag; a little ore is added some two hours after the charge is well melted to keep this reaction going until the residual carbon in the metal equals that required in the steel being made. Temperature is driven higher and higher. Toward the end of this refining period—which may require seven hours—some manganese and silicon re-enters the metal, reduced from the slag by obscure chemical reactions. They are very effective in removing oxygen and other dissolved gases. At the end the metal is slowly losing carbon but gaining manganese and silicon. However, manganese is still too low for most steel specifications, so an appropriate amount of ferro-manganese is added some 20 min. before tapping. A complete cycle of operations may require up to 16 hours when making steels for ordnance. The superiority of acid open-hearth steel is due to the better grade of raw material used, the small amount of slag formed (perhaps 7% of the metal), the more deliberate working of the heat enabling the furnaceman to bring his metal to the right analysis without making large additions of alloys, and the ability to eliminate gases and non-metallic impurities from a super-heated fluid metal while it is still in the furnace.

ELECTRIC STEEL

Electric furnaces (*q.v.*) are usually round in plan, with low side walls, flat domed roofs and invert bottoms, built inside a stout bowl of steel plates, which in turn is attached to some tilting device. Side walls are pierced by one or more doors and a pouring spout. The side wall and bottom linings may be either acid—silica brick and fused siliceous material—or basic magnesite. (The acid furnace is confined generally to small installations in foundries, and is merely a melting and super-heating device, since the unique carbide slags to be described later cannot be formed inside a siliceous lining.) Roofs are of silica brick, and are pierced for carbon or graphite electrodes, one for each phase of current, of proper size to carry the electricity without undue resistance. Furnace capacities range from $\frac{1}{2}$ ton for small foundries, to 50 tons for super-refining liquid steel. Size is limited by the size of electrodes available; of the latter, a carbon 40 in. in diameter is the maximum; a 7-ton furnace would be about 12 ft. in outer diameter, with 13 in. side walls, and hearth $5\frac{1}{2}$ ft. inside height. In operation, the electrodes are automatically adjusted so the lower ends are constantly a correct distance above the slag. Electric currents of large amperage arc cross this gap, flow through the slag to the metal and there neutralize equal currents of opposite phase led in through the other electrodes. Heat is generated principally by the resistance offered by the air gap and the slag layer to the flow of this current. The electrodes are consumed gradually, combining with oxygen of the air within the furnace, producing a carbon monoxide atmosphere, desirable for steel refining.

Advantages of Electric Heat.—No virtue is given to electric steel by the electricity. It is merely a convenient source of heat, under close control. The advantages of electric furnaces for steel making are: (a) the ability to generate a high temperature and thus cause certain desirable reactions to occur; (b) the virtual absence of products of combustion and their undesirable compounds of carbon, hydrogen, sulphur and oxygen; (c) the ability to remove a slag and make up new ones, thus controlling refining reactions; (d) the metal is hotter than the refractory, a prime advantage in cost over crucible melting; (e) less slagging of alloying elements, thus making for economy and control of chemical composition within narrow limits. Such advantages are illustrated in the process of super-refining molten metal from the open-hearth furnace; in such operations the basic electric furnace is a unit of a duplex or even a triplex process—the pig iron may be de-siliconized in an acid converter, de-phosphorized in a basic open hearth, and de-oxidized and de-sulphurized in a basic electric furnace.

Super-refining Molten Steel.—Open-hearth steel is taken from the furnace when the carbon has dropped to the required figure, and a little ferro-silicon or aluminium added to the ladle to prevent further decarbonization during the transfer. In such condition the phosphorus and silicon are both very low—0.010% or less—while the sulphur depends upon the purity of the metal at the beginning, none being lost in the process so far. In fact the metal picks up a little from the furnace gases. If a nickel steel is to be made, the correct amount of shot nickel is added when this liquid metal is poured into the electric furnace. After the current has played long enough to remelt any crust of metal which may have chilled, a highly basic white slag is made up and melted, consisting mostly of burned lime with only enough silica sand and fluorspar to give it the proper fluidity. In quantity this would amount to about 3% of the metal. An excess of ground carbon is then shovelled in, the furnace closed, left under current for from $1\frac{1}{2}$ to 5 hours, depending upon the quality of steel required, and the doors opened only for sampling or adjusting the slag. Under these conditions of a reducing atmosphere, a high lime slag, and intense heat, calcium carbide is formed by reaction between the lime and crushed carbon

Slag samples quenched in water give off much acetylene (*q.v.*) easily distinguished by its characteristic odour. Such a carbide slag not only reduces oxygen in the steel but is capable of abstract-

ing the sulphur. The reaction for the latter may be something like this:

By this means ordinary open-hearth charges which usually melt to 0.05% sulphur are reduced to one-half that amount in a four-hour cycle, while selected charges melting to 0.015% sulphur can be driven to less than 0.005% in a heat taking 8 hours. It will be observed from this reaction that some manganese is necessary. This will be residual in the open-hearth metal, for it has been found that if say 1% manganese is in the original pig iron, the resulting steel, containing 0.30 to 0.50 manganese will be of much better quality, sounder and cleaner, than from a low-manganese charge.

When the soapy slag stops its slight foaming, it is a sign that desulphurizing and deoxidizing is about completed, and the various alloys necessary to make the required analysis are added at intervals in order of their oxidizing power, namely, ferro-silicon first, then ferro-manganese, ferro-chromium, and finally ferro-vanadium. Carbon is picked up from the carbide slag and from these alloys. After all these alloys are melted and diffused the current is shut off and the metal lies quiet for 30 min. or more, to allow entrapped particles of slag to arise and the superheated metal to cool and liberate dissolved carbon monoxide gas. Slag is then most carefully skimmed, and the steel poured into a ladle which may contain a little carbon, ferro-silicon and ferro-zirconium. After 30 min. further cooling the metal is teemed into warm, scrupulously clean moulds with hot tops. A sectioned ingot will show no cavities as large as a pin head.

Quality of Deoxidized Steel.—Quality of such deoxidized and desulphurized steels rests in a number of characteristics, some not capable of evaluation, such as better response to heat treatment, less non-metallic inclusions, as shown under the microscope and after deep pickling in strong acid. A better gauge is the transverse properties. If a well made heat of basic open hearth steel is forged into a big gun, tension test pieces cut out of this forging will show high ductility if the piece is cut in a direction parallel to the axis of the gun. On the other hand if these test pieces are cut tangentially to the bore, the ultimate strength is satisfactory but the ductility is not much more than half the longitudinal piece. Unfortunately this transverse weakness is in the very direction which must bear the heaviest stress when the gun is fired. An accepted explanation of this phenomenon is that the work of forging ranges the non-metallic impurities into layers parallel to the faces of compression, and interrupts the metallic continuity. Obviously, the cleaner the steel the less would be the transverse weakness. For that reason important forgings, such as hollow tubes to resist internal pressure, are commonly made of acid open-hearth steel. Super-refined basic electric steel is even better, as shown by the following typical tests from big gun forgings of nickel steel:

	Longitudinal	Tangential
Ultimate strength, lb. per sq. in.	110,000	110,000
Elastic limit, lb. per sq. in.	58,000	58,000
Elongation in 2 in., %	56	42
Contraction in area, %	24	21

Melting Cold Scrap.—By far the larger number of electric furnaces are of small capacity for melting cold scrap. While it is possible to refine impure pig iron in either the acid or basic electric furnace, it has been generally found more economical to start with clean, relatively heavy, high manganese scrap and melt without additions of iron ore. In a basic furnace considerable lime would be charged into the empty furnace; melting is done under the heaviest power input practicable. The slag formed on the steel is always black from the rust and oxide formed during melting. This slag is removed as soon as the charge is melted, and some ground carbon electrode butts are shovelled into the furnace and flapped under the metal. As the carbon dissolves, it first tends to deoxidize the steel

and the carbon monoxide gas comes up in bubbles. Some surplus carbon helps bring the carbon to the required analysis. Then a

white or carbide slag is made up, and the refining and alloying is done with current of lower voltage and as described in detail above. Whereas a large furnace for deoxidizing clean liquid open-hearth steel can turn out a heat of steel in $2\frac{1}{2}$ hours with a current consumption of 150 kva. per ton, a heat from cold metal in a small furnace requires 6 to 8 hours and consumes about 650 kva. of electricity per ton of steel. A typical cycle would be:

	Hours
Repairs and charging	1
Melting	2
Skim and make up white slag	$\frac{1}{2}$
Deoxidation	2
Soaking	1
Kill, cool and pour	$\frac{1}{2}$
Total	7

If the carbon is a little low, washed metal (a pure pig iron) is added after the deoxidation period. It is also customary to add a little ferro-silicon about 30 min. before pouring.

Statistics show that electric steel has practically supplanted crucible steel in America, but has not been so successful in Great Britain. Italy being rich in water power, but very poor in fuel, has about 200 electric furnaces with annual capacity of one million tons, but nearly all of them produce tonnage steels. Much controversy exists as to the relative quality produced by the two processes. It is probably true that there is little difference when selected raw material is charged, an expert furnaceman is employed, and equally careful pouring, forging and annealing practice is adhered to—in other words, when equal care is given to the respective heats. But steel from either process can be disappointing when conditions get out of control. The crucible is more convenient for smaller casts of plain high-carbon steels; the electric is more convenient for heavy ingots of lower carbon, higher alloy steels.

INGOTS

Gases in Liquid Metal.—Early attempts to make steel in England by Bessemer's process were failures because the metal when poured into ingot moulds boiled over and the remaining portion when solid would be full of blow-holes, like a Swiss cheese. Robert Mushet noted that the only apparent difference between sound ingots and the spongy ones was that the former were made of high-manganese pig iron and a little manganese remained in the steel; consequently he proposed adding some of the metal after the blow. Thus originated the practice already described of adding spiegel or ferro-manganese to heats of steel made by any of the Bessemer or open-hearth modifications. Superheated liquid steel absorbs gases from the atmosphere or oxygen from the slag. This gas is only slowly evolved as the steel cools off, but it boils out vigorously just at the freezing point. In the crucible and acid open-hearth process much of this oxygen is eliminated by holding the melted metal quietly in the furnace until reactions between the siliceous linings and the metal allow the latter to absorb some silicon which in turn is very effective in removing dissolved or combined oxygen existing in the steel, and causing it to solidify quietly without effervescing, which imparts superior physical properties. This time-consuming reaction is avoided when producing cheaper steels in great tonnages by adding the degasifiers to the steel in the ladle, or even as it is poured into the ingot. Melted spiegel-eisen is used for medium carbon Bessemer steels. Since spiegel ordinarily contains 20% manganese and 5% carbon, it will be observed that sufficient manganese to quiet the steel will also introduce considerable carbon. Should this be too much for the desired grade of steel, ferro-manganese is used instead. Since a relatively small amount of this is required small pieces are placed in the ladle, and melted by the intruding steel; if the metal on casting still seems too effervescent, a few aluminium shot are thrown into each ingot. The principal effect of each of these metals is to rob harmful iron oxide existing in the steel of its oxygen, thereby transferring it to MnO , SiO_2 or Al_2O_3 as the case may be. These oxides are highly insoluble in metal, and tend to accumulate into slag particles and float; but there is little opportunity for

such elimination when the reactions occur in the ladle or ingot mould.

Teeming Practice.—It is usual practice to transfer steel from converter or open-hearth to ladle somewhat too hot to pour; also to use a ladle of correct size so most of the slag overflows. Ladles, therefore, contain from 5 to 200 tons of steel, depending on the furnace served (see fig. 4). They are strong steel pots,

FIG. 4.—DIAGRAM SHOWING LADLE AND METHOD OF POURING INGOTS; AND LINES SHOWING PROGRESSIVE SOLIDIFICATION OF INGOTS

lined with fire brick, and equipped with trunnions and shackles for crane transport. The hot metal is kept in the ladle sometimes as much as half an hour, to enable all trapped slag particles to float. Then the ladle is carried to the ingot moulds, and the metal teemed through a hole in the bottom. When one mould is filled, the metal stream is interrupted by lowering the stopper until the ladle may be moved to an empty mould. Splashing against the sides of the moulds must be carefully avoided, for such splashing is the most general cause of surface defects on the finished articles. In Bessemer plants hydraulic jib cranes are usually employed for handling steel ladles, a practice standardized before the advent of electric travelling cranes.

During pouring of the entire heat the ladle is stationary; ingot moulds are moved successively up to the nozzle by a car-pusher, a hydraulic ram which engages the side of an ingot car, and pushes it forward the required distance.

This means that the solidifying metal is jostled around more or less, a practice which causes some unsound ingots. The steel castings are ordinarily teemed in the same way; furnaces in steel foundries are usually very small as compared with furnaces serving rolling mills. 97% of all the steel made is cast into ingots.

Cavities in Ingots.—Well-killed steel contracts in volume when it changes from liquid to solid; consequently a mould poured level full will have a top cavity, or pipe, when solid. Good practice so proportions the chilling effect of the mould, the temperature of the steel and the rate of pouring that the ingot solidifies from the bottom up. A hot-top—a preheated firebrick collar—set on top of the mould, as shown, is a most useful device for keeping the top portion of the metal fluid until the last, and in condition to feed and fill the shrinkage cavity below (see fig. 4). A certain segregation or concentration of alloying elements also occurs toward the pipe; consequently all the defective top must be cropped as indicated and remelted as scrap. Segregation and piping is also minimized by casting ingots big-end-up and by slow pouring of rather cool metal. The latter is well accomplished by having several ingot-moulds on one stool, teeming into the central one, and allowing metal to rise in the others through connecting passages in the common base. Enough gas is left in most low carbon tonnage steels so a slight effervescence occurs in the mould, just enough to counteract the piping tendency. When properly made and cast, such ingots will have a flat top, a smooth solid surface, but a number of deep-seated small blow holes. During subsequent rolling these are squeezed shut and the metal welds together more or less effectively.

Stripping and Soaking.—Size of ingots depends upon the use to which the metal is to be put. Ingots of alloy steel and high grade tool steel sometimes weigh no more than 100 lb. Forging ingots are from two to five times the thickness of the biggest part of the resulting forging; those for rails, plates and structural shapes are adjusted to the size and capacity of rolling mill, and

the cross section of the desired product; for rolling mills they are generally square in cross section, with rounded corners, and about three times as high as thick. A common size is 24x26 ft. weighing about 6 tons. Forging ingots are frequently fluted hexagons or octagons in cross section. The moulds are heavy-walled iron castings, made of low-phosphorus low-sulphur pig iron, such as is suitable for the acid Bessemer process, sprayed with lime wash or other coating. When the metal in the ingot walls has well solidified, the train of moulds is moved to a stripper, an overhead crane with a vertical plunger which can be forced down by suitable gearing on top of the ingot, holding it down against the stool. A pair of stirrups then loop over the ears on either side of the mould, and lift: if the inner surface of the mould is in good condition and smooth, no difficulty is had in thus removing the mould, and it is then placed on an empty car alongside. At this time the surface of the ingot is at a full red heat, yet the interior may still be semi-fluid. To equalize this heat the ingot is placed in a soaking pit, a square fire brick chamber large enough to contain two to six ingots standing on end; an arched cover rolls aside for entrance. Auxiliary heat is supplied as necessary by a gas-air flame, operating through regenerative chequer-work, ports and auxiliary control as described for open-hearth furnaces. Pit capacity for at least 100 ingots is required to maintain a steady supply of properly heated metal to a modern rolling mill.

ROLLING MILLS

Hot Working.—A spongy lump of wrought iron, hot from the furnace, requires forging in order to squeeze out much of the trapped slag, and to consolidate the metal. Even the best ingot of steel is improved by hot work, such as forging or pressing; its fracture is changed from a coarse crystalline cleavage like sugar to a mossy or fibrous appearance associated with greatly increased toughness; it also becomes more amenable to heat treatment. Formerly all this was done on the blacksmith's anvil. Massive gun tubes and armour-plates are forged slowly in hydraulic presses; heavy engine parts, axles and cranks are beaten out by steam-hammers; repetition tools, levers and machine parts are forged under drop-hammers. In every instance the aim is to convert a steel casting (ingot) into a special shape and with improved physical properties.

Modern machines and structures—even foods and personal conveniences—require large quantities of steel parts of uniform cross section, such as plates, bars, beams, rails, pipes, sheets, etc. These are made in rolling-mills where the work is performed by passing the red hot metal through one pair of heavy rollers after another, so grooved and spaced that each succeeding pass is smaller and more nearly the required final shape. While the products of a rolling-mill vary widely in weight and shape, a common characteristic is that each piece is of uniform cross section from end to end, and is of a length limited only by the size of the original ingot, or by the size of the runout floor (*see ROLLING-MILL*).

The word *mill* may mean the entire steel making plant, just one department, or one stand of rolls in the department. Complete departments have various names, such as rail mills, structural mills, plate mills, merchant bar mills, depending upon the product they most efficiently produce. Each such mill contains a number of roll-stands of decreasing size and power, from the blooming or cogging mills which do the heaviest work, down through the intermediate stands to the last pass, finishing mill or finishing stand, which impresses the exact final cross section.

There still exist many rolling-mills, some producing the highest type of tool steel, which start with a small piece of metal (a 150 lb. ingot or a chunky rolled bar called a billet) and produce rods, bars, hoops or flats a fraction of an inch thick. Metal is passed back and forth by tongs in the hands of skilled labourers. Such roll stands are usually arranged side by side and the hot bars are looped from stand to stand, entering from alternate sides, until the final shape is produced. Sometimes curved guides are installed to do the work of alternate workmen; as the size of the bars increases hand labour cannot cope with the situation. Most rolled

shapes start from white hot ingots, perhaps six tons in weight, which are taken from soaking pits by a travelling crane, placed on the first of a series of "tables"—power driven roller conveyors—which transport the metal wherever a distant electric switch operator directs (*see Plate II., fig. 3*).

Blooming mills are usually arranged so the ingot is passed back and forth several times through the same roll stand. This requires a screw-down device and indicating dial on top of the housing for lowering and reversing the rolls progressively as the piece becomes smaller. The spindles connecting the rolls to the driving engine or motor are of most rugged construction, for upwards of 20,000 h.p. is transmitted at times.

Heating Furnaces.—In a modern rail-mill the ingot, having been reduced to a long bloom perhaps 8 in. sq. in cross section, has its ends sheared off to sound, unpiped metal by massive guillotine shears operated by hydraulic power, and is cut into such lengths that each billet will make one or two rails of required length and cross section; these are then reheated before further rolling; other mills which reheat cold billets require special furnaces, now usually gas or oil fired, frequently having waste heat boilers or recuperators (*see also FURNACE*). Furnaces have a long rectangular hearth, slightly inclined, as wide as the billet is long, and a low roof. Water-cooled skids carry the weight of the steel and prevent scraping on the brick furnace-bottom. At the cool end billets are pushed in sideways by a plunger, one by one, moving all ahead closer to the hot end. Every time a cold piece enters the furnace, a hot one is pushed out the other end on a roller table leading to a roll stand; other continuous furnaces have water-cooled rollers or other devices built into the bottoms for moving lighter pieces such as wire coils through them at a slow steady rate.

Rail Manufacture.—A reheated bloom in a rail-mill may then be given four more passes in another reversing mill, called the first roughing stand, passing then to the first finishing stand. This is three-high, *i.e.*, there are three rolls in a stand. The forward pass is through a groove cut in the lower and the middle roll; the receiving table is then elevated bodily and a backward pass is made between a groove cut in the middle and upper roll. Four such passes and a final one through a finishing stand completes the rail; a total of 15 passes and one reheating will convert an ingot into a rail weighing 100 lb. per yard. Well equipped mills produce 50,000 tons of rails per month; a total crew of 360 men per shift is required for all operations and maintenance, for straightening, drilling, inspection, loading—in fact all the operations in the finishing department. Structural shapes such as angles, channels and I-beams, are rolled in a similar routine. Frequently rail mills, by simple change in rolls, are made to produce structural steel when there is no market for rails. Special and extra heavy equipment is necessary to roll the massive H-beams with deep flanges so popular for building columns.

Plate manufacturing departments are less complicated than a rail mill, although the machinery may be more rugged. First the ingot—6 to 10 tons or even heavier—is rolled to a flat slab in a blooming mill, sheared into pieces, and the slabs reheated. Further work is done by cylindrical (ungrooved) rolls. Sometimes a single reversing 2-high roll stand does all the work; at other times two three-high mills with elevating tables may be observed. On account of the enormous bending stresses carried by the rolls when rolling wide plates, many two-high reversing stands have been built as four-high mills, having two rather small working rolls, each backed up with a larger one for stiffness. Plates of more uniform thickness, edge to centre, may be made in this way. It should be observed that the action of a rolling-mill does not widen the piece very much—most of the change in volume results in increasing its length. Consequently a heavy slab is cut to a length which equals the width of the required plate, and it enters the plate rolls sideways. Cross rolling in this way results in a better plate; metal worked in only one direction acquires transverse weakness. This means that the tensile strength of test bars cut with their axes parallel with the direction of extension during rolling will be higher than when cut from the plate with axis in any other direction. Other interesting mechanical devices are in-

cluded in a plate mill which cannot be described here in detail. Among them are plate straighteners, cooling beds, cross cut and edge shears, turnover devices, castor beds and magnetic grips. Side shearing on narrow plates may be avoided by using a universal mill, which is a roll stand to which is added a pair of stout vertical rolls. The latter are adjustable, up to perhaps 48 in. apart, and are set a proper distance to keep the hot plastic plate the exact width during its formation. Four thousand tons of sheared plates, of a variety of sizes and thickness, would be a good weekly production of a modern mill; a universal mill, working on a single thickness and width, might produce nearly twice as much, if pushed hard.

MILLS FOR SEMI-FINISHED MATERIALS

Continuous Mills.—Four classes of semi-finished materials are manufactured in such tonnage that special mills are set up to produce them, namely: sheet bars, skelp, strip and wire rods. These products are the raw material for special manufacturing plants often located at a distance from the steel furnaces. Sheet bars are worked into tinplate, galvanized and uncoated sheet; pipe is made from skelp; strip is narrow sheet for hoops and bands; and rods are drawn into wire, from which all kinds of fencing, screening, cable, nails and springs are made. Sheet bars and skelp are made in bar mills, frequently located immediately beyond a blooming mill, which take a 6 in. square bloom hot from the shear, and roll into the thin narrow plate without reheating. Such a plan requires the most rapid handling to complete the rolling before too much heat is radiated. This is done by placing a succession of two-high roll stands in tandem, within a few feet of each other, and guiding the bar automatically from one roll to the next. Since each pass elongates the piece, the speed of each roll is higher than the preceding, and the relation between speed and reduction must be nicely adjusted so the hot bar will neither buckle nor be stretched at any stage. A succession of eight or ten such rolls, with perhaps three pairs of vertical rolls to control the width—interspersed in the train, can produce standard width 8 in. sheet bars or skelp from 6 to 20 in. wide, suitable for forming into pipe up to 6 in. diameter, and from $\frac{1}{8}$ to $\frac{3}{8}$ in. thick, at the rate of 4,000 to 20,000 tons per week depending upon the sectional area of the bars manufactured. Since a mill of this sort can easily produce material far too long to ship, flying shears are set beyond the finishing roll to cut the bars to length. Many designs have been made, capable of square cutting a rapidly moving bar. Sheet bars are sometimes quenched by travelling down a long table under a series of water spray nozzles. Interesting piling devices are also in use.

Sheet Mills.—Sheets are $\frac{1}{8}$ in. thick or less, whereas plates have sufficient mass to retain heat until rolled to proper gauge, and a surface covered with mill scale is quite good enough for most purposes. Sheets, on account of their thinness and the excellent surface demanded by such finishing operations as galvanizing or lacquering, must be rolled in an entirely different manner. Most sheet mills are still operated by hand after the methods originated in Wales two centuries ago (see *TIN*) and have larger and more rugged equipment, generally producing material 18 to 30 gauge thick, whereas tin plate is smaller in area and thinner—28 to 38 gauge.

Sheet bars are cut with length slightly greater than the width of the required sheet, heated to a dull red 850° C, and rolled sideways through a two-high mill with massive cylindrical rolls, 32 in. diameter. One workman catches the bars as they come through and passes them back to another over the top roll; a third screws down the top roll gradually to continue the reduction. The crew passes two bars back and forth very dextrously; when these bars have been flattened to about $\frac{3}{8}$ in. one is placed on top of the other, the top roll raised, and the pair rolled down until each is about twice as thick as the desired sheet. In the best practice, one pass is then given in the mill to be used for finishing, in order to "shape" the pack to this mill.

By this time, reheating is necessary; the pair is opened, that is the two sheets are separated, and placed in a furnace until the temperature is up to about 800° C. Low temperatures and a

smoky flame are necessary to prevent surface oxidation in the furnace. A pair of these sheets are then further rolled to the required thickness in a finishing mill, more accurate in construction and requiring more skill to operate. For thin gauges, sheets are folded double and rolled in packs of four or even eight. Frequent opening and reheating is necessary in the latter stages of the process. They are then straightened and sheared to size.

Many surface finishes are required by customers who manufacture a multitude of objects of sheet metal. The sheets may be annealed either by being passed slowly through a long furnace with hot central zone—blue annealing—or by being piled in a tight steel box and heated for hours at a considerably lower temperature—box annealing; or the cold sheets may be given several passes through accurate rolls for a smooth surface and a somewhat stiffer temper. Interspersed with these operations, the oxide or mill scale may be removed by pickling (*q.v.*) in weak sulphuric acid. Finally the cleaned cold-rolled sheets may be dipped in white metal for a protective coat, wiped, cooled, polished and boxed. Coating with zinc is called galvanizing; tin or tin sheet is thin steel dipped in pure tin; terne sheet is thin steel dipped in an alloy of lead and tin.

Strip and Continuous Sheets.—Desire to eliminate the large amount of labour required for sheet working by the above described process has led to the recent production of sheets in continuous mills. Since 1900 it had been common to roll strip up to 3 in. wide and 16 gauge or less in thickness, in very long coils in a series of roll stands placed close together; mills have been built for wider and wider strip, until 48 in. wide strips were produced commercially in America in 1927, but no thinner than 16 gauge. In a narrow strip, hoop or cotton-tie mill, a continuous heating furnace feeds flat bars about the width of the finished piece, endwise into the first of a series of six tongue and groove rolls, perhaps 10 in. diameter. One edger may be installed after the third roll, and the remainder then be flat rolls. Then the bar passes through a series of three very accurate finishing rolls, sometimes being bent sharply, scraped, and air blasted before entering the last roll to remove the scale. These finishing rolls are cylindrical, and the guides are shifted sidewise at frequent intervals, to prevent the chilled strip from wearing the roll-surface irregularly; speeds are watched closely; the first roughing roll is very slow, the last very fast; in fact the trailing end of the billet may still be in the furnace when the front end is being reeled, 200 ft. away, at the speed of 1,000 ft. per minute. One great advantage of such close-set continuous mills is that the time of passage from furnace to finishing roll is the same for all parts of the billet; consequently the temperature at the last pass is uniform, and the thickness after cooling is also quite uniform. Finished strip is automatically turned on edge, looped back and forth on a broad slow moving conveyor belt passing through a muffle; emerging it is cool enough for reeling, cutting to length and bundling. About 40 men are required to operate such a strip mill producing from 10 to 20 tons of strip per hour, depending upon its width and gauge. Such strip has a surface covered with mill scale, or if this is scraped off, a blued colour formed during slow cooling. For higher finishes and stiffer tempers, the strip may be pickled and cold rolled rather slowly to accurate gauge and smooth surface. Wide strip is made in a very similar manner. Oxide is removed from the hot billet by strong water jets. Rolls generally are flat; edging rolls, set vertically with the exact spacing to control the width, are used more freely in the roughing train. The equipment is much more rugged and precisely built; four high stands with moderate sized working rolls backed up with very heavy stiffening rolls are utilized. Wide strip if required thinner than 16 gauge must be finished by cold rolling.

A continuous mill using more of the elements of conventional sheet mills has also been installed by the American Rolling Mill company. In this a four inch slab is rolled sidewise to rough sheets, approximately 13 gauge thick, in 14 roll-stands; midway in the line is a reheating furnace; rough sheets are sheared to length, cooled and some times pickled, then matched in pairs, and reheated in a continuous furnace. From here on the double or pair of sheets goes through a succession of rolls and furnaces placed

FIG. 5.—DIAGRAM ILLUSTRATING VARIOUS METHODS FOR MANUFACTURING PIPE. A. BUTT WELDING A 2 IN. PIPE; B. SIDE AND END VIEW OF LAP WELDING; C. HAMMER WELDING OF 30 IN. PIPE; D. DRAWING SEAMLESS PIPE; E. MANNESMAN METHOD; F. ARC WELDING OF 30 IN. PIPE

one after another in line until it reaches its proper sheet thickness; then the individual sheets are separated and stitched together into a broad ribbon for passage through annealing furnace, cooling hoods, and pickling machines; and finally cut apart and piled for shipment, cold rolling or galvanizing. Edging and guiding rolls in this system are avoided by so grinding and operating the cylindrical rolls that the sheets in process are always slightly thicker in the centre than at the edges, this convexity becoming less and less and almost vanishing in the final pass. Such a mill can produce 30,000 tons of sheets a month.

Pipe.—Skelp, the flat bars from which small sized pipe is made, is rolled in a continuous mill specially designed to produce bars true in thickness, width and properly bevelled on the edges. Frequently the finishing stand is adjustable, and a skilled workman varies the roll spacing slightly in accordance with his estimate of the temperature of the metal issuing, thus compensating for the different amounts of contraction during cooling. Skelp is cut 20 ft. long, one end pointed, and then charged into a flat hearth, properly designed to produce a uniform white heat throughout; when reaching the welding temperature the metal appears to be covered with a shiny grease, which is molten iron oxide. The operator then catches the pointed end in tongs, and by means of a draw bench (*see WIRE*) draws the white hot bar through a welding bell (fig. 5-A) forming the flat bar into a tube and pressing the butted ends together into a true weld all in one operation. Further operations reduce the pipe slightly to correct size, straighten it, remove the scale, shape and thread the ends, proof test it, and cover it with a protective coating. (*See PIPE, PIPE ROLLS.*)

Butt welding is done on pipe from $\frac{1}{8}$ to 3 in. nominal inside diameter. Common pipe from 2 to 30 in. is more usually made of flat plate by lap welding. Up to 8 in. diameter, pipe is made of plate rolled on a universal mill; for larger diameters the edges are accurately sheared (*see fig. 5-B*). Plates are piled into a furnace, heated to a dull red, and run one by one through scarfing rolls, which form the necessary bevel on the edges for an overlapping seam. The hot steel is then drawn through a forming bell which curls it up into a tube (fig. 5-A). After reheating to the welding temperature this tube is caught between a pair of rolls and rolled over a manganese steel mandrel (fig. 5-B), and the joint welded by the high heat and great pressure at the point of contact.

When the length has been rolled, the bar which has been holding the mandrel in position is withdrawn from the far end of the pipe, and the latter rolled away for the finishing operations already enumerated. It requires only a few seconds to weld a standard length pipe by either of these processes. Welded pipe over 30 in. in diameter is made by hammer welding or more recently by automatic arc-welding. In the former, the wide plate is curled on plate bending rolls and the overlapping joint heated and forged shut in sections. During the heating cycle two water-gas burners play a flame on a portion of the joint from both inside and outside; when the correct temperature is reached the lower burner is replaced by an anvil and the upper by a pneumatic hammer, and the hot spot welded and hammered down flat (fig. 5-C). The next section is similarly treated. After welding the length is re-rolled for shape and annealed, the ends sized and shaped, and the pieces tested and dipped in anti-corrosive liquid.

For arc-welding, the edges of the plate are planed to a bevelled V opening (fig. 5-F), the pipe bent to shape in rolls, clamped between long copper bars, and the bevel filled with metal from a slowly travelling wire, from which an electric arc is struck to the steel plate below. Details of the welding method are given in the article on WELDING.

Seamless Tubing.—In America, seamless tubing is preferred for all purposes where the internal pressure is above a moderate amount, and a rapidly increasing amount of such pipe is being made in diameters up to 10 in. First, a round billet at full red heat is pierced by inclined rolls and mandrel. As sketched in fig. 5-E, two 36 in. rolls of special shape are set side by side, with axes crossing and about 10° askew. The shape is such that the rolls grip the end of the ingot and spin it forward slowly, forcing it over a mandrel set between them. The operation is such that the mandrel seeks and maintains a truly axial position. After piercing the inner and outer surfaces are smoothed and the tube brought to exact size by several rollings over a mandrel, as in lap welding. Further operations from straightening to shipping are performed with considerable care. Not only is such pipe more reliable for the lack of any welded seam, but the piercing operation is so strenuous that nothing but metal of good quality can endure it. Therefore the tubing can safely withstand a considerably higher pressure than the best of welded pipe. Seamless tubes after cold drawing to thin walls are much used for structural members on

bicycles, automobiles and aircraft, and for shaping into metal furniture and machine parts. Cold drawing is done as sketched (fig. 5-D). A tube somewhat too large and thick in wall has the end swaged down slightly. All oxide is then pickled off, the tube washed, dried and dipped in tallow or other lubricant. The pointed end is thrust through a round die, and gripped by draw-bench tongs. Next, a mandrel is thrust through the tube from the far end until it has a position directly within the die, and then the tube drawn forcibly through the annular opening thus formed. In this way the outer and inner diameter may both be controlled. Each draw hardens the metal and makes it more brittle; after a few such passes, if the required size is not yet reached, the pipe is given a low temperature anneal to relieve the cold-working strains, and the process continued.

Rods and Wire.—As indicated above, wire rods are frequently rolled from 2 in. billets, 30 ft. long, on continuous mills, and the sixteenth or finishing pass delivers 2 0.2 in. round to reels at a speed of 45 m. an hour. Such a mill will produce 15 tons per hour, with a complete labour force of 45 men. Other arrangements utilize a continuous mill for breaking down a 4 in. billet, and about a dozen loops fed by hand in a cross-country mill to finish. Rod reels are dumped automatically, and the rod cold-drawn through dies, with frequent annealings and other intermediate operations, into wire of various diameters, finishes and tempers. The operations are described more fully under wire. Most of this wire is stranded into cable or wire rope, woven into screens, netting, or fencing or made into nails. All such is done by automatic machinery so economically that the increase in cost of nails, for instance, over wire is 15 cents per 100 lb., which not only includes manufacture, but the cost of the keg as well.

Cost of Rolled Products.—(Average for 1927, according to *The Iron Age*.)

	Cents per lb.
Basic Open-Hearth billets	1.49
Wire rods	1.90
Plain wire	2.41
Wire nails	2.54
Heavy Section steel rails	1.92
Soft steel bars, flats, rounds	1.84
Tank plates	1.82
Structural shapes	1.83
28-gage block sheets	3.13
22-gage automobile body sheets	4.17
Hot rolled strip	2.26
Cold rolled strip	3.05
Butt-welded steel pipe	3.50

CLASSIFICATION AND USES OF PLAIN CARBON STEELS

Production and Consumption.—Any classification which accounts for the destination of steel made by any combination of the above described processes must evidently be impossible on account of its complexity. As to process, it may be said that any of them can be made to produce steel which easily passes present commercial specifications, even for so severe a duty as railroad rails. The following figures show the distribution of American production of steel, 1922-27, according to *The Iron Age*:

Merchant bars and concrete reinforcement	18%
Sheets (except strip and tin plate)	13%
Rails and splices	12%
Plates	12%
Pipe	11%
Structural shapes	11%
Wire and wire products	9%
Tin plate	5%
Strip	5%
Miscellaneous	4%

In England the quantity of plates and tin plate is relatively larger, because of a more active ship-building industry and large exports respectively.

A similar classification of the chief lanes of consumption in the United States is given in the table which follows. It should be noted in this connection that in England and the Continent the proportion of exports is very much larger, and the relative position of automobiles and other machinery would probably be reversed.

Industry	Proportion %	Chief purchases
Railways	24	Rails
Building and construction	18	Structural shapes and bars
Automobiles	12	Sheets, strip and bars
Oil, gas, water and mining	9	Pipe
Agriculture	4	Wire fencing
Food containers	4	Tin plate
Machinery	4	Bars and wire
Exports	6	..
Unclassified	19	..

Grades of Carbon Steel.—Carbon is the principal alloying element used for hardening and strengthening iron. Consequently the utility of various iron-carbon alloys—the plain carbon steels which comprise such a large majority of the entire production—depends upon the amount of carbon present, and has led to the separation of the entire possible range into approximate grades: Ingot iron, made in a basic open-hearth furnace, has the lowest possible content of carbon and other alloying elements. It is used largely for sheets on account of its corrosion resistant properties. Extra soft or dead soft steel contains from 0.08 to 0.18% carbon, used where ductility, toughness, weldability or ease in cold working is desirable, and strength or stiffness a minor consideration, *i.e.*, for pipe, rivets, sheet, wire and case hardened parts. Structural grade or mild steel contains from 0.15 to 0.25% carbon, used where a combination of strength and easy machineability is desired, for forging or flanging operations, *i.e.*, for buildings, bridges and railroad rolling stock, for boilers, drop forgings and bolts. Medium grade contains 0.25 to 0.35% carbon and is even harder and stronger than mild steel, yet it may be hot-forged without difficulty, used for ship building, shafting and forged machine parts. Medium hard steel contains from 0.35 to 0.65% carbon, and enters into the range where the final condition and reliability is much dependent upon the past mechanical and heat treatment; it is used for large forgings for locomotives and other prime movers, car axles, and in the higher carbons for railroad rails. Hard steel ranges from 0.65 to 0.85% carbon, and is used only after it is heat treated to a correct combination of strength and ductility, used for wrought steel wheels, locomotive tires, wood cutting tools and sledges. Spring grades range from 0.85 to 1.05%, used in a heat treated condition, wherein a great range of hardness, resiliency and brittleness is possible, *i.e.*, automobile springs, cold chisels, rock drills and shear blades are made of these steels. High carbon tool steels range from 1.05 to 1.20%, used only after heat treatment for railroad springs, metal cutting and forming tools. A characteristic of these carbon steels is that each 0.01% of carbon increases the ultimate strength in the annealed condition by approximately 1,000 lbs. per sq.in., but at the expense of the ductility or toughness. Hardness also is increased.

	Ultimate strength	Reduction in area	Brinell hardness
	Lbs. per sq.in.		
Rivets	50,000	{ 30% in 8 in. }	95
Medium hard forging	75,000	20%	134
Spring steel	125,000	10%	200
Same after quenching	200,000	0	600

Combinations of even higher strengths with considerable ductility and impact resistance may be had only in alloy steels, of which a number have been developed with special properties.

USE OF ALLOY STEELS

Use of alloy steels, which prior to 1910 was confined mostly to big guns, armour and projectiles, has spread rapidly of recent years into all metal working industries, among which the automotive leads. Production in America for 1925-27 was about 24 million gross tons of ingots annually, plus about 145,000 gross tons of castings. Three quarters of this was made by basic open-

hearth furnaces, operating under very special control (alloy steel is a special steel, not merely a carbon steel to which some alloys have been added). European and British production statistics are lacking. The world production (1928) is probably about 3½ million gross tons.

Nickel and Chromium.—Although there are infinite possibilities in alloying, by far the most important steels are those containing nickel and chromium, used for crank shafts, axles, gears and other automotive and machine parts. Relatively few analyses are in use, the present tendency being to minimize the number of alloy steels in process so as to avoid mixtures of the stock. The popular nickel steels contain about 3.5% nickel and 0.10 to 0.50 carbon (Plate III., fig. 15 and 16). Chromium steels range from 0.60 to 1.50 chromium with the carbon in direct ratio from 0.15 to 1.10, stainless or rustless steel sheets contain over 10% chromium. Nickel-chromium steels are more numerous. For machine parts, one series has nickel about 1.50%, chromium 0.5 to 1.25% and carbon 0.10 to 0.50; another has about 3.0% nickel, 0.75% chromium and 0.10 to 0.50 carbon; a third has 3.5% nickel, chromium 1.5%, and carbon from 0.10 to 0.50. Nickel and chromium when added to steel increase its strength and hardness without a corresponding increase in brittleness; chromium also increases the corrosion resistance. As both elements depress the temperature and decrease the rate at which the hardening changes take place, such alloy steels can be hardened by quenching in oil, whereas plain carbon steels require plunging into cold water. This lessens the liability to crack the piece by drastic quenching, since the changes are more sluggish than in a plain carbon steel and the heat treatment routine can be varied within reasonable limits without introducing large variations in the physical properties of the finished steel. An indication of the possibilities of a 0.40 carbon steel containing 1½% nickel and 0.60% chromium, is as follows:

	Ultimate strength	Elongation
	Lb. persq. in.	% in 2 in.
Annealed	80,000	27
Quenched, tempered at 200° C	250,000	6
Quenched, tempered at 400° C	200,000	12.5

A 0.40% carbon steel without alloys would have practically zero elongation after quenching and low tempering; quenched and tempered at 400° C the elongation would be less than 12.5 and the ultimate strength only 150,000 lb. per sq. in.

Nickel steels—not heat treated—are used for structural steel in long span bridges, and high strength boiler-plates; heat treated for gun tubes, engine forgings and castings and shafting. Chromium steels are used for projectiles, for grinding rolls and for roller bearings, and with nickel or vanadium for armour plate and all sorts of heat treated machine parts, axles and gears. Rustless chromium irons, containing 12 to 18% chromium and less than 0.12% carbon, are quite workable cold. Stainless steels for cutlery have carbons over 0.30. Special alloys for corrosion resistance may contain in addition considerable nickel and silicon.

Manganese is present in all steel, but when it adds up to between 1.0 and 2.0%, and carbon 0.30 to 0.50, the steel acquires special properties. These analyses are favoured in America for high strength castings, heat treated forgings, rifle barrels and for case hardening. So-called silicon structural steel used in long span bridges and for boiler plate, is really one of the lower manganese steels of this classification. Ultimate strengths of 120,000 lb. per sq. in. and elongations of 23% are readily obtained after heat treatment. When carbon is about 0.90% and manganese 1.65, a steel is produced which has such small changes during heat treatment that it is called non-deforming or non-shrinking, and is used for intricate dies, or for gauges and other tools. The tough Hadfield manganese steel, used in castings for shock and wear resistance, contains 11 or 12% manganese and 1.0 to 1.2% carbon.

Vanadium is an element which has a powerful deoxidizing and scavenging effect; thus a vanadium-treatment on steel which shows very little of the element in the analysis makes for soundness, fine crystalline grain and reliability in forgings. From 0.5 to

2.0% is added along with other alloys to make high speed steels and tools for hot work.

Molybdenum is added to chromium and chromium-nickel steels in from 0.3 to 0.8% to widen the range of heat treatment for given values, and to improve the forging and machining properties. Some high speed steels are made where a portion of the necessary tungsten is replaced by molybdenum, but this is not favoured because molybdenum volatilizes appreciably at the high heat treatments required for those particular alloys.

Aluminium steels are useful for case hardening in ammonia gas.

High-speed Steel.—Carbon tool steels for cutting metals are heat treated by quenching from a high temperature, which gives them hardness, and then by reheating or tempering to a moderate degree to restore toughness. In use they must be operated at such low speeds that the friction between chip and tool-nose will not reheat the cutting edge above the drawing temperature, else the hardness and usefulness of the tool is destroyed. Better speeds could be made by using self-hardening tool steels, those which are hard after a slow cooling from a high temperature, such as the patented tungsten-manganese alloy invented by Robert Mushet in England sometime between 1860 and 1870, or the chromium-tungsten substitutes adapted by some American steel makers. During a 26-year research into the art of cutting metals, Frederick W. Taylor and Maunsel White discovered, 1898 to 1900, that if these steels were quenched from a sweating temperature, so high that it would utterly ruin a carbon steel, the hardness would be retained even when the cutting speed was so high that the nose of the tool and the chip leaving it were red hot. Modern high-speed steels possessing this property of red hardness fall into two general classes:

	High tungsten	Low tungsten
Carbon	0.65	0.65
Tungsten	18.0	14.0
Chromium	4.5	4.0
Vanadium	1.0	2.0

Cobalt, molybdenum and uranium have been put in as further additions by certain makers. High speed steels are made in the crucible or electric furnace, and carefully rolled or forged to break up the crystals of complex carbides forming during the solidification of the ingot and distribute them evenly throughout the bar. A well annealed bar is not very hard (Brinell 240) and can be machined into a complex tool like a milling cutter, and then heat treated; pre-heat to 850° C, heat rapidly to 1,300° C, cool in oil or an air blast, giving a Brinell hardness of at least 600. Reheating 30 min. at 600° C is then necessary to give the quality of red hardness; the Brinell hardness is even higher and the toughness materially better. As an indication of the revolution which these steels have effected in machine shop practice, a plain carbon tool steel will cut 16 ft. per min. on a medium steel forging, an air hardening steel 26 ft. per min., the same after being given the high quench 60 ft. per min. and a modern high speed steel 100 ft. per min. or more, all cuts being of same depth and feed, and on the same material.

Tungsten Steels.—Other alloys whose properties are due principally to tungsten, in addition to the air hardening tool steels and the high speed steels, are tool steels to which from 1 to 5% tungsten is added to improve the quality of the wood working or other tools which would be made of the plain carbon steels. They are also good for making finishing cuts on metal after the most of it has been removed by deep cuts with high speed steel. Magnets are also made of steels with 6% tungsten and 0.7% carbon, quenched but not tempered.

SOME FERRO-ALLOYS

Ferro-alloys are highly important and include those metallic substances used for finishing carbon steel and manufacturing alloy steel. Most of them are electric furnace alloys of iron and carbon plus the third distinguishing metal, manganese, silicon, chromium or some other, although for some purposes the carbon content

must be as low as possible. For such specifications the alloys are made using either metallic aluminium or silicon for the reducing agent.

It was early discovered that manganese must be added to make sound steel by Bessemer's process. As already noted, the usual ferro-alloy for this purpose is *spiegel-eisen*, a blast furnace product made from iron ore sufficiently high in manganese to smelt into a pig iron containing 10 to 30% of that element, with carbon about 5%. *Spiegel* cannot be used for low carbon steels because the required amount of manganese carries with it too much carbon. For such purposes, *ferro-manganese* is used, containing nominally 80% manganese and 6½% carbon. This is also a product of the blast furnace when smelting an ore containing 40 to 50% manganese, low in iron. Since manganese and iron are so alike chemically, the actions in the furnace are very similar to those previously described. The output in ferro-manganese from 50% ore is only about one third as much as though common pig iron were produced; the blast is 250° F hotter and the coke consumption twice as much; about ½ of the manganese is lost in the slag. While ferro-manganese can be made in an electric furnace of the pit type (*see ferro-silicon*) it cannot compete with the blast furnace product except under special economic conditions, as in Norway, or where carbon below 0.25% is required, as for high manganese alloy steels.

Ferro-silicon is the next most important alloy. A 12% silicon pig iron may be made in the blast furnace, but alloys higher in silicon are now used to deoxidize nearly all steel for castings, to quiet most tonnage steel from basic open-hearth furnaces, and to make several silicon alloy steels. Ferro-silicons are exclusively an electric furnace product and are made in several grades—50, 75, 80 and 95%. Carbon is about 0.5%, phosphorus and sulphur less than 0.10%—the former particularly must be kept to the minimum to prevent the alloy from absorbing moisture from the air and generating poisonous phosgene gas (PH_3). A pit-type electric furnace is employed, rectangular in cross section, with bottom built of carbon blocks. Into this shaft is suspended three carbon electrodes, one for each phase of current; a granular mixture of pure quartzite, clean iron turnings and coke is shovelled into the open top, filling the entire furnace. Passage of current from electrodes to furnace bottom gives the necessary heat for the coke to reduce silicon metal from the rock. Carbon monoxide produced by the reaction rises and burns at the top of the charge column, and a molten alloy of iron and silicon collects on the hearth, from which it is tapped periodically.

Ferro-chromium.—This is one of the earliest ferro-alloys produced in an electric furnace. At present the commercial alloys contain about 67% chromium. The so-called high carbon alloys range from 4 to 8% carbon by units, whereas the low carbon alloys necessary to make stainless irons range from 0.20 to 2.0% carbon by steps. Chromium metal up to 98% pure is also commercial. Ferro-chromiums are ordinarily made in closed furnaces of the Heroult type, with bottoms laid in carbon blocks. A charge of chromium ore, iron or iron ore, anthracite coal for reducing, and flux for slagging impurities, is mixed and shovelled in, the doors closed and electric current turned on. Carbon reduces the metallic oxides in the intense localized heat; at the finish the molten charge is poured into slabs, broken, analyzed and graded for shipment. To reduce high carbon, these varieties are remelted with concentrated chromium oxide, under a lime-fluorspar slag.

Nickel is added to molten steel as shot metal, or a nickel-steel scrap may be used to make alloy steel—nickel having no tendency to enter the furnace slag.

Ferro-vanadium is one of the most difficult alloys to make, on account of the activity of the element. Pure metal has never been produced. B. D. Saklatwalla has developed various means of commercial alloy production, using a mixture of vanadium oxide, iron oxide and powdered aluminium, either in crucibles by means of the thermit reaction, or in shaft furnaces with the assistance of the electric arc. At present the ore is smelted in a reverberatory furnace, and the vanadium concentrated in the slag. This slag is ground, mixed with carbon, iron scale and fluxes (glass cullet, lime and fluorspar) and fed in a fine stream into a covered furnace,

directly through the arc between graphite electrodes, thus effecting the reduction almost instantly in the intense heat. Reduced alloy and slag collect in the hearth and are tapped three or four times a day. A common analysis contains 35% vanadium.

Ferro-tungsten.—Tungsten ore is widely distributed, and the concentrate comes to the refiner in such complex mixtures of minerals that the first step is frequently the production of the oxide WO_3 by chemical means (*see TUNGSTEN*). This oxide is easily reduced to metallic powder without melting by mixing with fine carbon, sealing in a crucible and heating to 1,300° C for several hours. Ferro-tungsten, which has become more popular for making high speed steel, may contain from 60 to 85% tungsten, and is made in single-phase electric shaft furnaces. The bottom is one terminal; the electrode set above is surrounded by a shaft of loose brickwork, and a mixture of oxide ore, iron and carbon is filled in. As the reduced alloy builds up on the hearth it chills into a thicker and thicker button, because it has an unusually high melting point; when this solid metallic mass has grown to a point where its electrical resistance interferes with operations, the temporary furnace walls are torn down, the sow removed, crushed, analyzed and classified.

General Structure of Steel.—Much may be discovered about the general structure of the metal by a close scrutiny with the naked eye, or with a little magnifying glass. Such studies (macroscopy) include examination of the finished surfaces, of freshly broken fractures, and of rough polished sections etched in various ways. Information gained from a freshly broken fracture has not yet been systematized and correlated with microscopic appearance. To be of value it requires a keen eye to note small differences, and much practice and everyday familiarity with the fracture of satisfactory metal. In the hands of a skilled inspector it is the first step in securing uniformity in raw materials.

General Structure may best be exhibited on a roughly polished surface by etching in freshly prepared ammonium persulphate solution (10% $(\text{NH}_4)_2\text{S}_2\text{O}_8$). It shows immediately differences in grain size caused by differences in heat treatment or other cause.

Deep etching is much favoured in America for acceptance tests on high grade steel. It shows any non-uniformity in chemical composition or general bad quality. The smooth sample is held in hot concentrated hydrochloric acid for about 30 min. Impure spots, blowholes or cracks are eaten more deeply than elsewhere, and the result is an irregularly pitted surface (Plate III., fig. 8). During solidification of a steel ingot, excess of sulphur compounds will collect toward the centre and top part, where they are trapped and remain during further rolling and manufacture. The distribution of sulphur compounds in a smooth section may be shown by pressing it firmly for about a minute against a sheet of photographic paper moistened with 2% sulphuric acid, then washing and fixing. The dark areas indicate the location of higher sulphur in the steel (Plate III.; fig. 7). Phosphorus also accumulates around the borders of the large metallic crystals which form in the ingot, and during rolling or forging are pressed out into stringers or sheets in ruling directions. Ordinary plate or forging steel will always be found thus strongly marked. In forging, these *flow lines* are arranged more or less parallel to the finished surface, and the dies are so constructed that the flow lines take an easy curve around corners. Any crinkling is associated with a weak brittle region. To show phosphorous segregations a polished surface is washed in alcohol, and immersed in 10% copper-ammonium chloride. A thin copper plate will coat out on those portions low in phosphorus, leaving high-phosphorous regions bright (Plate III., fig. 10).

METALLOGRAPHY AND HEAT TREATMENT

The fact that the hardness, toughness and general desirability of a piece of steel could be profoundly modified by a simple heating and cooling has been known since time immemorial—in fact what we now know as steel was perhaps not recognized as having great merit until the fortunate discovery of heat treatment was made. This is a quite mysterious happening, this heat treatment, and it is not surprising that down through the long centuries when the art was guarded as a closed secret, many super-

stitutions arose regarding the efficacy of certain heating fires and quenching fluids, and much quackery had free scope to practice its hocus-pocus. Within the past century the chemist and physicist have done much to clear up the mystery by analyzing the various operations; we now know the essential differences between the various steels, irons, fuels, atmospheres and quenching fluids. Only since the beginning of the century, however, have intensive studies with the microscope, pyrometer, hardness and tension testing machines, brought forth a knowledge of the changes which go forward in steel or iron during a heating and cooling cycle, and working hypotheses of the causes of hardening (*see METALLOGRAPHY*).

Logically, an ingot in a soaking pit prior to rolling, or a billet in a heating furnace prior to forging, may be said to be undergoing heat treatment, but from a workshop viewpoint the term is restricted to a heating and cooling to restore original ductility and workability in a partly finished piece, or a heating and cooling—sometimes repeated—to induce special properties in the finished article.

Furnaces (*q.v.*), in regard to size, depend upon the pieces to be treated and the temperature required. A well designed furnace is one which easily attains the necessary temperature, and maintains that heat uniformly in all parts, with an atmosphere which does not deteriorate the furnace, and yet has the desired effect or no effect, upon the metal being treated. Fuels may be coke or coal, gas, oil or electricity. No source of heat, pure heat, disassociated from the products of combustion, has any virtue over another source—it is merely a matter of which is the most convenient and economical. Gas, oil and electricity are now favoured because of their ease of manipulation to give uniform temperature—choice depends upon the relative cost per thermal unit, and the atmosphere required. For instance, it is handiest to use electric resistors for heating elements in a furnace for annealing transformer sheets in a hydrogen atmosphere. Gas or oil fuel would probably be chosen for treatments on products such as roller bearings running into tons per day. Recuperators or regenerators are frequently installed to save heat. Mechanical devices for putting the metal in and taking it out, such as charging machines, furnace bottoms built on wheels or moved on rollers, revolving heating muffles and conveyors, are installed to save labour wherever the weight of material receiving uniform treatment is very great. Temperature control is most important. Well conducted shops issue definite instructions on all important work giving the rate of increase in heat, duration at heat and speed of cooling. Continuous furnaces are devised to maintain this cycle automatically. Batch furnaces are controlled by hand, or by automatic control of the fuel burners through pyrometers (*q.v.*), which are installed in all furnaces, sometimes several in a single furnace, and indicate or make a permanent record of the temperature at all times.

Atmosphere within the furnace is important. In an open flame furnace scaling (or the production of oxide on the metal's surface) may be minimized by feeding rather less air than the gas or oil requires for complete combustion. This deficiency of oxygen means that little or none will be available to react with the hot metal. In long heating of thin sheet, or long annealing of tool steel, where the surface must be preserved, the work is protected from the furnace atmosphere by closed boxes or tubes. Certain reactions may be induced during heat treatment—in this instance the material is packed in boxes with substances forming the necessary gaseous atmosphere, or the furnace is a closed muffle through which a stream of the proper gas slowly travels. Case hardening (*q.v.*), for instance, is done by packing the metal pieces in carbonaceous compounds and heating, or by piping in a gas which is principally carbon monoxide.

Quenching, to cool heated metal, may be done in various liquids, depending upon the speed required. All kinds of solutions of outlandish materials have been used, but there is no virtue in a quenching fluid except the ability to abstract heat quickly. In practice, the most drastic quench is given by a properly disposed nest of nozzles, spraying cold water at high pressure on the hot steel. Next comes a bath of iced brine; then cold water,

then high flash point oil, then boiling water, then molten lead, then air blast, then quiet air, and even slower cooling may be done in 8 hours by burial in lime; a dying furnace may require from 24 hours up to seven days. Quenching baths require methods for circulating the medium, maintaining its correct temperature either by heating or refrigerating coils, and dashing it against the metal so no air or steam bubbles remain attached to the hot metal, else soft spots will occur on an otherwise hardened surface. Conveyors or other mechanical methods of getting the hot metal rapidly into the quench and removing it when cold, are installed to save labour. In order to understand what goes on during these heating and cooling cycles, an introduction to the science of metallography and the so-called iron-carbon equilibrium diagram is necessary.

Metallography (*q.v.*) is the study of the inner structure of metals and how this varies with the chemical composition of the alloy and its past heat treatment or the work that has been done on it. It also includes the study of the relationship between the inner structure of metal and the physical properties, such as strength, toughness and hardness. In this study the use of a microscope is a long step in advance of the ancient practice of breaking the metal and looking at the fracture. It enables the student to magnify the apparent size of the grains a thousand-fold. A sample of the piece under study is given a high polish, etched slightly in a suitable acid, and placed on a microscope stage with a special illuminating device for opaque objects (*see MICROSCOPE*). The resulting structure may by appropriate means be photographed for permanent record, and for study in connection with information on its past history, and its physical strength, hardness or electrical characteristics.

Important physical properties affected by heat treatments include strength, toughness, hardness, electrical and magnetic characteristics, corrosion resistance. Of these, the first three are most relied upon. Machines and methods for making tension tests and determining the ultimate strength, elastic limit and ductility are described under **STRENGTH OF MATERIALS**. Hardness is measured by the size of impression left by a steel ball or a diamond cone weighted down by a given load. Toughness or impact strength is measured by the amount of energy absorbed from a swinging hammer by the instantaneous fracture of a standardized notched test piece.

Evidence That Metal Is Crystalline.—Viewed through a microscope, an etched metal surface presents a mosaic patchwork of interlocking and nice-fitting grains (Plate III., figs. 12 and 17). Much evidence is at hand to support the idea that these granules, despite their irregular boundaries, are crystalline; *i.e.*, the ultimate atoms are in an orderly geometric arrangement of rows and ranks. The fact was finally proven by X-rays in a manner easiest explained by this analogy: If a street lamp is viewed through a window screen the brilliant centre appears to have a series of bright rays extending outward, caused by reflections of light from every wire so placed as to throw light back into the eye. The geometric pattern of rays is caused by the geometric arrangement of the wires; arguing by analogy, if the atoms of metal are arranged in definite geometric patterns, then an X-ray beam penetrating the crystal would be reflected in definite ways and emerge in a geometric pattern, in fact, a mathematician can predict the atomic spacing and arrangement from the diffraction pattern so produced. Thus it is found that wrought iron at room temperature is in the body centred cubic arrangement. That means that if the space occupied is subdivided by imaginary planes into a space-lattice of tiny cubes regularly placed on top and to both sides of each other, the iron atoms are located at the corner of each of these imaginary cubes, and each cube will have one atom in its centre.

INFORMATION FROM TEMPERATURE CHANGES

Allotropic Changes in Pure Iron.—Much information about metal can be gained by studying the rate at which its temperature changes during uniform cooling. As long as the temperature falls uniformly, the loss by radiation is accounted for by loss in sensible heat. But suppose the surroundings are unchanged yet the

rate of cooling is arrested, or even reverses—evidently some chemical or physical change is taking place inside the metal which generates a portion of the heat which is being constantly radiated. Such spontaneous heat evolutions or absorptions, arrests in the time-temperature curves, in pure iron occur at 767, 900, 1,400 and 1,530° C. Pure iron or ferrite at room temperature consists of an aggregate of tiny crystals of so-called alpha iron, crystallized in body centered arrangement. On heating, this ferrite gradually loses its magnetism, becoming practically non-magnetic at 767° C, but without changing its atomic arrangements. This non-magnetic alpha iron has been called beta iron, and was erroneously thought to be the cause of the hardening phenomenon—it being given a fictitious hardness. At 900° C alpha iron recrystallizes on heating with absorption of considerable heat and a contraction of 1½% in volume. The elementary cubes in the space lattice now have atoms at each corner and at the centre of each face, a face-centered cubic form known as gamma iron. At 1,400° the reverse change takes place: so-called delta iron existing between 1,400° and the melting point appears to be a form of non-magnetic alpha iron, stable at high temperature. At 1,530° the metal melts, with large absorption of heat and profound change in all physical properties. Precisely the reverse changes occur on slow cooling, as noted in the following thermometric chart.

Temperature	Arrest	State
1,530° C .	..	Molten (amorphous) Melting and freezing point
1,400° C .	A ₄	Delta iron (body centered cubic) Recrystallization
900° C .	A ₃	Gamma iron (face centered cubic) Recrystallization
767° C .	A ₂	Beta iron (non-magnetic alpha iron: body centered cubic) Magnetic point, no crystalline change Alpha iron (magnetic) (body centered cubic)

A₄ and A₃ lag somewhat on reversing the direction, *i.e.*, occur at slightly lower temperature on cooling than the reverse change during heating.

Solidification of Steel.—It has been found that iron containing a little carbon starts to solidify on cooling at a lower temperature than 1,530° C (the melting point of pure iron) and furthermore that this depression in the freezing point is greater and greater the more and more carbon is in the melt. This is plotted graphically in line AB in fig. 6. Line AB is called the liquidus; at all temperatures and compositions above and to the right of AB the alloy is molten. Hot solid iron at 1,130° C will dissolve 1.7% carbon, and rather less as the temperature increases. This relationship is also plotted by the line AE, called the solidus. At all temperatures and compositions below and to the left of AEB the alloy is solid. The region between the liquidus and the solidus denotes that at those temperatures and compositions the alloy is in a mushy state, part solid, part liquid.

The way a 1% carbon steel solidifies is worthy of study. Its condition at any temperature may be investigated by drawing a vertical ordinate at the composition representing 1% carbon. The diagram shows immediately that the first solid material appears on cooling to 1,450° C (point m). This solid is not pure iron, but a solid solution of carbon in iron whose chemical composition is found at point n on the solidus (about 0.2%). This solid is much richer in iron than the melt, so its appearance leaves the melt richer in carbon, and it must be cooled further before more solid appears. Thus, by continuous solidification of iron poor in carbon and drop in temperature, the sample reaches let us say 1,400° C. At 1,400° C the melted portion has acquired a composition represented by point p (about 1.6% carbon), and the solid appearing from it is a solid solution containing 0.4% carbon (point q). And so it goes: at 1,300° the remaining mother liquor has 2.7% carbon; the solidifying material has 0.8% carbon.

The first-formed solid material will act as a nucleus for the later which solidifies as the melt chills down. This causes the early-formed solid, low in carbon, to be in contact with later-formed solids higher in carbon. Yet at this lower temperature

the material in the cores of the crystals has a greater capacity for carbon than it had before, since the solubility of carbon increases with decreasing temperature down to 1,130° C, and there is a pronounced tendency for carbon to pass from the high carbon melt, inward through the outer crystalline layers, until the carbon content of the solid solution becomes more nearly uniform. It requires a very slow cooling or a long annealing to cause entire equalization of carbon; the so-called solid solution alloys cast and cooled at normal rates, usually show a cored structure under the microscope, caused by systematic variations in chemical composition between the material first solidified and the last freezing mother liquid. Assuming that the cooling has been very slow, and the equalization of carbon in the solid portions perfect, the last of the mother liquor in the 1% steel disappears at 1,230° C (point r, fig. 6); the metal is entirely solid.

AUSTENITE

Solid Solution.—Since the word solution ordinarily connotes a liquid, the term solid solution appears to be a contradiction of terms. The solid solution of iron and carbon is so important that it has been given a special name, austenite, in honour of the English investigator and metallurgist, Sir W. Austen. If any steel is annealed to a temperature of 1,130° C, the temperature of maximum solubility of carbon in gamma iron, quenched so rapidly as to prevent changes on cooling, etched, and examined under the microscope it will look like a pure metal (Plate III, fig. 3); *i.e.*, a series of abutting crystalline grains of uniform appearance—saving the slight coring which may remain after insufficient anneal, or some surplus material insoluble under any conditions. Thus the solid solution has some of the essential characteristics of a liquid solution—it is a uniform dispersion of atoms of one element amongst atoms of another, and the proportions may be anything within the limits of solubility. Austenite in fact is an aggregate of crystals of gamma iron; iron atoms are arranged in the face centered cubic system, within which are tucked away the carbon atoms here and there inside the space lattice.

Decomposition of Austenite.—Another similarity between the solid solution austenite and such liquid solutions as salt in water is that the mutual solubility of carbon in iron, or iron in carbon, whichever appears to be the excess element, changes with lowering temperature, and the then insoluble substance crystallizes out. Such changes can occur in the atomic arrangement in entirely solid metal. The latter is not a fixed and entirely rigid structure, except perhaps at absolute zero. The atoms, while they do not wander about at random, as in a liquid, are in a state of thermal agitation and are moving in small orbits or oscillating back and forth with more and more vigour as the temperature goes up. Under such circumstances considerable rearrangement may take place by interchange of position, or by stranger atoms slipping through the open spaces in the crystalline lattice. Such crystalline rearrangements generally occur in a reasonably small temperature interval, involve an evolution or absorption of heat, and consequently are recorded on time-temperature or cooling curves.

Cooling curves on a low carbon steel show that the change occurring in pure iron at 900° C from gamma to alpha form is lowered progressively with the increasing carbon content. Furthermore a new and important evolution of heat occurs in all steels at about 690° C, increasing in intensity as the carbon goes up. These two temperature arrests, called A₃ and A₁ respectively, coincide at 0.9% carbon. At higher carbons two diverging temperature effects are again noted. All these facts are noted on fig. 6, the steel end of the iron-carbon equilibrium diagram, by the lines GSE and PSK. This is an underlined V, a shape familiar to the physical chemist as noting the break up of a solution into two mutually insoluble constituents. In the case of steel, the solution is austenite; the excess constituent first precipitated out in low carbon steels is pure iron, or ferrite, while that first appearing in the highest carbon steels is not carbon but an iron carbide, Fe₃C, called cementite. A 0.9% carbon steel corresponds to the eutectic. Since it appears in a solid solution it is termed a eutectoid. If examined under the microscope, a slowly cooled 0.9%

carbon steel is made up of tiny flake-like crystals of iron and iron carbon, arranged in rough parallelism and having a pearly lustre. Hence its name pearlite (Plate III., fig. 13). A cooling eutectoid steel reaching 690°C is simultaneously saturated in both constituents—they separate out simultaneously, side by side, in closely intermixed crystals.

Structure of Low Carbon Steels.—The mechanism may be illustrated by studying a cooling steel containing 0.25% carbon

FIG. 6.—EQUILIBRIUM DIAGRAM OF IRON AND CARBON

(line t u). Pure iron starts to be precipitated when the temperature reaches 820°C (point v) and more and more pure iron crystallizes out as the temperature falls, leaving a mother substance richer and richer in carbon. This action continues until at 690°C the remaining solid solution has reached saturation (point S, 0.9% carbon, the eutectoid) and that portion then rearranges itself into pearlite. Plate III., fig. 12 shows the microstructure at the end. The larger clear crystalline grains are pure iron; the gray specks are pearlite (high magnification is necessary to show the laminated structure). Medium carbon and hard steels have relatively less and less free ferrite, and more and more pearlite. A 0.9% carbon steel is all pearlite (Plate III., fig. 13). Slow cooled higher carbon steels (so-called "hyper-eutectoid" steels) have excess cementite in white veinlets surrounding pearlite masses (Plate III., fig. 2). Reverse changes to those described above take place on heating; that is, a well crystallized slowly cooled steel again reverts to a uniform solid solution when heated above the line GSE.

Structures in Quenched Steel.—The above described changes take place in a slowly cooled steel. If cooling is more rapid, time is not given for the atomic rearrangements necessary for such complete recrystallization, and certain intermediate microstructures may be observed. The most rapid quenching of austenite may be able to preserve this structure unchanged in the cold metal. In fact this can be done, especially in steels with considerable alloying elements like manganese or chromium. X-ray investigation of such a specimen as Plate III., fig. 3 proves that the metallic atoms build up a face-centred crystalline lattice characteristic of gamma iron. The carbon atoms are more or less uniformly distributed, but not combined in any definite compound. Such quenched austenitic steels are exceedingly tough; while they are not so hard as other steels under the Brinell test, it is impossible

to cut them with a chisel; they resist wear, scour and impact well. High manganese steels are therefore suitable for such things as steam-shovel teeth and rail crossings.

High carbon steels, without alloying elements, can seldom be quenched rapidly enough to preserve pure austenite. Under the microscope a polished and etched surface appears to be criss crossed with sharp needles (the lighter portions of Plate III., fig. 14). This structure has been given the name martensite; it is the hardest and most brittle condition of steel. X-ray studies show that the iron has completely transformed into the body-centred crystalline lattice of alpha iron; it also indicates that the new crystals of ferrite are exceedingly small, far below the ability of the microscope to see. The needle-like markings are relics of the larger austenite grains rather than actual structures of martensite.

At the interior of a quenched high carbon steel specimen, where the cooling rate is slightly slower than on the surface, the martensite needles may be mixed with rounded areas which etch much more rapidly, appearing black in fact. This structure is called troostite (also shown in Plate III., fig. 14). Troostite also appears in a lower carbon steel rapidly quenched; or in a martensitic steel which has been reheated or drawn in boiling water. In troostite the carbon atoms, insoluble in alpha iron, have had the opportunity to form sub-microscopic crystals of cementite. None of the crystals have grown to a point where they can be seen even at 5,000 magnifications; however, the X-ray proves it to be an aggregate of excessively small crystals. Troostite, while still almost as hard as martensite is noticeably less brittle.

If the hot steel be given a slightly better chance to crystallize, as for instance, quenching a hot bar more slowly in oil, or tempering to a blue colour, the resulting structure is again changed (Plate III., fig. 1). A characteristic cloudiness appears, giving a suggestion of ill defined crystalline grains. This is called sorbite. A steel tempered to sorbitic structure has lost some of the hardness of martensite, but the added toughness is so marked that it is the desirable condition for sledge faces. Sorbite represents a further stage in the growth of ferrite and cementite crystals. When these crystals can be distinguished clearly the structure is as illustrated in Plate III., fig. 13, containing well defined regions of pearlite (intimate mixtures of iron and cementite crystals). A further stage is noted in long anneals at temperatures just under A_1 . The plates of cementite break up into little balls. This condition is called divorced pearlite or spheroidized cementite—the most easily machineable condition in a high carbon steel.

THEORY OF HARDENING AND TEMPERING

"Slip Interference."—These various actions which go on within solid steel at moderate temperatures are of the greatest commercial importance, for they control the important operations of hardening and tempering steels. In the simplest example these consist of slowly heating the steel to a temperature somewhat above line GSE, holding it there long enough for it to become a uniform solid solution, then quenching it rapidly thus retarding the reverse reactions as much as possible, and finally reheating the quenched bar moderately to produce troostite or sorbite, still hard but much less brittle than the freshly quenched structures. The most widely accepted explanation of the hardening phenomenon is known as the *slip interference* theory, definitely formulated and systematized by the American metallurgists Zay Jeffries and R. S. Archer. It starts with the knowledge that metals are crystalline, and that metallic crystals when they are stressed beyond the elastic limit, do not tear apart irregularly, but one portion slides past another portion along definite crystalline planes without appearing to let go. Such motion is speedily jammed and stops because it tends to disarrange all the neighbouring crystals. The slip plane also heals immediately. Much of the hardness of quenched steel is believed to be due to the sub-microscopic size of the constituent crystals; the boundaries of each one interfere with slip under stress in all the neighbours; since slip cannot occur, the metal resists deformation, and is therefore hard. In steel another hardening factor supplements this slip interference at the grain boundaries, namely, the presence of a great number of carbon atoms, cementite molecules or even tiniest cementite crystals

uniformly dispersed through the ferrite grains. Such particles harden the entire metal from two causes: first, they prevent the start of any slip between crystalline layers as would billions of tiny staples in the leaves of a book; and second, the slips once started despite this hindrance must drag against a multitude of anchors.

Hardening by Cold Work.—Since a ductile metal like iron deforms plastically under cold work or stress beyond the elastic limit by internal slip along crystalline planes, it would appear that this slip has the effect of breaking up the original crystals into numbers of small ones. For that reason cold work hardens the metal; finer grained metals are harder. Under the microscope the slip planes are seen only in special circumstances, but the original grains appear to be flattened out and assume a shape more or less parallel to the extension. In extreme cases, as in wire for suspension bridge cables, a high carbon steel with original tensile strength of about 80,000 lb. per sq.in. can be cold worked into a condition where it will carry 220,000 lb. per sq.in. before rupture. Micro-structure of such a wire parallel to the direction of drawing shows the original crystalline boundaries flattened out until the structure seems to be fibrous (Plate III, fig. 11).

Increase in hardness is accompanied by an increase in brittleness, so excessive cold work is liable to break the article, either during manufacture, or in its after history—season cracking. To avoid this danger, and to restore ductility, the piece may be annealed (*q.v.*) or reheated moderately to a point which does not affect the microscopic appearance yet the added atomic mobility at the higher temperature permits such rearrangements as necessary to relieve the stress.

Recrystallization.—A little higher heat on a cold worked piece of metal will cause the previous grain structure to be entirely replaced by a new arrangement. This is known as recrystallization. The recrystallization temperature varies with the amount of cold work previously done on the metal. Long stay at temperatures above this will cause the growth of large crystals. Such is to be avoided because it makes for a condition known as Stead's brittleness. Slip planes started across a large crystal find less supporting material at the grain boundaries, and the self-healing action ordinarily occurring during plastic deformation is absent; the big crystal splits along the cleavage plane.

Refining the Grain.—Recrystallization by moderate heat after cold work is to be distinguished from recrystallization on a higher heating to above the line GSE. The alpha iron then transforms into crystals of gamma iron. Apparently the new crystalline arrangement is almost entirely independent of the old; if the temperature is maintained for some time the new set of austenite crystals grow in average size as the temperature or time increases. On slow cooling through the transformation range these new austenite grains eject the excess constituent to the borders, and the kernels are the locus of the pearlite regions.

Thus by a heating and cooling through the transformation range, the grain size of steel can be changed, refined or enlarged, as desired. Since previous effects of work or hardening are wiped out by such an anneal, the process is frequently called normalizing.

Burning.—Excessive heating of steel ruins it by burning. A burnt steel is brittle and the brittleness cannot be removed by heat treatment. Microscopic examination shows that the grain size is unusually large, due to the high temperature experienced, and the grain boundaries contain considerable oxide. Burnt steel in fact has been heated beyond the solidus (line AE) and the high carbon regions in the austenite have actually melted. The melted metal absorbs furnace gases very quickly, which are responsible for the incurable damage done in the molten portions of the steel.

BIBLIOGRAPHY.—The fullest account of American practice is contained in J. M. Camp and C. B. Francis, *The Making, Shaping and Treating of Steel* (1925); for British and Continental see F. W. Harbord and J. W. Hall, *The Metallurgy of Steel* (1923); H. P. Tiemann, *Iron and Steel* (1919), a pocket dictionary of terms and a brief encyclopaedia of the whole subject. Some fine text books cover only portions of the subject, such as Robert Forsythe, *The Blast Furnace and the Manufacture of Pig Iron* (1922); D. Carnegie and S. G. Gladwyn, *Liquid Steel* (1913); A. W. and Harry Brearley, *Ingot Moulds* (1919); D. K. Bullens, *Steel and its Heat Treatment* (1927); Z. Jeffries and R. S. Archer, *The Science of Metals*

(1924), and R. M. Keeney, "Manufacture of Ferro-Alloys" (1914), in U.S. Bureau of Mines *Bulletin* 77. Professional societies which devote much attention to the manufacture of iron and steel, and whose journals contain accounts of the current state of the art are the (British) Iron and Steel Institute, The American Iron and Steel Institute, and the American Society for Steel Treating. Leading journals of the trade are *The Iron Age*, New York; *Iron and Coal Trades Review*, London; and *Stahl und Eisen*, Dusseldorf. (E. E. T.)

IRON AND STEEL: WORLD'S STATISTICS. In tracing the development of the world's iron and steel output it is necessary to commence with Great Britain, for although the output of pig iron in Great Britain was in 1927 only 8.7 per cent of the world's total and of steel only 9.2 per cent, nevertheless Great Britain was the birth-place of the modern iron and steel industry, and most of the developments connected with the industry originated there. Until 1871 the output of pig iron in Great Britain exceeded that of all other countries put together; in 1890 Great Britain was for the first time surpassed by the United States; in 1904 for the first time by Germany, and in 1921—owing to a coal stoppage—for the first time by France, who, with Alsace-Lorraine restored, surpassed Great Britain again in 1924.

According to Mushet the output of pig iron in Great Britain in 1720 was 17,350 tons but T. S. Ashton, in his *Iron and Steel in the Industrial Revolution*, gives reasons for thinking this too low, preferring the estimate of William Rea, an ironmaster of Monmouth, who put the output of pig iron at this period at about 25,000 tons per annum; he also points out that Scrivenor's *History* (p. 57) wrongly gives 1740 as the date of Mushet's estimate, an error which has been followed by almost all writers since. The 25,000 tons produced in 1720 had risen to 68,300 tons by 1788; but, whereas the majority of the furnaces in 1720 had been charcoal, 55 in 1788 were coke furnaces. It is not possible to describe the reactions of improvements in blast furnaces upon the demand for iron, nor of the demand for iron (created by engineering inventions) upon blast furnace improvements; suffice it to say that by 1840 production of pig iron had risen to 1,396,000 tons; by 1860 to 3,890,000 tons; and by 1880 to 7,750,000 tons. Having nearly trebled in the 20 years between 1840 and 1860 and doubled between 1860 and 1880 the increase between 1880 and 1900, was no more than 16%, while the output in 1920—the highest post-war year—was actually less than in 1900.

It was not until Bessemer's invention in 1856 that the production of steel suitable for rails, etc., at relatively low prices was rendered possible. This was followed by the discovery of the "open hearth" process of steel manufacture by Siemens Bros. in 1864-67; but the most far reaching development, since it rendered available for steel-making large deposits of ore previously unusable, not only in this country but also in France, Luxemburg, Germany and America, was the invention conceived by Mr. Sydney Gilchrist Thomas in 1877, and perfected, in conjunction with his cousin in 1883, whereby phosphorus was removed in the Bessemer and Siemens processes. In 1870 the output of steel in Great Britain was 220,000 tons: in 1880 1,290,000 tons: in 1890 3,580,000 tons: in 1900 4,900,000 tons: in 1910 6,370,000 tons, and in 1920 9,070,000 tons: this figure having been exceeded during the war in 1917 when the output was 9,720,000 tons.

It is impossible to trace, even in this broad outline, the progress of development in the other iron and steel producing countries. In all cases except where the industry is of comparatively recent growth, iron was first smelted with charcoal, and coke but slowly won its way: e.g., mineral fuel was first used in France in 1782, but by 1819 only two furnaces were using coke out of a total of 350 (*Memoirs of the Geological Survey of Great Britain*, vol. i, pt. 1, 1856, quoted by Ashton): but in all countries the great bulk of the steel output is made either by the Bessemer or Siemens process with, of course, local modifications and improvements.

Pig Iron: World Output.—The following table gives the world production of pig iron at the end of each decade from 1820 to 1920: in 1913, and in each post-World War year.

It will be seen that whereas in the hundred years ending 1910 the increase in any decade was never less than 47% and the average rate of increase throughout that period was nearly 60%, the world output in 1920 was actually less than in 1910 and even in

1927 the output was no more than 31 per cent above 1910. The major reason for the slow growth since 1913 (in 1911-13 the rate of progress was fully equal to that in the preceding decades) was the dislocation caused by the World War with a contributory minor reason that since the war a greater proportion of scrap and a smaller proportion of pig iron has been used in steel-making. The rate of progress of steel output has also been checked by the

TABLE I. *World Output of Pig Iron at the End of Each Decade 1820 to 1920, in 1913, and in Each Year Since 1920*

Year	Output: tons	Increase per cent per decade
1820	1,000,000	33*
1830	1,800,000	80
1840	2,700,000	50

war, but, owing to the increased use of scrap, the increase in output in 1927 compared with 1910 (69 per cent) is much greater than in the case of pig iron.

Outputs of Pig Iron and Steel by Chief Countries.—The following tables give the output of pig iron and steel of the chief producing countries, of pig iron at the end of each decade from 1850 onwards, and of steel from 1870 onwards, in 1913 and in each year since 1920:—

*Luxemburg is included with Germany 1850 and 1860.

†Since 1920 Lorraine is included with France. ‡Russia, Poland, Norway, Sweden, Italy, Austria-Hungary, Czechoslovakia, Spain, Canada, Australia, India, Japan and China.

In 1913 the output of both pig iron and steel in Great Britain was higher than in any previous year, but the capacity of British steel works was not equal to the war demand for steel especially when the requirements of the allies, much of whose steel producing area was over-run, are taken into account. Considerations of time and man power made it impossible to expand the capacity for the manufacture of pig iron to the same extent as for the manufacture of steel, and British pig iron capacity was, therefore, only increased by about 1,000,000 tons per ann. (from 11,000,000 to 12,000,000) while steel capacity was increased by about 4,000,000

per ann. (from 8,000,000 to 12,000,000). The lack of balance thus resulting was met by restricting the use of pig iron for purposes other than for steel making, by the increased use of scrap, and by importation from America.

*Prior to 1920, Lorraine is included with Germany, but since that date with France. †Russia, Poland, Sweden, Italy, Austria-Hungary, Czechoslovakia, Spain, Canada, Australia, India, Japan and China.

The British production of steel since the war has never equalled the production of 1917, and the production of pig iron has fallen far short of pre-war years. In the case of steel this is due partly to the depression in shipbuilding since 1920 but chiefly to the decline in exports for, in spite of the depression in shipbuilding, home consumption in most post-war years has exceeded that in pre-war years owing to increased demands in other directions.

Iron and Steel Exports.—Table IV, which gives the exports of iron and steel (as far as possible according to the Board of Trade's classification) from chief producing countries shows that exports from Great Britain have not yet reached the record figure of 1913 when they amounted to nearly 5,000,000 tons. The best British post-war years have been 1923, when exports from European countries were curtailed owing to the Ruhr occupation, and 1927 when arrears accumulated during the coal stoppage of 1926 were being worked off. The decline in the British export trade has taken place in spite of great reduction in prices for, as shown by the Board of Trade's price index number, prices of iron and steel products have been falling since the end of 1920, and in March, 1928, prices were on the average only 13% above 1913.

*Includes Luxemburg and Saar in 1913. †Includes Saar from 1925. ‡Includes Luxemburg fr. May 1922. §Fisc. yr. ended June 30, 1913.

After a world war, during which the great bulk of iron and steel produced was immediately consumed, it is clear that the potential demand for iron and steel must be considerable, but in the early post-war years most countries were too impoverished to make that demand effective, whilst the belligerent countries who before the war supplied capital for development were no longer able to do so on the same scale. As the world slowly recovered from the effects of the war and purchasing power increased the advantages enjoyed by European countries in their depreciated exchanges, longer working hours, lower standard of living, lower

transport charges, etc., enabled them to quote substantially lower prices than Great Britain and to supply an increasing proportion of the world's needs. The table therefore shows that, while the exports from Great Britain have declined, exports from the other European countries have increased.

As in the case of Great Britain so in France the year 1913 had been one of maximum production, and France produced 5,126,000 tons of pig iron and 4,613,700 tons of steel in that year. As a result of the war, Alsace and Lorraine were added to France and these provinces produced in 1913 3,809,400 tons of pig iron and 2,250,700 tons of steel. The total production of France, as now constituted, therefore in 1913 amounted to 8,935,400 tons of pig iron and 6,864,400 tons of steel. On the other hand, a great proportion of the area in which the iron and steel works were situated was either occupied by Germany or was within range of the German gunfire, so that 63 per cent of the French iron and steel industry was out of commission during the war. France attempted to compensate for this to some extent by building new works in the non-invaded area, and, as soon as the war was over, proceeded to rebuild the devastated areas so that the French iron and steel making capacity within the 1913 boundaries is now considerably in excess of pre-war, and in 1927 France produced 9,150,000 tons of pig iron and 8,140,000 tons of steel. This increased production necessitates a much bigger export of iron and steel from France than formerly, and although the Peace Treaty and subsequent Franco-German agreements provided that a certain quantity of iron and steel should find an outlet in its former market in Germany, France has still to market a great proportion of her output on the world's markets, and this is perhaps the biggest of many factors contributing to the internecine competition which has been experienced in the past few years. It will be seen from Table IV. that French exports have been rising for the last few years and reached 5,602,500 tons in 1927.

The production of pig iron in Belgium in 1913 amounted to 2,445,900 tons, and of steel ingots and castings to 2,428,100 tons; as in the case of most other producing countries this was very nearly equal to capacity. During the war nearly all the plant was destroyed, completely or partially, and the works have had to be reconstructed and are, therefore, up to date. The effect of the rebuilding has done very much to augment the productive capacity of Belgium, and in 1927 3,693,000 tons of pig iron and 3,656,200 tons of steel were produced, or about 50% in excess of the 1913 output. A great proportion of Belgium's production of iron and steel requires to be exported, but a comparison with 1913 is no longer possible since Luxembourg is now included with Belgium whereas prior to the war Luxembourg counted with Germany. Exports of iron and steel from Belgium alone in 1913 amounted to 1,550,900 tons and from Belgium and Luxembourg together in 1927 to 4,606,900 tons.

The production of pig iron and steel in Germany in 1913 (as then constituted and excluding Luxembourg) amounted to 16,500,000 tons and 17,323,800 tons respectively. Germany was thus the second largest producer of iron and steel in the world. Having lost Lorraine, part of Silesia and the Saar as the result of the war it was only natural that she should endeavour to make good this loss by extending existing works and by building new ones within her contracted borders; so in 1927 Germany produced in her post-war area 4,000,000 tons of steel more than were produced in the same area in 1913, the total production of 1927 being equal to that of pre-war Germany in 1913. The production of pig iron and steel in 1927 was 12,897,800 tons and 16,056,700 tons respectively.

American Progress.—The output of pig iron in America in 1913 amounted to 30,966,000 tons and of steel ingots and castings to 31,301,000 tons. The enormous contracts for steel shells, guns, machine tools, etc., placed by the Allies during the war, as well as the demands for equipping her own army when the United States entered the war, necessitated the extension of existing iron and steel plants and the erection of new ones.

Stewart, in dealing with the history of iron and steel prices in America during the war, states:—

"The demand for steel was so insistent that, in spite of the increased

output, prices continued to rise at an unprecedented rate. . . . In Aug. 1916, after two years of war, market prices of pig iron had risen 38%, and steel billets 130%. The effectiveness of these prices in stimulating production cannot be questioned. The prices were high enough not merely to maintain production but to persuade producers to increase their productive capacity in spite of the high cost of construction and the knowledge that the war demand for steel could not long continue. Out of the profits yielded at these prices the industry could provide for a rapid rate of depreciation and obsolescence and still show enormous gains."

After the war, the great increase in capacity for iron and steel production was absorbed by the increased internal demand, and in 1927 the output of pig iron in the United States amounted to 36,565,600 tons, and of steel to 44,940,000 tons. Exports of iron and steel which in 1913 had amounted to 2,906,500 tons amounted in 1927 to 1,942,700 tons.

With regard to the future, the British Committee on Industry and Trade (Balfour Committee) which reported on the iron and steel industries in May, 1928, pointed out that had the world's output of iron and steel continued to grow at the pre-war rate the output in 1927 would have amounted to about 140,000,000 tons of pig iron and 150,000,000 tons of steel instead of the 85,000,000 tons and 100,180,000 tons shown in Tables II. and III. above, and although world output could not be expected to increase indefinitely at the pre-war rate there is no indication that the maximum production has yet been reached. (M. S. B.)

IRONBARK, the name applied to species of *Eucalyptus* (*q.v.*) in Australia, from the hardness of the bark.

IRON CROSS. A German decoration, instituted in 1813 as a reward for distinguished service in the War of Liberation. (See MEDALS.)

IRON IN ART. Iron work is a term used generally to denote anything made of iron, but specifically applied to the designing and handicraft of iron as a work of art.

HISTORY

The working of iron has engaged the activities of the human race from remote antiquity, especially in the continents of Europe and America. The metal ore exists in vast quantities in the soil, indeed there seems to be no limit to it, and each succeeding year records its discovery in some new place. The pure metal is obtained from the ore by the process of smelting, some primitive form of which was known in early times even by uncivilized races. It was not difficult to fill a cavity with ore and charcoal, and leave an opening for the wind to produce the currents necessary for fanning the flame and raising heat. Wood and charcoal were employed for producing the necessary heat, but in England, in 1611, a patent was taken out for smelting iron with coal, though 100 years passed before Abraham Darby, the first of that name, brought the process into common use. The result was in the form of rough bars of iron called pigs.

The working of iron is referred to in China some thousands of years before the Christian era, and it is found in India at a later date. Its use was known in Chaldaea, Assyria and ancient Egypt. References in the Old Testament suggest that the Hebrews also were acquainted with it. The Greeks are credited with the art of casting statues in iron. Later the Romans profited by the Greeks' knowledge. Currency bars of iron which have been found by the hundred in various parts of England prove that the Roman occupiers found iron very useful as a medium of commerce.

THE MEDIAEVAL PERIOD

England.—By the 10th century iron-working among the English was as fully developed as at any time during the next three centuries. It appealed to the sturdy English temperament as a difficult material calling for swift action; it suggested strength, stability and protection, all of which qualities were in those days not to be ignored. Its first use was purely protective; enemy attacks were frequent, and doors had to be strengthened with massive iron-work inside and out. Window openings, especially those of the treasuries of mansions and cathedrals, were filled with strong interlacing bars of solid iron; a good example remains at Canterbury cathedral. When in course of time the need passed away, there came greater freedom of work and a

IRON FIREPLACE IMPLEMENTS

1. Iron Fire-back. The Royal Oak of the Stuarts and the arched crowns date this work in the reign of Charles II. (1660-85)
2. Fire-dogs and implements of cast iron. In common use in England during the 16th and 17th centuries

definite intention of ornament. Throughout England, church doors are found with massive iron hinges, the bands worked in rich ornamental designs of scroll-work, many of them probably the work of local smiths. They vary from the plain hinge-band with crescent to the most elaborate filling of the door. Examples exist at Skipwith and Stillingfleet in Yorkshire, many in the Eastern counties and others in Gloucester, Somerset and the

FIGS. 1 & 2.—FORGES: BELLOWS OF MEDIAEVAL PERIOD, OPERATED BY HAND OR FOOT; THE MODERN HAS A MOTOR-DRIVEN AIR-PUMP

west Midlands. The next movement came with the erection of the great cathedrals and churches, whose shrines and treasures demanded protection. Winchester cathedral possesses the remains of one screen with a symmetrical arrangement of scroll-work. The grille above the tomb of Queen Eleanor at Westminster Abbey recalls the maker Thomas de Leghtone, a master-craftsman in iron who had succeeded another great smith, Henry of Lewes. Tombs were enclosed within railings of vertical bars with ornamental finials at intervals, such as that of the Black Prince at Canterbury. A third development appeared in the early years of the 14th century when the smith, working in cold iron, attempted to reproduce Gothic stone tracery in metal. This work was more like that of a joiner than of a smith, being often in small pieces chiselled and riveted, and fixed on a background of sheet-iron. A typical example is in Henry V.'s chantry at Westminster Abbey; but the most magnificent is the great grille at St. George's chapel, Windsor, made to protect the tomb of Edward IV. For many years it passed as the work of the Fleming, Quentin Matsys, but it is now known to have been executed by an Englishman, John Tresilian. Many small objects such as door-knockers, handles and escutcheons are to be found executed in the same manner. Smithing declined in England during the 16th century.

France.—In door-hinge ornaments France followed much the same line as England, and beautiful work is found on church doors, especially in central and northern France. It reaches a height of greater elaboration and magnificence than in England, the culminating point being seen on the west doors of Notre Dame, Paris, the ironwork of which is so wonderful that it was attributed to superhuman agency. Grilles at Troyes and Rouen reveal a high standard of excellence, but tomb-rails found no favour. What we have called "joiner's" work was immensely popular; it was applied to small objects such as door handles, knockers, ambry doors, and above all to locks, which exhibit an amazing amount of detail and a delicacy of finish such as could only come from a French craftsman. France has succeeded in preserving more of its mediaeval work than England.

Germany.—In Germany the door-hinges present greater stiffness than those of France. Examples exist at Nuremberg, Magdeburg and elsewhere; unusually fine locks and other objects in Gothic architectural style are common enough. Rich pierced work is also found and hammered work of an heraldic character, but the German smith of the period had not the same understanding of Gothic work as his French neighbour.

Belgium.—Belgium made a late start in the working of iron, but the number of objects still existing such as candelabra, fontcranes, lecterns and gable crosses, show an extended application and thorough knowledge of the art. The iron well-cover by

the cathedral at Antwerp which dates from 1470 enjoys a wide reputation. The Matsys family of Louvain were celebrated smiths.

Spain and Italy.—Spain followed much the same lines, the craftsmen imparting to their work the characteristic richness and elaboration of their Gothic architecture. Italy seemed hardly at home with iron, and was content to adopt the easiest methods of workmanship. The screen of the Scaliger monuments at Verona, a grille at Santa Croce, Florence, and another at Siena, give an Italian rendering of Gothic tracery with panels of pierced sheet-iron.

The end of the mediaeval period in Europe found the smith departing from legitimate design in his work and indulging in methods hardly appropriate to his material; attractive as the result is, it does not satisfy our sense of what work in iron should be, nor did it serve to bring out the power of the craftsman.

THE RENAISSANCE PERIOD

Italy.—It might have been thought that in the home of the Renaissance, ironwork would have proceeded at the same pace and with the same brilliant success as architecture, sculpture, bronze-casting and the other arts. Strangely enough, little use of it is found in connection with the fine buildings of the revival. Bronze was favoured, and what in other countries is found in iron has its counterpart in Italy in bronze. The manual labour involved in the use of iron did not commend itself to the Italian temperament, and as time went on the smiths grew less inclined for the more difficult processes of hammering and welding, and contented themselves ultimately with thin riband iron, the various parts of which were fastened together by collars. Work of the later periods may be distinguished, apart from the design, by this feature, whereas the English and French smiths vigorously faced the hardest methods of work, and the German and Spanish smiths invented difficulties for the sheer pleasure of overcoming them. Notable centres of artistic ironwork were Florence, Siena, Vicenza, Venice, Lucca and Rome, where important pieces may be found in the form of gates, balconies, screens, fan-lights, well-covers and a mass of objects for domestic use such as bowl-stands, brackets and candlesticks.

In screen-work the favourite motif was the quatrefoil which is found with many variations over a long period of time. Early examples are strong and virile, later ones tend to weakness. The C-shaped scroll is used in many combinations. The churches and palaces of Venice contain many examples. Peculiar to Italy are the lanterns and banner-holders such as may still be seen at Florence, Siena and elsewhere, and the rare gondola-prows of Venice. Of the ironworkers of the early Renaissance the most famous was Niccoto Grosso of Florence, nicknamed *Il Caparra* because he gave no credit but insisted on money on account, who worked at the end of the 15th century. Vasari thus eulogizes him: "He was truly unique in his craft, and has never had and never will have an equal." From his hand is the well-known lantern on the Strozzi palace in Florence, repeated with variations elsewhere in the same city. Siena can show other lanterns and banner-holders attached to the façades of its palaces. Cressets are still to be seen at Lucca and a few other towns. The Victoria and Albert museum, London, contains two gondola-prows in fine pierced iron. Through the 16th and 17th centuries Rome produced much good work of a more virile character than that at Venice, and the same may be said of other cities. To the influence of the Rococo movement reference will be made later.

Spain.—Here the work of the Renaissance period reached a height of grandeur and magnificence attained in no other country. Of all the Spanish craftsmen the smith and the armourer were the busiest, especially during the 16th century. The particular manifestation of work in iron which for more than a century towered above all the others may be seen in the screens of monumental size (*rejas*) to be found in all the great cathedrals of Spain. These immense structures rising to 25 or 30 ft. show several tiers of balusters divided vertically by columns of hammered work and horizontally by friezes of hammered arabesque ornament, and are surmounted by a cresting which is sometimes of simple ornament, but more often a very elaborate design into

which are introduced a large number of human figures; shields of arms are freely incorporated, and the use of bright colour and gilding adds to their impressive beauty. The great balusters are always forged from the solid, and their presence in hundreds and possibly thousands demonstrates the extraordinary skill and power of the Spanish smith. The *reja* shut off the high altar of the church or cathedral, and a further opportunity came to the smith when the choir was moved westward. This necessitated a second screen to enclose the east end of the choir, and naturally this screen must be in no way inferior to that of the high altar. Thus in many cathedrals two of these monumental *rejas* are found facing one another. It was the smith's opportunity, and he availed himself of it to the full. His work may be seen in all the large cities of Spain—Barcelona, Saragossa, Toledo, Seville, Burgos, Granada, Cordova and many others. The screens follow the same lines of general design, but the balusters are sometimes of twisted iron and occasionally, as in the royal chapel at Granada, they are opened out some feet above the base into various devices—a method reminiscent of an earlier period. Similar work but on a smaller scale is found in gates, balconies and window-screens; wrought-iron pulpits also exist. The panels of hammered and pierced iron heightened with colours and gilding were used in connection with domestic architecture, and a note must be made of the fine nail-heads which ornamented many doors.

France.—The Gothic tradition survived in France until well into the 16th century, and was marked by the production of work of the highest skill largely in the form of locks, knockers and caskets of chiselled iron. The introduction of the Renaissance style made no great difference to the direction of the smith's art—a strange fact when it is remembered how Germany and Spain were fabricating works of enormous size and magnificence in wrought-iron. France, like England at that time, was content to make door furniture, in the form of locks, keys, bolts, escutcheons and the like, but did little work of any great size. A school of locksmiths came into being under Francis I. and Henry II., working from designs by Androuet du Cerceau in the 16th century and Mathurin Jousse and Antoine Jacquard in the 17th. The bows and wards of keys were of unusually intricate design, and the locks of corresponding richness. Representative pieces may be seen at the Victoria and Albert museum, London, among them the famous Strozzi key said to have been made for the apartments of Henry III., the bow of which takes the favoured form of two grotesque figures back to back. But as far as architectural ironwork was concerned, France remained almost at a standstill until the accession of Louis XIII. in 1610. Under that monarch, a worker at the forge himself, there came a great revival. It seemed to be uninfluenced from without, at first weak, as if feeling its way, but by the end of the 17th century it had attained a marvellous pitch of perfection. It proved to be the beginning of a new movement, the force of which made itself felt in the adjoining countries and inspired the workers with new energy which unfortunately at times dwindled into mere imitiveness. From the accession of Louis XIV. the French ironworkers must be acknowledged as the cleverest in Europe, combining as they did good and fitting design with masterly execution. Their designs were often very daring, reaching the limit of what was allowable in such a metal as iron. They recognized its great adaptability and took every advantage of it, at the same time being conscious of its limitations. Their opportunities were endless. Screens and gates were needed for parks, gardens and avenues, staircases for mansions and palaces, screens for churches and cathedrals. Among celebrated designers were Jean Lepautre, Daniel Marot and Jean Bérain. The earlier work is of a simple character, balconies for instance being in the form

of a succession of balusters, but as the smith became more conscious of his powers they took the form of panels of flowing curved scrolls rendered with a freedom never attained before, while constructive strength was observed and symmetry maintained. Enrichments were usually attached in hammered sheet-iron. These may be considered the distinguishing features of Louis XIV. work such as that at St. Cloud, Chantilly, Fontainebleau and elsewhere. But Louis XIV. surpassed all efforts in the work for his palace at Versailles.

The art of the blacksmith received a further impetus by the introduction of what is known as the rococo style. The movement initiated in 1723 was due to the imagination of two artists, Juste-Aurèle Meissonnier, architect, and Gilles Oppenord. There was no longer any symmetry or balance in the design, but fantastic and restless curves with a luxury of applied ornamentation. To the French smith it furnished the opportunity for a yet greater display of his skill. He was clever enough to secure a feeling of stability in his work by counterbalancing swirling masses or ornament with straight constructional lines; he knew how to introduce an iron screen of rococo style into a Gothic church or cathedral without giving offence to the eye or arousing any uncomfortable feeling of incongruity.

With astonishing manipulative power he worked as if the material under his hand were soft and pliable rather than solid and unyielding iron.

Later in the 18th century ironwork took on a more classical appearance, owing to the general study of ancient art, and many Greek and Roman details were introduced into the ornamentation. The amount of work executed was prodigious, and its beauty and cleverness may be seen in most cities of France.

As might have been expected, nearly all the adjacent countries were seized with the desire to imitate this French rococo style, England excepted. But their efforts in this direction were largely doomed to failure; the style was to them exotic, and consequently their imitations are, as a rule, unsatisfying. This is particularly true of the Italian rendering, which has lost the cohesion of the original design and lacks its bold workmanship; it fails to excite admiration. On the other hand, the German smith not infrequently caught the spirit of the French designer, and showed himself his equal in power of execution. Such work as that in the palace of the prince-bishop at Würzburg stands comparison with the French work of the period. Switzerland made an attempt in the French style of the end of the 18th century, and the results, though lacking the strength of the French work, are by no means unattractive.

RENAISSANCE PERIOD ELSEWHERE

England.—The development of the art during the Renaissance period was very uneven in the various countries of Europe. The English smith fell behind and seemed to have lost interest, producing no very great or important work. He continued to make iron railings and indulged in a number of balconies. His activities were more or less confined to small objects for architectural application such as hinges, latches, locks and weather-cocks. To this period belong the hour-glass stands of wrought-iron generally fixed to pulpits or some convenient adjacent column; over 100 still remain in their original position. In the reign of Charles II. a revival of larger work seemed imminent, and the rebuilding of the London churches after the great fire furnished an opportunity for making hat-rails, sword and mace stands, stair-rails to pulpits and finely decorated wrought-iron suspension rods for the great brass chandeliers with which the churches were provided. The English smith was neither idle nor incompetent, but he was waiting for an impetus and an inspiration for his work.

The opportune moment came towards the end of the 17th century. There was a growing interest in beautifying houses and laying out gardens and squares, and a consequent use for balconies, staircases and garden gates; the rebuilding of St. Paul's cathedral and the London churches was in full swing. The man to whom the credit is usually given for the revival of ironwork in England was Jean Tijou, a Frenchman who together with

RENAISSANCE IRONWORK IN GERMANY

1. German lock, characteristic of the Renaissance workmanship of that country. German smiths often designed such locks with complicated devices mainly to show their skill in executing them

2. German coffer. Example of the type of great chests executed by German smiths during the Renaissance period. They were covered with rich iron mountings of intricate design

many of his Protestant fellow-craftsmen had been forced to leave his country owing to the revocation of the Edict of Nantes in 1685. After some years in the Netherlands he came to England in 1689 where he enjoyed the patronage and favour of William III. and his queen. His most important works are to be seen in the immense mass of screens and gates with which he embellished Hampton Court palace for his royal patrons; they show an excessive amount of foliage and other ornament in sheet-iron beneath which the construction lines are almost lost, but Tijou was primarily rather an embosser than a smith. He executed work at Burleigh house, Stamford, and elsewhere; and probably by the queen's wish was associated with Sir Christopher Wren then engaged on the rebuilding of St. Paul's cathedral. Wren apparently was not very keen on ironwork, and probably exercised some restraint on Tijou with the result that his work at St. Paul's is more serious and dignified and freer from appendages than that at Hampton Court.

How far did the English smiths follow Tijou's lead? They possessed several useful qualities; they were careful observers and not mere copyists; they seldom lost sight of construction work or ignored the sense of stability that was essential; their more staid and serious temperament was reflected in their work; consequently they developed along lines of their own and produced a definite style. The early years of the 18th century saw the erection of many fine gates in London and the vicinity. One of the best known is that formerly at Devonshire house and now on the opposite side of Piccadilly. The names are known of several English smiths who proved themselves worthy successors of Tijou though in a definitely English style. Thomas Robinson was associated with him at St. Paul's where his work is easily distinguishable from that of Tijou. He also made the great garden screen at New college, Oxford, and perhaps the gates to Trinity college.

At Derby and in the neighbourhood Robert Bakewell executed the noble screen at All Saints church, the gates to Etwell hall, Melbourne, and much other work. William Edney made the screens in the churches of St. Mary Redcliffe and St. Nicholas, Bristol, as well as the gates to Tredegar park near Newport. Robert Davies of Wrexham executed gates for Chirk castle and other work in the vicinity. In London there may be studied a great amount of fine ironwork of the 18th century in the form of gates, railings, lampholders, door brackets, balconies, staircases; in almost every suburb may be seen gates and brackets. The precincts of the colleges of Oxford and Cambridge, as well as almost every old town in England, furnish a variety of handsome work. Throughout the 18th century the smith was a busy man; the general tendency of his work, unaffected by the rococo movement, was towards a less ornate but more characteristically English style, perpendicular, severe, lofty and commanding, as contrasted with Tijou's French love of richness and mass of details. So far from Tijou dominating English work, the native craftsman brought his ideas into line with the national temperament and taste which lay in the direction of simplicity and a thoughtful recognition of the limitations of the material. At the end of the 18th century the work of the architect brothers Adam shows a departure from true smithing; its slender delicate bars are enriched with rosettes, anthemion and other ornament in brass or lead. The effect is pleasing and harmonizes with the architecture with which it is incorporated.

Germany and Austria.—During the period of the Renaissance, ironwork in Germany showed a marked contrast to that of Italy. The metal was in use everywhere and for every purpose: for screens in churches, window grilles, stove guards, gates, fountain railings, well-heads, grave-crosses, door-knockers, handles, locks, iron-signs and small objects for domestic use. Smiths were their own designers, and more often than not planned intricate devices merely to show their skill in executing them. They recognized no limits to their powers, and so far as manipulative excellence went they were the foremost nation of Europe. But clever as their workmanship undoubtedly was, their designs frequently showed a lack of stability and a tendency to run riot. Thus many of their most imposing works consist largely of

filling of panels with elaborate interlacing scroll-work, and the sense of constructional and protective strength is lost sight of.

The greater amount of smiths' work is to be found in the southern parts of Germany. Iron bars of round section were most frequently used and the most common features are the threading backwards and forwards, terminations of flowers with petals and twisted centres, or of foliage or human heads. All of these characteristics occur with almost monotonous repetition, witnessing to the Teuton's skill in working, but also to his lack of imagination and power of design. The style may be studied in many German cities, *i.e.*, Augsburg, Nuremberg, Frankfurt, Salzburg and Munich; the work at Innsbruck is also well known.

The German blacksmith gave much attention to door-knockers and handles, enclosing them in pierced and embossed escutcheons, also locks of very involved mechanism. Mention must also be made of the great boxes erroneously termed "Armada" chests, sometimes covered with rich iron mountings and having a lock with many bolts spreading over the whole of the inside of the lid.

German influence made itself strongly felt in Switzerland where the working of iron had established itself in the 17th century. The intricate grilles and screens referred to above may be met with in the Engadine, and in more central parts of the country fine door fittings are found which are claimed, and probably with truth, to be of local manufacture. Scandinavia followed Germany in design and work. It must be remembered that ironwork had been an important industry in these countries from early mediæval times.

The Low Countries.—Holland and Belgium were influenced by their neighbours, but there is no work of the importance of that produced in France or Germany. Another metal, brass, seems to have provided the outlet for their energy, and they were content to confine their work in iron to objects for domestic purposes. Cranes for raising the covers of fonts continued to be produced for churches, and grilles of trellis-work for the tabernacles; screens were rare. The quaint streets of such towns as Bruges and Ypres were rendered more picturesque by signs hanging from brackets of wrought iron, such as may still be seen in the Rue du Fil, Bruges. The façades of houses were decorated with the date of their construction in large iron figures, or with wall-anchors whose device sometimes denoted the occupation of the owner; finials in the form of crosses or some fantastic device surmounted the gable ends; rich hinge and strap work strengthened the folding window-shutters.

Cast Iron.—The casting of iron seems to have had rather a limited existence. In England the earliest known piece is a tombstone in Burwash church, Sussex, which dates from the 14th century. And it was not until the close of the following century that the introduction of open hearths and fire-places brought fire-backs and fire-dogs into common use. Designs of backs were many and various, at first the royal arms and insignia, and later any kind of decoration, in fact any handy piece of ornament, was pressed into use. The most highly valued are those with the royal arms or crests, or with fine heraldry. Fire-dogs were simple, the uprights being in the form of a column or terminal figure, sometimes supporting a shield of arms. The making of fire-backs and fire-dogs was virtually confined to the Weald of Sussex where it came to an end with the close of the 17th century. The railing outside St. Paul's cathedral, London, is an old and important piece of cast work; however, it was not until the 19th century that cast-iron railings became general.

FIG. 4.—SOME OF THE VARIOUS TYPES OF HAMMERS USED IN WORKING THE IRON ON THE ANVIL

France also produced cast fire-dogs and fire-backs, the latter tending to greater refinement of style and execution than those of England. In Germany and the Low Countries fire-backs had their counterpart in the panels of stoves cast for the most part with scriptural subjects. Reference must also be made to the delicate "Berlin" iron jewellery cast in openwork with various designs at Ilsenburg in the Harz mountains, and as an act of patriotism substituted for the more precious metals to meet the exigencies of the Napoleonic wars. (See BRONZE.)

(W. W. W.)

MODERN EUROPEAN IRONWORK

A renaissance in the art of ironwork was achieved by the end of the 19th century. At first certain workers rediscovered this fine craft with all its strength, suppleness and complexity. The wonderful balustrade of Chantilly, a work of the Moreau brothers (1880), shows the results achieved in this respect. But this was not enough. It was necessary to return again to the underlying principles of the art in order to direct the skill of the technician toward logical achievement in the art. It was also necessary that the works so achieved should not be mere imitations of the past, but creations thoroughly of the present. It was necessary to rediscover a living style, and to this end the very conditions of artistic production had to be modified by the collaboration of workers in iron (artists and industrial workers), architects, and the public, united in a single love of this art that was being born anew. This enormous task, then imposed, has not yet been wholly accomplished. The union of art and of industry, in particular, is far from being sufficiently general; and we shall see that this was one of Edgar Brandt's preoccupations. But the principal effort was supplied in the last years of the 19th century, and in the first years of the present century; and it may be said that the battle, as a whole, had been won as early as 1905.

The employment of wrought iron had again been restored to common use. Architects once more employed it in all buildings of costly and elaborate construction. The public had become conscious of its elegance and its strength. New forms had appeared and the arts of metallurgy in particular had profited more happily than other arts by the researches that were then being made in the various forms of "modern style." Then, too, though the accomplishment of this period in all branches of the applied arts may very often seem questionable to-day, the underlying principles followed were generally excellent; and the difference between the artists of the present generation and their predecessors of 1890-1905 seems to consist especially in the fact that the more recent artists applied in a more logical manner the sound principles which their elders recognized, but which they failed to observe with sufficient consistency.

Émile Robert supplied more than merely strong, sane doctrines; his craft, too, was always magnificent; his works were well-composed and clearly wrought. When Brandt and his Paris workshop made their appearance, Robert had already freed iron decoration from the invariable acanthus and adorned it with the most charming flora, varied, light and wholly fresh. He had also divested it of the confused and anomalous ornamentation which to-day is so annoying in works like the Chantilly balustrade, and

he had returned to simpler structure. He had put away the file and given up metal-chasing; he paid due regard to the hammer marks, significant proofs of the struggle by which man controls rebellious matter. (We shall find that Brandt does not share Robert's systematic aversion toward chasing.) Robert was the unchallenged prince of metal-work. He exercised considerable influence because he added to the skill of the technician and the talent of the draughtsman the intelligence of the theorist who can reason about his art.

In 1905, a State school of ironwork was established in France. It had following, it was guided by fruitful principles, it had found original forms, and achieved some masterpieces; but it had within itself at least two elements of weakness—on the one hand (and often in Robert himself), an excessive tendency toward the fantastic; on the other hand, among too many artists, insufficient technical equipment.

Use of Machinery.—The modern craftsman, and Edgar Brandt probably more than others, makes use of the most perfect modern tools. His preliminary work is carried out with the pneumatic hammer, the stamper, the press. Machine-tools are employed for the assembling of parts; the work is divided according to the rules of modern industrial organization. Each of the different workshops carries out its special task. All the parts so created around the same motif are then assembled in the welding-shop. Here modern methods again economize time and effort, while supplying work so exact that it could not have been achieved in the past. Then the different motifs go to the shop to be set up. Finally the complete work receives, in the last workshop, its definitive surface, the operatives darkening the deeper parts and brightening up the others. Some persons disapprove of this use of machinery. They fear that iron will lose "its qualities of animated grace and living charm." They say that it debases iron to treat it with anything but the hammer. These are the words of the editor of *Bronzes d'Art Suisse* and were quoted by Émile Robert in the first article of his review, *La Feronnerie Ancienne et Moderne*, 1896. Brandt holds that these fears are entirely exaggerated because there is no question of abandoning the forge, from which is derived to-day a part of this life, grace and charm. To Émile Robert as to Jean Lamour, the forge is no longer a means, but an end in itself, outside of which, in their opinion, no processes can be recognized. Brandt, on the contrary, takes his place at the head of the school which may be called "eclectic," because for it the forge is only one means among several others equally interesting, and is to be employed or not according to the effect to be obtained and the purpose for which the object is

FIG. 5.—VISE AND TONGS USED TO HOLD IRON WHILE WORKING OR TO OBTAIN A GOOD GRIP ON OTHER TOOLS

intended. This school may also be called the "modern" school because it frankly adopts for its means the processes supplied by present-day science.

It is, then, of new effects that we must now speak. Brandt, for example, succeeds in decorating large frameworks with ornaments which support one another by their borders, without the aid of bars. Bars would formerly have been necessary to strengthen screens of this kind and, therefore, would have modified the character of the whole by dividing it into a large number of small sections. Acetylene welding allowed Brandt rapidly to

develop similar decorations of a breadth, suppleness and intricacy which literally could not be achieved in former days.

Modern technical processes open to creative activity a career hitherto unknown. As they grow more numerous, the artist's horizon is extended. His powers must increase in the same measure. A serious danger, that of mere facility, is now threatening. Every worker, without even a trace of genius, can use the acety-

FIG. 6.—CHISELS AND PUNCHES USED IN IRON WORKING

lene blowpipe, can operate the stamper, or the press, and not only display a deceptive virtuosity, but achieve productions in which art has no share.

Brandt's Workshops.—Innovations in technique correspond in detail to new methods of work. In general, it is a fact that no considerable work can to-day be produced by one man alone. The various machines, the large number of orders, and their importance make collaboration necessary. Brandt, whose beginnings were very modest, now plays the part of master of the work in his workshops; a little like the great painters, he directs some 30 draughtsmen. These different personalities add to the variety of material a variety of technique. (Brandt's principal collaborator is Favier, an architect.) None among them claims an idea as his own. While successive supervision secures perfect balance in these creations, their artistic quality is constantly refreshed by manifold researches which cause the underlying formula to stand out as they are established, and which thus sustain the fire of life. The master is obliged to supply a perpetual effort of concentration, for execution can only be achieved by obedience to the laws of unity and harmony, to the laws of architecture.

Prominent among the effective motifs which Brandt employs most frequently are pine-branches and two other motifs that seem to be his own creations. He uses them so systematically in his works and they assume so special a character that their presence alone would make us recognize their author. One is a plant of the Far East, the *Ginkgo biloba*. It is light and at the same time ornamental, lending itself with great suppleness to varied stylization, because it has along with its frail stems, tendrils and leaves, small fans which make a dark spot among the delicate lines. Secondly, and especially since the World War, Brandt shows a fondness for the decoration of vertical planes by a system of circles and scrolls.

But Brandt's originality lies less in the elements he employs than in the uses he makes of them. The variety of motifs, the mingling of a naturalistic flora with stylized flowers, his freedom of interpretation are so many characteristics common to Brandt's art and that of the generation of 1890-1905. In Brandt, too, are to be found the combinations of lines to which modern style has accustomed the eye, notably the metal rods, delicately sinuous, which suddenly curve back at very sharp angles. In turning over the pages of the art reviews of the first decade of the present century, we see Brandt's work, from his first attempts, integrating itself in a very normal manner with the productions of this period. This affiliation with his era does not, however, render less striking the fact that Brandt brought forth a new method of composition as harmonious as that of his predecessors was full of contrasts.

(R. RE.)

THEORY

The interest and charm which the most unpractised observer must find in the work of the early craftsmen in iron is due to

the fact that the metal was worked at a red or white heat. There was no time for measuring or copying a design save by the eye. Thus we get a spontaneity and a virility in forged work which expresses the life of the metal and gives the work its unexpected charm. These old craftsmen knew every branch of their work; they lavished as much skill and creative ability on a small handle as upon a great gate. No detail was overlooked, no matter how small or insignificant. This can be seen in various examples of their works, as in the fine old chests and boxes; the wonderful old locks, keys and other decorative hardware used in the great cathedrals. The sincere nature of craftsmanship and the proper use of materials for ends to which they are well adapted is little understood to-day. This is not because there is any lack of information on the subject, but because the perfection of the mechanical means of production at our disposal has blinded many to the simplicity of the means which produced the great works of the past.

Nevertheless there is more interest shown in arts and crafts to-day and more of a trend towards the use of them than ever before. Along with the good work comparable to that of the old masters, however, there is also a profusion of bad work. This bad work includes all the work which is tritely inventive and not truly creative. It is work done in an artificial manner; work which has no tradition, and is designed by those who do not understand the possibilities and limitations of the material in which they work. These people do not possess the true craftsman's training, and so the work is done in a mechanical way. Iron is sometimes of necessity artificially welded because of designs which are not properly conceived. The new ideas and new designs being introduced for this great craft are dangerous, for no work is good unless the material is used in the way it should be, and the designs made to suit that material.

Iron not only suggests security, strength, defence and durability, but lends itself to many beautiful and useful as well as ornamental purposes. But to-day these uses are being abused and ironwork is used promiscuously by those who try to establish a vogue in this craft. Much of the ironwork found on public buildings and in homes is for cheap show only, and little thought is given to the practical or decorative value of the work. A shop window may have a delicate grille or an ornamental gate, neither of which has any practical use whatsoever. It is conspicuously placed so as to attract the attention of the passer-by; the ironwork does not play into its architecture and is not in harmony with its surroundings.

There are certain fundamental principles of design and execution to be expected in all good ironwork, and the craftsman who is trained as a designer as well as a metal worker knows every one of these. Furthermore, works of the old masters should ever be before the student of this craft, and examples in museums and documents in libraries should help him in securing the true kind of inspiration.

Although a metal worker is able to furnish drawings suggestive of the style, scale, proportion and general lay-out of the design, his real study of details can only be accomplished on the anvil. It is this actual study in the metal which gives the work its unexpectedness and charm, and this can only come from a deep knowledge and love of the material. The making of beautiful ironwork cannot be fully described and illustrated on paper; it is often necessary for the craftsman to make sketches in iron, that is, make pieces in the actual material, before he illustrates on paper.

Although iron is the least expensive of all metals, there is no material which lends itself to more beautiful treatment. Neither is there a material which can be worked more quickly. It is one of the simplest and most direct, therefore one of the most difficult mediums in which to work. Very often the craftsman to-day is asked to slur over work which does not seem important, or which will not show, and is urged to make his work as cheap and showy as possible. Again, when a metal worker has a certain appropriation to meet for the work he is doing, he will carry out the design in the cheapest possible way in order to meet this appropriation. Instead, the craftsman should simplify the designs to meet

the allowance given, in order to make the work in the best possible manner.

Materials should not be taken from their proper spheres and used by tricks and illusions in other spheres. For instance, there are workers in iron who attempt to make this metal look like wood, gold or bronze. They finish it and work it so that it tricks the observer, distorting one material into the semblance of another, thereby losing both its simplicity and significance. Sometimes colour is used on metal work. A decorator often wishes to carry his colour scheme into lighting fixtures or other metal work, but although occasionally a little gilt may be used to give warmth to a piece of work, the colour should not be used with the idea of concealing bad workmanship. The most logical way to give colour to ironwork is to incorporate another metal, such as brass of a golden colour, applied or inlaid. Colour is also used as a background for ironwork. This is especially done in cases of pierced work or when the motif is of an open design. The ironwork is then backed with some material, such as an old red velvet. This may also be done in cases of mounting ironwork on woodwork, where the woodwork is stained so as to make a suitable background for the ironwork. (S. Y.)

MODERN TECHNIQUE AND PRACTICE

In casting decorative ironwork it is first necessary to adapt or conform the ornament to suit this class of work, then to prepare the patterns for the moulder. The production of the work now becomes a mechanical repetition, and whether the castings from each pattern be few or many, the results will always be an invariable sameness.

Wrought iron contains less carbon, is not as brittle and can be hammered or cut freely. Wherever this iron is worked by hand it is impossible to get an exact sameness or repetition, which in all cases creates a natural interest of variation in design.

Technique of Hammered Ironwork.—Hammered ironwork, the term commonly used, is often misunderstood by designers who are not familiar with this craft, and instead of a natural hand-wrought texture, the iron is defaced in a very unnatural manner. For instance, a man will place a section of rather smooth iron on an anvil and begin to disfigure it with uneven hammer blows, intending to make hammered iron. The designer, in this case, does not understand the proper use of the material.

This might be well illustrated in the case of a design composed of horizontal or perpendicular members of one-inch round iron. There should be no attempt to take a one-inch round section and abuse it as described, but instead a one-inch square section should be used, forging it as near to round as the human eye can measure. The bar will then possess the quality of hand craftsmanship and be far superior in character to any disfigured work or, on the other hand, to any machine-like perfection.

Execution of Work.—First, draw a sketch to a small scale, so as to obtain the general composition, proportion, silhouette and harmony with the design of surrounding materials or conditions. This sketch should then be developed into full size to obtain details of ornament, various sections and sizes of material, and a general idea of the method of making. At this time, careful consideration must be given to the practical use of the piece of work so that it may serve its purpose in the best manner possible. Workers in iron should always attempt to make everything direct from a drawing, rather than from models. When working from a model, the object becomes more or less a reproduction, whereas the drawings allow a greater opportunity to express the craftsman's individuality.

Studies or experiments in the actual material are now made, for here many things are revealed which could not possibly be shown on paper. The character of a twisted member or the flexibility of the material might be used for example to show how difficult it would be to conceive many such things in the drawings. For this reason the true craftsman should often make a fragment or portion of the ornament in the actual material first, and make the drawings later.

Tools Used.—Methods of working and the tools used to-day differ very little from those of early times. Machinery can some-

times be used for the greater convenience of the craftsman while working, thereby increasing his efficiency and permitting a great deal more work to be accomplished, yet it cannot be used in the actual making of any piece of work where the character of the craftsman is to be expressed. In comparing a forge of early times with one of the kind used to-day, a very good illustration of the valuable use of machinery can be shown. The purpose of the forge is to heat the iron to such a temperature as to make it flexible while working. The intense heat required cannot be obtained from the draught of an ordinary burning fire; therefore air must be blown to increase the draught. Fig. 1, a forge of mediaeval times, shows air being blown through a fire by a large bellows which must be operated by hand or foot constantly, to keep the draught flowing. Fig. 2 shows one of the types of forges used to-day. A machine blows the air into the fire, thus saving much labour and loss of time, which can be applied to better purposes.

On account of the great amount of variation and quick execution required in working with wrought iron, tools must serve many purposes, especially when certain work can be done only while the iron is hot. The anvil (fig. 3), is so designed as to permit any form to be forged upon it, with the proper use of various hammers, among which the most common used are shown in fig. 4. Wherever a strong grip is required to hold a tool or some smaller fragment of iron while working, the vice and different shaped tongs are used, as in fig. 5. There are also many kinds of chisels and punches, among which the most common are illustrated, and quite often it is necessary for the craftsman to make special tools for special occasions. Fig. 6 shows a few of these.

Iron in the Working.—Considering the broad scope of metalwork, it is easily seen that many processes occur in the working. A fine piece of ornament upon a Gothic box-lock must be treated far differently from the cresting over a large set of Gothic gates. The craftsman must feel the spirit of any design and use the correct sections of the material. In a gate or grille, for example,

FIG. 7.—VARIOUS WAYS OF WORKING IRON

the frame or main members must be square or rectangular in section, whereas the ornamental members may be diagonal or round.

The various methods familiar to the craftsman in working are forging, splitting and punching, incising, repoussée, carving, pierced work, spinning and stamping, welding, riveting, the use of collars or bands, and the different ways of finishing the material. The most fascinating work in metal is at the forge, where one who possesses the ability can produce work in iron with a spontaneity that cannot be obtained in any other way. Besides the making of

Twisted and forged bars, joined at top by curved rail. 6. Wrought iron lock for St. George's Chapel, Newport, R. I. 7. Door hinge of hand wrought iron for Washington Cathedral

scrolls, or various forms of open design, the greatest interest is due to the metal being so pliable. For an example, in splitting or incising the conventional decorative floral motif, the chisel naturally changes the section as it digs into the iron. This is also true when various punches are used, for as can be seen by the illustrations the iron will take another form, but the material or metal is never quite lost—unless it is severed entirely. The implements for splitting, punching and incising are shown in fig. 7.

Repoussé work applies to thin metal where the material is raised from the back or under side to the greatest depth or height required, and then modelled by the use of various tools and hammers to its required form. Wherever the repoussé ornament is not very high, or requires little modelling, the work can be done with tools of various shapes, with a block of lead (fig. 8) used as a base, while hammering. If the design contains a great deal of modelling, as in a mask, after the metal has been raised to its greatest height from the back, lead is poured in to fill and act as a foundation. A margin of metal is bent around the lead so as to keep it in position, and the modelling or shaping of the face is done on the outside surface, following a fine outline scratched on the iron to act as a guide.

Incised and carved methods are used where a surface of metal requires certain decorations or designs. Of the two, carved metal requires the greater care, as it should be used only for small, fine details, and must be done in a suggestive way to preserve the metallic feeling, rather than as if copied from a sculptured model.

Another method of decoration is to pierce or cut certain designs or forms out of the thin metal so that either a coloured background or natural light will show the silhouette in the ornament. Many beautiful forms can be used to advantage in this kind of work. It is also correct to stamp certain objects in thin metal, providing the design is made for this purpose. This is usually done where a great quantity of the required design is needed, thus making a die for the exact form. By placing the die on the metal and striking it the required stamping is made. Very often the stamped object is worked over by hand to give it a hand-wrought appearance, but this is not correct and is never done by the true craftsman.

Many beautiful forms and shapes are obtained by spinning various metals. For example, a sphere or ball, which is meant to be perfectly smooth and true, can be very easily spun in two halves and then assembled. This is much more practical than attempting to hammer or beat the metal by hand.

The foremost methods of fastening or tying one fragment of iron to another are welding, riveting and the use of collars or bands of various forms. As can be seen by the illustrations of these methods, each one has a different effect upon the design; therefore each must be used in its proper place. In the case of welding, the desired forms are forged from a long piece of iron, and then, as in the case of a ring, the two ends are merged together as one. Another example of welding, which shows the great variety in this process, is that of a number of pieces of iron being welded together rather than split from one piece of metal. An illustration of welding, riveting and the use of collars or bands is shown in fig. 9.

Finish.—Without the correct finish the full beauty of metal-work cannot be appreciated. Iron, like any other material, must be finished in accordance with its use or purpose, and must also receive a certain amount of care at various times. Interior iron-work should possess the natural finish, which is of armour colour, and the metal can be polished as bright as silver. After the correct lustre is obtained, an oil or wax is applied; then, in the course of time, the object receives a very beautiful patina. In the case of exterior work, the iron should be only slightly polished and left more with the natural colour obtained from the forge.

Uses.—Whether in the home, in churches, or in various public buildings, iron will be found serving many and various purposes. Furniture, stairways, lighting fixtures, hinges, door-knobs, grilles,

certain kinds of cutlery and fireplace equipment of this metal are used in homes. In the church, pulpits, crosiers, the crucifix, sanctuary lamps, baptismal fonts, lecterns and alms-boxes are works of the craftsman at the anvil. The gates or doors of many public buildings open to reveal bank-screens, grilles, enclosures and railings, serving their purposes and illustrating the beautiful character of iron.

INDIAN AND INDONESIAN

Iron and Steel.—Iron may not have been known before about 1000 B.C., but steel was certainly in use in the 3rd century B.C., and it may be safely asserted that by this time all or almost all the metals and alloys and the technique of working and decorating them in various ways were well known. With this premise, it will be desirable to proceed at once to describe from a practical point of view the various methods of working the useful metals, as traditionally practised in India.

The manufacture of iron and steel by primitive small scale methods has survived in southern India and Ceylon to the present day. The iron is smelted directly from the ore, and true carbon steel of high quality is made by melting the iron with a small proportion of green wood in a clay crucible heated to a high temperature. The slag heaps of ancient furnaces are common and the processes have probably been in use for more than two millenniums, but it is unknown whether they are of indigenous invention or acquired. In southern India iron immediately succeeds stone as a material for tools and weapons, and prehistoric iron weapons begin to come into use about 500 B.C. Alexander received a gift of Indian steel from the Punjab chiefs; steel dating from the 2nd century B.C. has been found at Besnagar and in Ceylon, and tempered steel is referred to in the *Ummagga Jātaka*. Indian iron and steel weapons have been famous throughout the middle ages, and the steel was exported to Persia and further west,

where it formed the material of the Damascus blades of the Saracens. Buddhist begging-bowls are generally made of iron. The wrought iron pillar of Delhi, set up about A.D. 415 by Kumāragupta I., in honour of his father, is over 23 ft. in height and weighs more than 6 tons; it demonstrates the abilities of Indian metal workers in handling larger masses of material, for not until the latter part of the 19th century could anything of the same kind have been made in Europe. There are other large iron pillars at Dhar and at Mt. Abu. The wrought iron finials of Burmese stupas are often extremely elegant.

The decoration of iron and steel, apart from the ornamentation of the handles of weapons, which may be made of other materials,

takes various forms. The shapes of weapons are usually of great elegance, and if they are further decorated by engraving or carving, this is never permitted to interfere with their utility. The most remarkable carved steel weapons are those of southern India (Tanjore), the Dekhan, and Rajputana; but the art extended to Farther India and Indonesia, as will be seen in any of the fine chiseled kris from Bali. Decoration by the application of a second metal is effected by damascening or encrusting. In *koftgārī*, or true damascening, deep or shallow grooves are cut in the surface of the iron or steel to be ornamented, and gold or silver wire

FIG. 9.—VARIOUS METHODS OF JOINING PIECES OF IRON

being laid in the grooves is hammered until completely united with the ground metal, which may then be smoothed and polished, showing the required design, which may consist of geometrical or floral ornament or an inscription. In encrusted work, the required form is first carved on the surface of the ground metal, the edges of the carved area being slightly undercut, then a thin plate of gold or silver of the same size is applied and beaten down on to the carved surface, while the edges of the applied metal, being slipped into the undercut groove, are held tightly as a result of the hammering.

CHINA AND JAPAN

Iron began to take its place in the brilliant bronze age culture of China about 500 B.C. By the end of the 2nd century of the present era bronze weapons had been almost completely supplanted, while iron had been generally substituted for bronze in common use in utensils and vessels of various kinds, tools, chariot-fittings and even small pieces of sculpture. These were commonly cast in sand-moulds, were patterned after bronze prototypes and were typical in style and decoration of the Han period.

The Iron age in Japan is supposed to have begun in the 2nd century B.C., though the chief early remains are weapons from the dolmens of the 2nd to the 8th centuries A.D. The Japanese iron founder attained a considerable skill at an early date and acquired a social position which was never attained by the bronze caster, or by the iron workers in China where the bronze age tradition was much stronger.

From the 9th century iron increasingly took the place of bronze in China as a material for sculpture, especially in the north and under the Sung dynasty. The few extant examples from the 11th century and later show work done on a larger scale and in coarser technique than the bronzes, though the modelling is usually more naturalistic.

Several iron pagodas, ranging in size from miniature models to towers 30 or more metres in height, and dating from the 10th to the 14th century, give further evidence of the dexterity of the Chinese iron caster. These imitate in detail both the structural and decorative effects of the more common tile-roofed brick pagodas. Iron for temple furniture has long been in use, and a large number of the braziers, censers, caldrons and bells found to-day in the temples are of iron.

In China in the 17th century the iron picture was developed, the craftsmen seeking to reproduce in permanent form through the medium of wrought iron the effects of the popular ink-sketches of the master painters. When completed, these pictorial compositions were mounted in windows, in lanterns or in frames as pictures. When in the latter form a paper or silk background often bore the signature and seal of the maker, heightening the resemblance to a painting. The craft flourished in Anwei province and is still practised, though with less patience and fineness than formerly.

Embellishment of Armour.—It is apparent that iron has been used in China chiefly as a substitute or imitative medium, worked often with great skill but with little artistic invention. In Japan, however, the iron worker developed a distinctive and original means of expression and high artistic attainment in furniture for the sword. With the rise of feudalism and the establishment of the samurai class after the wars of the 12th century, the

equipment of the warriors became an object for the efforts of the artist. At first these efforts were devoted to the embellishment of defensive armour, but from the 15th century the sword became the centre of attention. The blade is not properly part of our subject, but in the mountings, especially the guards (*tsuba*), we find exquisite artistry expressed chiefly in iron. A remarkably soft and pure variety of the metal especially free from sulphur was employed. It was worked by casting, hammering and chiselling; and innumerable surface effects were obtained by tooling, inlaying, incrustation, combination with other metals and patination by various, usually secret, processes. Simple conventional patterns, crests and pictorial designs were the bases for the decoration. As these were often furnished by painters or designers the criterion of connoisseurship in Japan is the unsurpassed technical quality of the handling of the iron itself. With the promulgation of the edict of 1876, prohibiting the wearing of swords, this art came to an end, but the skill of the Japanese iron worker may still be noted in numerous small decorative objects.

IRON MASK (*masque de fer*). The identity of the "man in the iron mask," one of Louis XIV.'s political prisoners who died in the Bastille in 1703, is a famous historical mystery. In 1698, Saint-Mars, the new governor of the Bastille, brought with him from Pinerolo in Piedmont a prisoner whom he kept masked and whose real name was not known. This prisoner died on Nov. 19, 1703; and his name was entered in the register of Saint Paul as "Marchioly," "aged about 45." Even during his lifetime, legend grew up around this mysterious person, and Saint-Mars himself admitted circulating "fairy tales" (*contes jaunes*) about him. He was soon suspected of being connected with the royal family; whilst Voltaire added immensely to the legend by describing the mask as of iron, and the man as a natural brother of Louis XIV.—a theory which Dumas in the *Vicomte de Bragelonne* did much to popularize. It was even asserted that this Bourbon prince had a son who founded the Bonaparte family in Corsica; whilst other wild speculations identified him with Monmouth, Beaufort, Fouquet, and even Molière.

It is now evident that the man in the mask was either Count Mattioli or "Eustache Dauger." Mattioli was the Mantuan minister who attempted to sell to France the frontier fortress of Casale, but revealed the transaction at the last moment, and was eventually secured by Louis' agents. In spite of the support of M. Funck-Brentano and of the tempting argument from the name under which the prisoner was buried—in fact, almost certainly a false name—it is difficult to accept a solution which seeks to identify the mysterious "mask" with a man whose career and identity were so well and so generally known. The other candidate, much more likely, is Eustache Dauger; but to admit his claim is only to postpone the difficulty. In fact, after the researches of Monsignor Barnes and Andrew Lang, the principal problem for the investigator remains: who was Dauger? Several theories have been put forward on very slight evidence. It seems clear that he was a Catholic and not an Englishman; but the fact that at a time of emergency he was allowed to act as valet to Fouquet has drawn a red herring across the trail; and Andrew Lang has used the phrase "he is only a valet" in a letter from Louvois to Saint-Mars as the basis of a theory identifying the man with the valet of a Huguenot emissary to England. It is, however, unlikely that the phrase referred to the masked prisoner at all. Monsignor Barnes has identified him with the Abbé Pregnani, involved in the religious affairs of Charles II., and for that reason possessing dangerous information. That the prisoner was sent to Pinerolo from Dunkirk favours the idea of some connection with England; and Monsignor Barnes at first went on to claim that the abbé was a natural son of the English king. This hypothesis linked up the problem with a second—that of James de la Cloche—and soon

proved untenable.

The problem is probably more difficult than important. The mask itself was of no harder material than velvet; and the man would surely not have been used as a valet if he had been near to the blood royal. There is, however, a fascination in the peculiarly interesting evidence, and in the possible theories which may be constructed from it. The period was one in which intrigue was at its height, and the affairs of individuals were so intertwined with those of states that every figure of importance appears as the centre of a labyrinth whose key may be anywhere in western Europe. Romantic imagination has done the rest.

BIBLIOGRAPHY.—A good introduction to the subject and its materials can be gained from A. S. Barnes, *The Man of the Mask* (1912) (with appendix of documents); F. Funck-Brentano, *Revue Historique* LVI. (1894), and Andrew Lang, *A Valet's Tragedy* (1903).

IRON MOUNTAIN, a city of Michigan, U.S.A., on the western edge of the Upper Peninsula, near the Wisconsin State line (the Menominee river), at an altitude of 1,160ft.; the county seat of Dickinson county. It is on Federal highway 2, and is served by the Chicago and North Western, the Chicago, Milwaukee, St. Paul and Pacific, and (for freight only) the Wisconsin and Michigan railways. The population was 8,251 in 1920 (30.5% foreign-born white) and was estimated locally at 14,000 in 1928. The Chapin mine, employing 700 men, and other rich iron mines, are in the vicinity; and the Ford Motor company has mines, lumber mills and plants here, with an aggregate force of about 2,500. Iron Mountain was settled in 1879 and incorporated in 1887. When the first train came in (July 1880) the population was 150, and by 1887 it had grown to 8,000.

IRON RIVER, a city of Iron county, Michigan, U.S.A., in the western part of the Upper Peninsula, 5 m. from the Wisconsin State line (the Menominee river). It is on Federal highway 2, and is served by the Chicago and North Western and the Chicago, Milwaukee, St. Paul and Pacific railways. The population was 4,295 in 1920 (27% foreign-born white). Twenty-five active iron mines in the county in 1926 produced 4,271,358 gross tons of ore. Lumbering and agriculture also are important in the region, and the city has several manufacturing plants. Iron River was settled about 1875 and was incorporated in 1926 with a city-manager form of government.

IRONSIDES, a nickname given to one of great bravery, strength or endurance, particularly as exhibited in a soldier. In English history Ironside or Ironsides first appears as the name of Edmund II., king of the English. In the Great Rebellion it was first given by Prince Rupert to Cromwell, after the battle of Marston Moor in 1644. From Cromwell it was transferred to the troopers of his cavalry, those "god-fearing men," raised and trained by him in an iron discipline.

IRONTON, a city of southern Ohio, U.S.A., on the Ohio river, 142m. E.S.E. of Cincinnati, opposite Russell, Ky.; the county seat of Lawrence county. It is on Federal highway 52, and is served by the Chesapeake and Ohio, the Detroit, Toledo and Ironton and the Norfolk and Western railways, and by river boats. The population was 14,007 in 1920 (92% native white) and was estimated locally at 22,500 in 1928. The hills, which rise from the river bottom, are rich in iron ore, coal, limestone and fire-clay. The city has large mining and lumber interests, and important iron manufactures and cement works. The output of its factories in 1925 was valued at \$10,878,919. Ironton was settled in 1848 and incorporated as a city in 1851.

IRONWOOD, a city of Gogebic county, Michigan, U.S.A., in the western tip of the Upper Peninsula, on the Montreal river. It is on Federal highway 2, and is served by the Chicago and North Western, the Duluth, South Shore and Atlantic and the Soo Line railways. The population was 15,739 in 1920 (37% foreign-born white) and was estimated locally at 20,000 in 1928. It is the metropolis of Gogebic county, which in 1926 mined 5,756,380 gross tons of iron ore, and some of the largest mines are within the city limits. Lumbering, stock-raising and farming also are important. Ironwood was settled in 1884, chartered as a city in 1889, and in 1890 had already a population of 7,745. Since 1925 it has had a city-manager form of government.

IRON-WOOD, the name applied to several kinds of timber, the produce of trees from different parts of the tropics, and belonging to very different natural families. Usually the wood is extremely hard, dense and dark-coloured, and sinks in water. Several species of *Sideroxylon* (*Sapotaceae*) yield iron-wood, *Sideroxylon cinereum* or *Bojerianum* being the *bois de fer blanc* of Africa and Mauritius, and the name is also given to species of *Metrosideros* (*Myrtaceae*) and *Diospyros* (*Ebenaceae*).

West Indian iron-wood is the produce of *Colubrina reclinata* and *C. ferruginosa* (*Rhamnaceae*), and of *Aegiphila martinicensis* (*Verbenaceae*). *Ixora triflorum* (*Rubiaceae*) is the *bois de fer* of Martinique, and *Zanthoxylum Pterota* (*Rutaceae*) is the iron-wood of Jamaica, while *Robinia Ponacoco* (*Leguminosae*) is described as the iron-wood of Guiana. The iron-wood of India and Ceylon is the produce of *Mesua ferrea* (*Guttiferae*). The iron-wood tree of Pegu and Arracan is *Xylia dolabriformis* (*Leguminosae*), described as the most important timber-tree of Burma after teak, and known as *pyingado*. The endemic *bois de fer* of Mauritius, once frequent in the primeval woods, but now becoming very scarce, is *Stadtmaninia Sideroxylon* (*Sapindaceae*), while *Cossignya pinnata* is known as the *bois de fer de Judas*. In Australia species of *Acacia*, *Casuarina*, *Eucalyptus*, *Melaleuca*, *Myrtus*, and other genera are known more or less widely as iron-wood. Tasmanian iron-wood is the produce of *Notelaea ligustrina* (*Oleaceae*), and is chiefly used for making ships' blocks. The iron-wood or lever-wood chiefly used in North America is the timber of the American hop hornbeam, *Ostrya virginica* (*Betulaceae*). In the United States various other trees are also known as iron-wood, as the desert iron-wood (*Olneya Tesota*), of south-western deserts; the Catalina iron-wood (*Lyonothamnus floribundus*), of southern California islands; the southern iron-wood (*Bumelia lycioides*), of the south-eastern States, and several subtropical trees found near the coast from Florida to Texas. In Brazil *Apuleia ferrea* and *Caesalpinia ferrea* (both *Leguminosae*) yield a kind of iron-wood, called, however, the *Pao ferro* or false iron-wood.

IRONY, a form of speech in which the real meaning is concealed or contradicted by the words used (Gr. *εἰρωνεία* from *εἶπω*, "one who says less than he means"). It is particularly employed for the purpose of mockery or contempt. The Greek word was used for an understatement in the nature of dissimulation. It is especially exemplified in the assumed ignorance which Socrates adopted as a method of dialectic, the "Socratic irony" (see *SOCRATES*). In tragedy, what is called "tragic irony" is the device of making a character use words which mean one thing to him and another to those acquainted with the real issue.

IROQUOIS (ir'q-kwö or -kwöi). During the colonial period the Iroquois were, north of Mexico, the native American people of greatest political importance. The name has been adopted for the entire linguistic family of which they were the most conspicuous representatives. The *Iroquoian family* occupied three territories, a northern, southern, and south-eastern. In the northern area there lived, besides the Iroquois proper, the Conestoga or Susquehanna in Pennsylvania; the Erie and Neutrals south and north of Lake Erie; the Tionontati or Tobacco nation, and the Huron (*q.v.*) in Ontario; and a series of tribes on the St. Lawrence later merged with the Huron. The southern division consisted of the Cherokee (*q.v.*); the south-eastern, of the Tuscarora (*q.v.*), Nottoway, and Meherrin. These tribes were all semi-sedentary, practised maize agriculture, lived in villages palisaded in time of need, were divided into totemic, matrilineal clans, and manifested tendencies toward the formation of fairly cohesive confederacies, in which blood lineages integrated in clans, clans in tribes, and tribes in leagues. Religion was relatively simple on the ritualistic side, and somewhat interwoven with political ceremonial. Warfare was frequent and ruthless, captives being either tortured, enslaved, or adopted. In all these traits the Iroquoian tribes resembled the Muskogian (*q.v.*), and differed somewhat from the Algonkin (*q.v.*), who were patrilineal, on the whole less given to farming, less developed in political sense and cohesiveness, and less aggressive in warfare though perhaps equally brave. It is therefore likely that a culture of Algonkin type, probably carried by Algonkin peoples, once prevailed uniformly over north-eastern

United States and eastern Canada, and that into this there intruded cultures and peoples of south-eastern origin, first the Mound Builders (*q.v.*) in the Ohio valley, and later the northern Iroquoians in the region of the lower Great Lakes; the aboriginal Algonkin, however, surviving as a fringe completely surrounding these north Iroquoians. In New York, where archaeological exploration has been unusually well co-ordinated, its results confirm this view. The most notable point of difference between the northern Iroquoians and the Cherokee and Muskogi of the south-east seems to be the somewhat higher status of woman among the former.

LEAGUE OF THE IROQUOIS

The *Iroquois proper* of history comprise the Mohawk, Oneida, Onondaga, Cayuga, and Seneca, living in this order from east to west in central New York. According to tradition, Hiawatha, a Mohawk, and Dekanawida, reputed a Huron by birth, induced the five tribes to form a league which preserved the integrity of each, but united them in a common council, and common ceremonies, with a fixed number of chiefly delegates from each tribe. In a sense this was representative democracy; and each delegate was elected; but he was chosen by the members of a lineage as representative of that lineage, and therewith of a clan and tribe, so that a group-hereditary principle prevailed. Each such clan delegate had further to be approved by the tribal and league council. There was no head of the league; and deliberate action usually became effective only upon unanimity. Apparently this league differed from other native confederacies, which were common in the eastern United States and south-eastern Canada, in being more precisely defined and organized. It allowed of the development of a tradition of political sagacity independent of the occasional superior individual, and this in turn permitted the fruits of wars to be conserved instead of dissipated, with success still further strengthening the established policy.

The league in its historic form is estimated to have been constituted only a generation before the coming of the whites among the Iroquois, about 1570. During this formative period the Iroquois drove from the St. Lawrence a series of tribes who joined the Huron. In the first half of the 17th century they harried and wore down the Conestoga, their kinsmen on the south, and the Algonkin tribes on their east. Their most striking successes came about the middle of the century, after they had acquired guns in friendly trade with the Dutch. In rapid succession they attacked and broke up four Iroquoian tribal aggregations to the west of them: Huron, 1648–50; Tionontati, 1649; Neutral, 1650–51; Erie, 1653–56. Parts of some of these nations were transplanted among the Iroquois, where they gradually became absorbed; remnants fled, scattered, joined one another or alien tribes, and became lost to history. The completeness of their destruction was perhaps partly due to their habit of concentration in large palisaded towns; the more scattered Algonkin generally withstood the Iroquois longer. The Illinois suffered badly at the hands of the Iroquois, the Delaware submitted in 1720, and all Virginia was harassed. Only the distant Ojibwa set a boundary to the Iroquois conquests in the west, and the Cherokee and Catawba of North Carolina to the south, though the latter were almost worn down in the struggle. The Tuscarora, an Iroquoian tribe of North Carolina who had voluntarily moved to New York, were formally admitted into the confederacy about 1715, this being henceforth the League of Six Nations. Other tribal remnants of various origin sought shelter with them, and these, with the absorption of captives, helped to make up the Iroquois losses in constant warfare. At that, the five tribes probably never numbered more than at present, 16,000.

From the first, the Iroquois were consistent and bitter enemies of the French, who had shown amity to their traditional foes. They remained in friendship and trade with first the Dutch and then the English, who utilized them against their Indian enemies and the French, whereas the Iroquois profited in fire-arms, other trade articles, and the sanction if not protection of civilized powers. They undoubtedly greatly hampered French extension from Canada southward; but for the consistent Iroquois check, the English colonies would have been flanked behind by the

French and the history of their development might have been very different. This is a remarkable achievement for a savage people that never put into the field an army greater than 2,000 men.

When the American Revolution broke out, the league as such took no part, but most of the tribes sided with the British, and were defeated by the Americans. The Mohawk and Cayuga mainly withdrew to Ontario, many of the Onondaga and Seneca remained on reservations in western New York, and part of the Oneida after a time moved to Wisconsin. The present population is considerably diluted with white blood; two-thirds are on Canadian soil, including the descendants of seceding groups won over to the French interest at the end of the 17th century. A shadow of the league is still perpetuated as a ceremonial form.

See L. H. Morgan, *League of the Iroquois* (1851); *Ancient Society* (1877); H. Hale, *The Iroquois Book of Rites* (1883); J. N. B. Hewitt, *Bur. Am. Ethn. Rep.* xxi. (1903), xxxii. (1918). (A. L. K.)

IRRATIONAL: see NUMBER, *Irrational*.

IRRAWADDY or **IRAWADI**, the principal river in the province of Burma, traversing the centre of the country, and running throughout its entire course in British territory. It is formed by the confluence of the Mali and N'mai rivers (usually called Mali-kha and N'mai-kha, the *kha* being the Kachin word for river) in 25° 45' N. The N'mai is the eastern branch. The definite position of its source is still uncertain, and it seems to be made up of a number of considerable streams, all rising within a short distance of each other in about 28° 30' N. It is shown on old maps as the Lu river of Tibet; but it is now quite certain that the Tibetan Lu river is the Salween, and that the N'mai has its source or sources near the southern boundary of Tibet, to the north-east or east of the source of the Mali. At the confluence the N'mai is larger than the Mali. The general width of its channel just above the confluence is 350 or 400 yards. In the rains this channel is filled up, but in the cold weather the average breadth of the river is from 150 to 200 yards. The N'mai is practically unnavigable. The Mali is the western branch. Like the main river, it is called Nam Kiu by the Shans. It rises in the hills to the north of the Hkamti country, in about 27° 50' N. Between Hkamti (*q.v.*) and the confluence it runs in a narrow channel through continuous hills. About 1 m. above the confluence it is 150 yd. wide in January and 17 ft. deep, with a current of 3½ m. an hour.

Steam launches can only ascend from Myitkyina to the confluence in the height of the rains. Native boats ascend to Laikaw or Sawan 26° 2' N., all the year around, but can get no farther at any season. From the confluence the river flows in a southerly direction as far as Bhamo, then turns west as far as the confluence of the Kaukkwe stream, a little above Katha, where it again turns in a southerly direction, as far as the great bend near Mandalay, where it is joined by the Myit-nge. Thence it follows a westerly course and is joined by the Mu stream—an important source of water for irrigation in the Shwebo district—on the north bank. Beyond Myinmu it again assumes a southerly direction and is joined by its chief tributary, the Chindwin, described below. Between the confluence and Mandalay the river varies in width from 50 to 4,000 yards. It is narrowest in the three well-known "defiles." The third or upper defile lies between Myitkyina and Bhamo and is entered 3 m. below Sinbo by a channel only about 50 yd. wide and below this, throughout the defile, it averages about 100 yd. wide.

At the "Gates of the Irrawaddy" at Poshaw two prism-shaped rocks narrow the river to 50 yd., and the water banks up in the middle with a whirlpool on each side of the raised pathway. All navigation ceases here in the floods. The defile ends at Hpatin, and below this the river widens out to a wet-season channel of 2 m., and a breadth in the dry season of about 1 mile. At Sinkan, below Bhamo, the second defile begins. It is not so narrow nor is the current so strong as in the third defile. The narrowest place is more than 100 yd. wide. The hills are higher, but the defile is much shorter. At Shwegu the river leaves the hills and becomes a broad stream, flowing through a wide plain. The first defile is tame compared with the others. The river merely flows

between low hills or high wooded banks. The banks are covered at this point with dense vegetation, and slope down to the water's edge. Here and there are places which are almost perpendicular, but are covered with forest growth. The course of the Irrawaddy after receiving the waters of the Myit-nge opposite Sagaing, as far as 17° N. lat., is exceedingly tortuous. Below the junction of the Chindwin and Irrawaddy, the tributary streams throughout the dry belt are but small, though some, especially those in the Minbu district, are important sources of water for irrigation, and others, like the Yaw river, are used for floating teak logs to the main river. At Akauktang, where a spur of the Arakan hills ends in a cliff 300 ft. high, the river enters the delta, the hills giving place to low alluvial plains, now protected on the west by embankments. From 17° N. lat. the Irrawaddy divides and subdivides, converting the lower portion of its valley into a network of intercommunicating tidal creeks. It reaches the sea in about 16° N. lat. by nine principal mouths. Practically no water, however, now reaches the sea through the western and eastern mouths (the Bassein and Rangoon rivers respectively) though these are the ones used by sea-going ships to reach the ports of Bassein and Rangoon.

The largest tributary of the Irrawaddy is the Chindwin, its entire course being in Burmese territory. It is called Ningthi by the Manipuris. The Chindwin is formed by the junction of the Tanai, the Tawan and the Tarôn or Turông, but it is still uncertain which is the main stream. The Tanai has hitherto been looked on as the chief source. It rises in about 25° 30' N. and 97° E., on the Shwedaung-gyi peak of the Kumôn range, 12 m. N. of Mogaung, and flows due north for the first part of its course until it reaches the Hukawng valley, when it turns to the west and flows through the middle of the plain to the end of the valley proper. There it curves round to the south, passes through the Tarôn or Turông valley, takes the name of the Chindwin, and maintains a general southerly course until it enters the Irrawaddy, after flowing through the entire length of the Upper and Lower Chindwin districts.

The Tarôn, Turông or Towang river seems to be the real main source of the Chindwin. It flows into the Hukawng valley from the north, and has a swift current with a succession of rapids. Its sources are in the hills to the south of Sadiya, rising from 10,000 to 11,000 ft. above sea-level—mountains that are covered at least with winter snows. Below the Hukawng valley the Chindwin is interrupted at several places by falls or transverse reefs. At the village of Haksa there is a fall, which necessitates transshipment from large boats to canoes. Not far below this the Uyu river comes in on the left bank at Homalin, and from this point downwards the steamers of the Irrawaddy Flotilla Company ply for the greater part of the year. The Uyu flows through a fertile and well-cultivated valley, and during the rainy season it is navigable for a distance of 150 m. from its mouth by steamers of light draught.

The area of the catchment basin of the Irrawaddy is 158,000 sq.m.; the total length of the main river from its known source to the sea is about 1,300 miles. Throughout its course, except through the defiles, it is full of islands and sandbanks; its waters are extremely muddy, the mud being deposited partly in the delta, in part being carried far out to sea. The river commences to rise in March; about June it rises rapidly, and attains its maximum height about September. The total flood discharge is between four and five hundred million metric tons of 37 cubic feet. From Mandalay up to Bhamo the river is navigable a distance of nearly 1,000 m. for large steamers all the year round; but small launches and steamers with weak engines are often unable to get up the second defile in the months of July, August and September, owing to the strong current. The Irrawaddy Flotilla Company's steamers go up and down several times a week, but the mails are carried to Bhamo by a ferry-boat from the railway terminus at Katha.

The river Irrawaddy itself supplies no main irrigation works; the great value of the river is as a highway. It is the only means of reaching such important centres as the oilfields of Yenangyaung and Singu, which are served as yet neither by road nor railway. The Irrawaddy is nowhere bridged, though crossed by two steam

ferries (at Henzada and at Sagaing) to connect the railway system on either bank. (L. D. S.)

IRREDENTISTS, an Italian patriotic and political party which was prominent in the last quarter of the 19th century. The name was formed from the words *Italia irredenta*—unredeemed Italy—and the party had for its object the emancipation of all Italian lands still subject to foreign rule. The lands which they claimed as Italian were south Tirol (Trentino), Görz, Istria, Trieste, Tessino, Nice, Corsica and Malta. The agitation was, however, mainly superficial, and sank into insignificance when the French occupation of Tunis in 1881 offended the Italians deeply, and their government entered into those relations with Austria and Germany which led to the Triple Alliance. The name "Irredentists" is also used of any other nationalist group aiming at the emancipation of any of their countrymen subject to foreign control.

IRRIGATION. The artificial application of water to land (Lat. *in*, and *rigare*, to water or wet).

Normally vegetation grows on soil saturated by rain. Where rain is seasonal, deficient or practically nonexistent, as it is, for instance, in Egypt, the desiccation of the soil prevents vegetable growth. In such areas irrigation can give even better results than nature herself produces, because water is given just when it is wanted, instead of at the fitful times of rainfall. Irrigation water must be "sweet" or fresh. All ordinary fresh water contains a small percentage of salt. Vegetation, however, will tolerate a much larger percentage, more especially if the drainage is good. The use of irrigation as an aid to the growth of vegetation is indeed an ancient art, as is shown by the biblical reference: "And a river went out of Eden to water the garden" (Gen. ii. 10). The probabilities seem to point to Egypt as its place of origin. The irregularity of watering, caused by the small though potent degree of variation in height of each annual Nile flood, would prevent the Egyptian from regularly garnering such crops as were naturally producible in specific areas, and he must quickly have realized that he could take steps to correct the variation by artificially supplying water directly, by his own labour, to the fields he found it most convenient to depend upon, and thus have begun, at least in the Nile valley, the art of irrigation. The paintings and sculptures of ancient Egypt do show that the peasantry baled up water at least 4,000 years ago. From Egypt the art may have spread to the ancient empires whose territories are now covered, at least in part, by the modern State of Iraq. Certainly the conditions on the Euphrates and the Tigris are comparable to those on the Nile.

Carthage, Phoenicia, Greece and Italy may have followed the same example. India and China are also countries which have progressed in this early art. The westward sweep of the Moors is no doubt responsible for its development in Spain. Wherever the Mohammedan penetrated, and circumstances proved favourable, he introduced irrigation.

METHODS OF LIFTING WATER BY CONTINUALLY RENEWED LABOUR

Shadoof.—Baling up water by hand (obviously the earliest system and that by which many acres are still watered throughout the world) is slow and expensive in labour. Inventive minds soon devised mechanical aids. About the earliest must have been the contrivance made up of two upright poles with a cross-beam joining them at a point 8 ft. or 10 ft. above ground level. Over the cross-beam (if there is no cross-beam, from the meeting point of the two poles) is slung a long tapering pole, the greater part of its length being on one side of the uprights. From the tip of the longer and slimmer portion is hung a rope ending in a skin or bucket, to the shorter end is attached a mass of clay or other weight sufficient to counterbalance the bucket when full of water, the worker pulls on the rope until the bucket dips into the well or stream; when it is filled he lets go and the counterbalance causes the bucket to rise with its water. In India this contrivance is known as the *denkli* or *paecottah*. In Egypt it is called the *shadoof*. Where the soil level is high above the water the lift is overcome by installing extra shadoofs, the lower one feeding the

next higher and so on until the required height is attained. One shadoof can irrigate about 4 acres.

Sakia.—Another ancient aid to irrigation is the water-wheel known in Egypt as the sakia, and the harat or Persian wheel in northern India. In this instrument a beam is attached horizontally to a toothed wheel. To the outer end of the beam, cattle, usually a pair of oxen, are yoked and travel in a circular path, pulling the

FIG. 1.—PRIMITIVE METHOD OF IRRIGATION EMPLOYED BY THE MEXICANS

beam with them, thus making the wheel revolve. The latter engages in its teeth a similar vertical wheel which thus also revolves, and in turn lifts up an endless rope to which buckets are attached at short distances apart. As the machine turns, the buckets, one by one, dip into the well in which they are hung. When the buckets reach the top of their course they tilt over and empty into a prepared channel leading to the fields. When empty the buckets descend again, mouth downwards for another fill. One such machine can irrigate 5 ac. to 12 ac., dependent on the height of the lift. The not unpleasing sound made by the movements of this contrivance is said to have influenced the music of the East.

Archimedes' Screw.—Probably the most intriguing of all these anciently devised implements is the screw invented by Archimedes of Syracuse about 200 B.C. This consists of a wooden cylinder, 1 ft. or 2 ft. in diameter, in which there is placed a corkscrew-shaped diaphragm running from end to end. The cylinder is usually about 8 ft. to 12 ft. long, and is placed with its lower end in the water and its top lying inclined on the bank of the canal or stream, the lift usually being about 3 feet. To the centre point of the diameter of the cylinder there is a crank-handle attached, by which the whole contrivance can be revolved, the act of revolution causes the water to proceed up the internal screw and flow on to the soil. Shadoof, sakia and screw are all still in constant use.

Power Plants.—Not until the arrival of the age of steam, which brought with it the power to drive pumping plants of all kinds, has human and animal life been relieved of a great part of the duty of directly lifting water on to the soil. Irrigation makes use of such pumping plants in all sizes, ranging from the tiniest 3 h.p. or 4 h.p. engine, up to the huge installations whose power can be measured in thousands of h.p.'s., and capable of dealing with great volumes of water. The introduction of oil as a fuel has naturally been taken advantage of in many cases as a substitute for steam.

METHODS OF LIFTING WATER BY PERMANENT WORKS

Canals.—Man early saw that he could assist nature by taking water out of a river at a point higher upstream than immediately opposite his own particular field, and thus take advantage of the fall or slope between these two points. In the case of the Nile the fall is only about 6 in. in 1 mile. As some slope must be given to the water in a canal to make it flow, and if this is, say, 3 in. to 1 m., only 3 in. can be gained in each mile of length and thus land can be irrigated that is somewhat higher in level than could be commanded by the river directly opposite any particular

field. Canals, to be really effective, must take off a river usually many miles upstream of the areas they serve. In the case of the Nile they are only dug deep enough to catch a supply from the river when in flood or artificially heightened by weirs.

Weirs or Barrages.—That the weir, or, as it is often called, the barrage, as an aid to lifting water is old, there is no doubt, yet only in modern times has the idea been used to any great extent. A weir or barrage is a structure built across a river, not for the purpose of storing water, but simply to produce a higher level of water on the upstream side of the building, to enable it to flow easily into canals taking off from either bank and command the land with free flow of water. Thus the weir or barrage is a method of providing for doing, practically for ever, without further labour, what hitherto had to be done continuously by the aid of manual or mechanical work. The artificial upstream level is produced by shutting as much or as many as may be necessary of the doors or gates with which each structure is provided. As these buildings are most often necessary in those parts of a river's course where there is no other foundation than sand or silt, very naturally no great heading up can be provided for. A head of 20 ft. is seldom reached. More usually the upstream levels are only increased by 10 ft. to 14 feet. Whatever heading up of the waters is required, it is never so great as to interfere with the silt-carrying property of the river. Fortunately in such situations great heights of lift are seldom necessary.

WORKS TO ASSURE SUPPLIES OF WATER

Reservoirs.—Man did not long remain content with the supplies river or well provided him with. He must early have realized the advantage of storing water against times of shortage, as rivers and wells run low if they do not even run dry. At what date reservoirs first came into use as an additional aid to a regular supply is unknown, the remains of ancient reservoirs throughout the world, however, testify to the antiquity of the idea; the earliest form probably consisted of earthen embanked reservoirs, or tanks as they are known in India. The tank suffers from the disadvantage of retaining all the silt contained in the water stored in it. In time this leads to practical obliteration and a new tank has to be constructed elsewhere. Reservoirs with masonry dams also were built. These too became filled with silt in time, and not until recent years, and until the Periyar dam was built in India, with sufficient sluiceway near its base to pass all the flood waters and only arrest the later clean supply, was the problem met and a reservoir constructed which, in a silty river area, could be depended upon to keep itself clear of detritus. The most magnificent example is the Aswan dam in Egypt where the whole of the heavy Nile flood passes through the building without dropping any of its silt content and only clear water is stored; thus guaranteeing a practically perpetual life to the reservoir notwithstanding the vast volume of water it annually contains.

FORMS OF IRRIGATION

Basin System.—There are two main forms of irrigation. In the more ancient system the area to be served is surrounded by embankments, and is thus called a "basin"; into it a canal leads the waters from the river until a depth of 3 ft. or 4 ft. is attained. In Egypt many of the basins are of great size, some covering as much as 50,000 ac.; the water is run off after a time and the exposed area is sown with crops which need no further watering to bring them to maturity. The system obviously originated in the fact that a river can be easily made to give a supply once a year during its flood period, whereas enormous expense would be required to make it do so at other times. It happens, also, that the production of food crops follows the flood season in rivers like the Nile; very naturally, therefore, the system devised was one which took advantage of a river's flood season.

Fig. 2 will serve to explain this system of irrigation, the firm lines representing canals, the dotted lines embankments. It will be seen, beginning on the east or right bank of the river, that a high level canal from an upper system divides into two. The right branch waters all the desert slopes within its reach. The left branch passes by a syphon aqueduct, under the main canal of the

system, taken from the river close at hand (and therefore at a lower level). This left branch irrigates the high lands bordering on the river. In years of very favourable flood this high level canal may not be wanted at all; irrigation could be done from the main canal, and with this great advantage, that the main canal water would carry with it much more silt than would be got from the tail end of the high level canal, which left the river

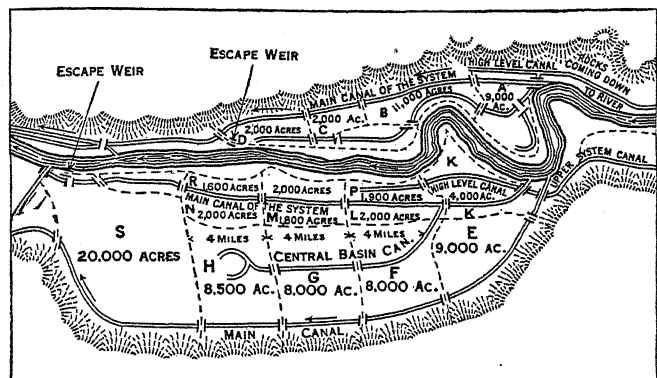

FIG. 2.—MAP OF A BASIN SYSTEM OF IRRIGATION
A, B, C, D, flat lands irrigated by the main canal
E, K, P, L, large basins irrigated by the high level canal
F, G, H, S, basins irrigated by the central basin canal

perhaps 25 m. further upstream. The main canal flows freely over the areas C and D and if the flood is good, over B and a part of A. It is carried round the next desert point, and to the north becomes the high level canal. The masonry works required for this system are a syphon to pass the high level under the main canal near its head, bridges fitted with sluices where each canal passes through an embankment, and an escape weir at the tail of the system, just south of the desert point, to return the water to the river.

Perennial System.—The other system where a perennial supply of water is made use of is also fed by canals, but in this case the canal system is enormously developed when compared with that of the basin system. In the latter one canal only may be required to feed many basins, this one canal running simply through the higher level basins and terminating at the middle of the last one of the series. In the perennial system branch canals lead off from the main canal, and lesser branches lead off from the main branches, and so on in ever decreasing size until, as a last branch, the smallest runlet is reached. The cost of this canalization is great, but the returns are correspondingly valuable, as usually about two crops can be grown under it instead of the one crop only per annum of basin irrigation.

The diagrams (figs. 2 and 3) show a perennial canal system. Only the main canals and branches are shown as such a system may extend over any distance up to 200 m. or even more. This plan also shows how efficient drainage should be provided between the canals. The more detailed canalization from the branches is shown in fig. 4.

DISTRIBUTION AND VOLUME OF WATER REQUIRED

Distribution.—Where irrigation is carried on throughout the whole year its proper distribution becomes a most important operation. It is generally considered sufficient if during any one season one-third of the area commanded is actually supplied with water. This encourages that rotation of crops which is a necessity of good farming, and also the lying fallow of some part of the soil, which also appears to be a necessity in hot and arid countries during a portion of each year. Some crops, of course, require water much oftener than others, and much depends on the temperature at the time of irrigation. During the winter months in Northern India magnificent wheat crops can be produced which have to be watered only twice or thrice. But to keep sugar cane, indigo, or cotton alive in summer before the monsoon sets in in India, or the Nile rises in Egypt, the fields should be watered every 15 to 20 days, while rice requires an almost constant supply of water.

Volume of Water.—Even if the crops grown under irrigation were in each case identical, the conditions in different countries and at different seasons are so variable as to preclude a statement of volumes of water which would suit all places and conditions. The volume of water varies with its quality, purpose and temperature, with the climate, season, soil, sub-soil, drainage, slope, aspect and crop. Two hundred tons to 600 tons of water may be given per watering under the perennial system, whereas the one watering of the basin system may take 3,000 tons to 6,000 tons per acre. But whatever the volume, its accurate estimation for the purpose of proper division in each particular case is essential to ensure the maximum area being fed from any particular source.

Measurement.—Measurements of the volume of water flowing in a river or canal were formerly obtained by noting the speed of objects floating with the stream. In the last 30 years current meters replaced floats and give more regular results, but it was not definitely known, just as in the case of floats, whether these results indicated actual volumes or not. This doubt has now been set at rest by the calibration of water passing through the sluices of the Aswan dam in Egypt soon after its construction in 1902. This calibration was itself definitely proved correct by the full scale measurements of the volume passing in a given time by one sluice into a tank built below the dam about 1905; thus the amount of opening of the sluices indicates the actual volume of water passing in the river, at any level, to within an error of 1%. It was subsequently found that current meter discharges, repeated a few times to obtain a mean result, and taken simultaneously with the measurements at the dam, gave very similar results to the latter; thus the accuracy of current meters also became proved. It has further been shown that the data obtained from carefully prepared small scale models can be relied upon as correct to within a very small percentage of error. This indicates a very great advance on the previous state of such knowledge.

MINOR SYSTEMS OF IRRIGATION

Water Meadows.—In addition to the two major systems of irrigation, there are a number of minor systems with special objects in view. Nowhere in England can it be said that irrigation is necessary to ordinary agriculture, but it is occasionally employed to stimulate the growth of grass and meadow herbage in what are known as water meadows. On the Avon, in Wiltshire, and the Churn, in Worcestershire, these may be traced back to Roman times. This irrigation is not practised in the drought of

BY COURTESY OF THE U.S. BUREAU OF RECLAMATION

FIG. 3.—DIAGRAM SHOWING IRRIGATION PROPERLY COMBINED WITH DRAINAGE

summer, but in the coldest and wettest months of the year. The water employed being warmer than the natural moisture of the soil, proves a valuable protection against frost. Before the conversion of land into water meadows care must be taken to have good drainage, a sufficient supply of water, and of good quality. It might be thought that drainage would be unnecessary, but porous sub-soils or efficient drains do not act merely by carrying away stagnant water which would otherwise cool the earth, encrust the surface, and retard plant growth. They cause the soil to perform the offices of a filter; thus the earth and the roots of vegetation absorb the useful matter from the water which passes through it.

Warping.—Warping is the name of a system which produces its results by a temporary use of the basin form of irrigation. In this system the suspended solid matters are of importance as a material addition to the ground. That is to say, the solid matter is used to make a new surface of soil on which, when a satisfactory depth of it is obtained, and where adequate drainage is provided, crops may be grown in the ordinary man-

ner from rainfall. The warping practised in England is almost exclusively confined to the overflowing of land lying below tide mark within the districts commanded by estuaries or tidal rivers. A good example of the process may be seen when sailing up the Trent from the Humber to Gainsborough. Here the banks of the river were constructed centuries ago to protect the land within them from the encroachment of the tide. The warping begun in the 18th century has become a regular system in recent times. Large masonry sluices, with strong doors to shut off the tide when necessary, may be seen in both banks of the river. From these sluices canals are carried in some cases many miles inland through the flat country to the point previously surrounded by embankments within which the muddy waters are to be allowed to spread. As the waters settle the mud is deposited and the clear water returns with the falling tide to the bed of the river. Spring tides, of course, are preferred. Peat mosses of the most sterile character have been by this process covered with soil of the greatest fertility and converted into firm and fertile fields. Three years are often spent in this process. One year in warping, one year drying and consolidating, and one year growing the first crop. The latter is generally hoed in by hand, as the mud is at first too soft to admit of horse labour. The drainage of peat soils has the effect of lowering the whole level through shrinkage of the peat. It is said lowering to a depth of 10 ft. to 12 ft. has occurred in some of the marsh areas drained. Of course warping to some extent makes up for the lowering caused by drainage.

Sewage Farming.—Many towns situated in inland districts, instead of passing their sewage into the nearest stream, deal with it under modern settling tank systems, from which the effluent is run off into small canals, which irrigate suitable cultivable areas. The yield of crop produced is great, as such waters contain a very high percentage of nitrogenous matter. The drainage from the city of Cairo, for instance, is said to be 30 times as valuable as the equivalent of Nile water even in flood time, when the latter bears what is said to be its fertilizing silt.

Drainage.—An absolutely necessary concomitant to irrigation is drainage of the soil. In few areas does nature provide this without further artificial aid. For many years the supply of irrigation water was the only problem considered by engineers; the disastrous results which have followed in many, if not in all, cases, from a neglect of the provision of adequate drainage has, however, awakened everyone to the necessity of supplying it if fields are to continue fertile. Very recent work on this subject in Cambridge shows its importance and, incidentally, that in the case of the Nile it is not alone the addition of Nile silt to the surface of the soil which induces fertility, but the period of rest and drainage which, in particular, the basin system of irrigation provides to a very great degree, that is so valuable. The perennial system can also be so arranged as to give a suitable, though much shorter, period of rest. Only education, experience and scientific teaching can prevent a farmer from overcultivating. In most irrigation systems, however, the collective opinion of the majority can compel the restriction of the supply of water at times when scientific opinion shows that the land should be left fallow.

COUNTRIES WHERE IRRIGATION IS DEVELOPED

Egypt and the Sudan.—In describing the areas where irrigation has been developed in various countries it is only necessary to give a more detailed statement regarding one of them, and Egypt has been selected, as its very life depends on its irrigation, whereas in most other cases irrigation is subsidiary to rainfall. Ancient as irrigation is in Egypt, it was never practised on a really scientific system until after the British occupation. As everyone knows, the valley of the Nile outside the Tropics is practically rainless. Yet it was the produce of this valley that formed the chief granary of the Roman empire. Probably nowhere in the world is there so large a population per square mile depending solely on agriculture, and so free from the risk of a season of drought or of flood. This is due to a remarkable property of the Nile. The regimen of the river is nearly constant. The season of its rise and fall, and the height attained by its waters, vary from year to year to a comparatively small extent. Each year

the river begins to rise in Egypt about the beginning of June, attains its maximum in September, diminishes at first rapidly, and then more slowly, until the following June brings a new cycle. A late rise is not usually more than about three weeks later than an early rise. From the lowest level in summer to the highest level in flood the rise is, on an average, about 30 ft. at Aswan. The highest flood may be about 5 ft. more, and this extra height may mean disaster to life in Lower Egypt if the Nile banks are not carefully maintained so that they may contain the flood between them, train it to the sea, and not allow of its spreading over the land, except as permitted for irrigation. The lowest flood since 1737 occurred in 1913 and rose only to about 8 ft. below the average. The next lowest Nile occurred in 1877, and caused widespread famine throughout Upper Egypt, as 947,000 ac. remained barren there because the water did not rise high enough to flow properly into the canals. The land revenue lost in that year, as it is chargeable only on areas watered, was £1,112,000. The thorough remodelling of the whole system of canals since 1883 abolished all danger of famine and disaster in other low years, and the loss of revenue in each of these years was comparatively slight. In 1907, for instance, when the flood was nearly as low as in 1877, the area left unwatered was little more than 10% of the area affected in 1877. The area of all Egypt is over 240,000,000 ac., of which about 5,200,000 ac. are cultivated; but about 7,200,000 ac. can be cultivated from the waters of the Nile. All the remainder, lying in plateau and hilly country high above the Nile, must continue in its present inhospitable state of bare rock and sand until a climatic change occurs.

Irrigation During Low Nile.—The khedive, Mehemet Ali, was advised to deepen the canals of Lower Egypt to draw water at even the lowest stage of the river, a gigantic and futile task for, as they were not laid out on scientific principles, the deep channels became filled with silt during the succeeding flood, and all the excavation had to be done over again year after year. Since they were never dug deep enough throughout to draw water from the very bottom of the river, the canals occasionally ran dry altogether in the month of June, when the river was at its lowest, and when, being the month of greatest need, water was most necessary for the cotton crop. Thus large tracts which had been sown, irrigated and nurtured for, perhaps, three months, perished in the fourth, while all the time the required precious Nile water was flowing uselessly to the sea. The obvious remedy was to throw a weir or barrage across each branch of the river to control the water, and so heighten the levels at which it flowed that it could pass into canals taken from upstream of the weirs. The task of designing such weirs was committed to Mougél Bey, a French engineer of ability, who constructed them at the apex of the Delta, about 12 m. north of Cairo, in 1861. The barrage consists of masonry platforms on which are built two stone bridges—one over the Damietta branch of the river having 71 spans, the other over the Rosetta branch, having 61 spans of 16.4 ft. each. The height of pier is 28.7 ft. from flooring to spring of arch, the latter being placed just above the surface level of a maximum flood. The movable gates placed between each of the piers were intended to increase the river level above the buildings by about 15 ft. The river supply could thus be made use of, and flow through a whole network of canals branching off the main canals taken off the river upstream of the barrage, and thus feed all Lower Egypt. For many reasons it would be unfair to blame Mougél because the work was condemned as being really a hopeless failure, until it fell, in 1884, into the hands of British engineers, with Sir Colin Scott Moncrieff at their head. The latter resolved that the barrage could be strengthened sufficiently to carry out its work. The strengthening works which enabled this to be done mainly concerned the masonry platforms, which were thoroughly grouted and extended. Further strengthening by means of subsidiary weirs erected immediately downstream of the various weirs was carried out, and the building as a whole made capable of carrying a designed head of water against it. Since 1901 a second weir has been constructed opposite Zifta, across the Damietta branch of the Nile, to improve the irrigation of the Dakhiliya province.

The first alteration in Upper Egypt from the basin to the perennial system of irrigation was due to the khedive Ismail, who acquired vast estates in the province of Assiut, Miniah, Beni Suef and the Fayoum, and resolved to grow sugar-cane on a large scale, and with this object constructed a canal, named the Ibrahimia, taking out of the left bank of the Nile at the town of Assiut, and flowing parallel to the river for about 200 miles. This canal had one defect; it could not receive water in summer, as the river then was too low. It was decided, therefore, to construct a barrage across the river for the same purpose as the Delta barrage, viz., to increase the level so that summer water could be made available as well as flood water. This structure was built at Assiut on a design very similar to that of the Delta barrage.

PLAN OF FIELD CHANNEL IRRIGATION

It consists of a wide masonry platform carrying a bridge of 111 arches each 5 metres' span, with piers of 2 metres' thickness. In each opening between piers are fitted two gates. The weir is about half-a-mile long. The work was begun at the end of 1898 and finished in 1902, and cost about £800,000.

The flood of 1902 was extremely low and would have, if unaided, resulted in great loss of crop and revenue; fortunately Mr. Webb (afterwards Sir Arthur Webb) grasped the significance of the power of control the new weir gave him over the height of the river upstream of the work, and used it for the novel purpose of heading up the flood. It was the bold action of a competent engineer and was more than amply justified by the result. Further strengthening of the downstream toe of the floor became necessary, but was not costly. This system of heading up low floods has ever since been continued at Assiut, and its advantages have been the justification for the construction of the Esna barrage in 1909, at the cost of about £900,000; this work renders the basin lands of the Kena province independent of a bad flood, but, like the Assiut barrage, it can be ultimately used to give summer water when such is available. Another similar structure with a similar object is now being erected at Nag Hamadi. With its completion Upper Egypt need never fear the effects of a low flood. It may be as well to say here that while a bad flood means low level in the river, yet no flood has ever been so low that there has not been enough water flowing to carry out all the irrigation required. What is really necessary is to make the water that is available flow at a high enough level, and it is this these barrages accomplish.
